To the Editor:—In this age of progress, when new inventions and discoveries follow one another so rapidly, it easily happens that some of the most marvelous are overlooked. Few in our profession are ignorant of the Roentgen rays and their value, but many are still unfamiliar with the Omnicura and Bracelin's bactericide, and with Mr. J. J. Russell, the genial and enterprising agent who offers these remedies to the public and the profession. This is not to be wondered at, as long as physicians continue to look for information in medical journals only, instead of perusing the “voice of the people” in the Chicago *Tribune*, where the marvelous cures effected by the Bracelin remedy may be daily read by a discriminating public.

But like the violet which blooms in modest retirement, the “Omnicura” blushes almost unknown and unnoticed: our profession still lingers in total ignorance of its virtues, the *Tribune* does not herald it forth; only pedestrians who cast a passing glance at the windows of Mr. J. J. Russell's Panaceum, seem to be aware of its existence.

The lamentable state of ignorance among physicians concerning these remedies, has induced me to write this letter to the *JOURNAL*. The Chicago *Tribune* only has so far taken an active interest in this subject, and as long as the department stores do not furnish medical reading, it will be the only organ deserving

our admiration for its enterprise in that direction. Without it the Bracelin cure would waste its sweetness on the desert air; but nurtured in its bosom under the fostering genius of Mr. J. J. Russell, it has come to blossom like an octopus at the side of the omnicura. Armed with such weapons he defies diphtheria, scarlet fever and pneumonia, and he would not lose his head in an epidemic of Asiatic cholera. In such an event his fertile mind would not fail to provide the Bracelin bactericide with suitable pumping implements, and the “Voice of the people” would have to be issued in extra bulletins to keep pace with scientific progress.

To those who have failed to keep up with medical advance and are ignorant of the Bracelin cure, I owe a few words of explanation. Mr. J. J. Russell, who is one of the most remarkable men in this country, has informed me that its wonderful power as a bactericide is due to the presence of chlorin deprived of its irritant qualities by a process discovered by Dr. Bracelin, after severe mental effort extending over fifteen years. Dr. Gehrman, of the Chicago Health Office, has demonstrated that it differs from all known antiseptics in one particular: The latter kill bacteria; but the bactericide does not. I have myself verified the presence of a slight amount of hydrochloric acid and menthol in the air inhaled from it; but chlorin is totally absent, which is a great advantage, because the latter is very irritating.

The difficulties that meet young physicians in their efforts to gain a livelihood are daily increasing. Many a one starts out with a bold outlook in the future, who soon realizes that all his hopes rest on quicksand only, and if he does not succeed in making a bold strike at fortune, he sinks deeper and deeper in the slough of oblivion. To such I can give only one advice: Write a letter to the *Tribune* glorifying the Bracelin cure, and enduring fame will henceforth attend him. His name will continue to appear in public print as a man of genius and learning, his fame will be only second to that of Dr. Bracelin and of his accomplished agent, Mr. J. J. Russell, and with theirs it will be handed down to future generations.

But on no account let any one write criticisms against the Bracelin cure; it can not stand it. And for this reason the *Tribune* defends it like an enraged lioness protects her defenseless offspring. Woe to him who does! He will be covered with infamy and everlasting ignominy.

But why does the *Tribune* glorify the Bracelin cure only and not the omnicura? Why praise the good and ignore the best? Reader, I am no judge in such matters, but I am convinced that the *Tribune* is actuated only by the purest philanthropic motives. It is in the broadest sense a truly representative journal, in which the high standards of honesty, morality and patriotism that prevail in Chicago, are blended in exquisite harmony.

MARTIN MATTER, M.D.

“A Wisconsin Diploma Mill.”

MILWAUKEE, WIS., April 27, 1896.

To the Editor:—I would like to reply to Emil Bories, M.D., whose interesting communication appeared in your issue of April 25.

Section 1771 of the General Statutes of Wisconsin, as amended by chapter 220, laws of 1883, and chapters 180 and 352, laws of 1887, provide that, “Three or more adult persons, residents of the State, may form a corporation in a manner provided in this chapter to conduct, or pursue, or promote any one or more of the following named purposes.”

Among many things it provides for obtaining a charter, which is to be issued by the Secretary of State, for “establishing and maintaining schools, high schools, academies, seminaries, colleges, universities, lyceums and the like.” Also for the “Establishment and maintenance of any benevolent, charitable or medical institution, hospital or asylum, etc.”

Under the provisions of this statute, the founders of the "Wisconsin Eclectic Medical College" obtained their charter.

Section 2340 of the general statutes provides for annulling corporations, and places the power in the hands of the attorney general in the State to take action in such cases.

Section 2341 provides as follows: "An action may be brought by the attorney general, or by any private party, in the name of the State, on leave granted therefor by the supreme court upon cause shown, for the purpose of vacating the charter, or annulling the existence of any corporation created by or under the laws of this State, except a municipal corporation, whenever such corporation shall:

"1. Offend against any of the provisions of any law, by or under which it shall have been created, altered or renewed; or

"2. Violate the provisions of any law, by which such corporation shall have forfeited its charter by abuse of its powers; or

"3. Whenever it shall have forfeited its privileges or franchises by failure to exercise its powers; or

"4. Whenever it shall have done or omitted any act which amounts to a surrender of its corporate rights, privileges or franchises; or

"5. Whenever it shall exercise franchises or privileges not conferred upon it by law."

I desire to state that very active efforts have been put forth by the health department of the city of Milwaukee to have this charter annulled, and the attorney general is at present engaged in pushing the matter to the courts as rapidly as possible.

U. O. B. WINGATE, M.D.,

Sec'y State Board of Health.

The Optician's Side of the Case.

MINNEAPOLIS, MINN., April 22, 1896.

To the Editor: Your editorial remarks of April 18 on the "Ambition of the Optician," while thoroughly orthodox and unimpeachable, are yet suggestions of a controversy that has two sides to it.

We have a very virtuous feeling when we have pocketed \$5 or \$10 for a ten minutes' examination of a healthy presbyope, and yet we know perfectly well that an intelligent optician would have given the same glass and saved the patient our fee.

Of course there is the contingency of glaucoma, or some other disease of the eye, and so we can not admit the propriety of allowing the optician to meddle with eyes at all. Unfortunately for our pretensions the opticians and the public know us too well. They know that many of us give patients a less thorough, and in results, a less satisfactory examination than the better class of opticians and "refractionists," and we know that such superficial work is not to be charged up to "post-graduate fiends" so called. Some of the worst refraction work I have ever run across has come from eminent professors of ophthalmology in the East and West. For example, Rev. C. consulted an eminent professor on the New England seaboard and was given R. 3. L. a plain glass. Soon after an oculist in a large city in New York State gave him R. and L.

1.59 C. horizontal. Supposing, of course, that he could find relief in Chicago, he consulted Professor , who gave him prisms, 3 degrees each eye, base in. That finished him. He placed his collection of glasses, which he had never been able to wear, in the family museum, and determined to keep clear of oculists.

Having inveigled him into my office I found his refraction to be corrected as follows:

R. 2 .75 C. 70 deg. temporal 20 20
L. 2 C. 70 nasal 20 20

With this correction he has been able for the past two years to read and write with some degree of comfort. Of course, the case was difficult, but distinguished oculists are supposed to be equal to the emergencies. The man wanted relief and was,

willing to pay for it. He paid his money and he got in return the impression that he had been swindled.

A gentleman lately went to an optician and requested an examination of his vision. The optician soon found a high degree of hyperopia and a considerable degree of astigmatism, and thereupon advised that an oculist should be consulted. The man said he "would be —" if he would see an oculist. He "had already paid Dr. —," naming a prominent professor of ophthalmology, nearly a hundred dollars and had got nothing for it. Dr. — had given him:

R. 1. C. 15 deg. - Pr. 3 deg. base in. L. — 1.

My optical friend gave him

R. + 1.50 = + .50 C. 90 deg.

L. + 1.00 = + .50 C. 90 deg.

and he has relief from his asthenopia and a settled conviction that Dr. — had "worked" him, and that oculists are shysters.

On a recent visit to a large Eastern city I found one of my friends wearing glasses prescribed by an optician. She had suffered from headache and had consulted a prominent oculist who, after a prolonged examination, informed her that she had no need of glasses. Later, while under treatment in Boston, she was advised by her physician to consult an *optician* who partially corrected a compound hyperopic astigmatism and cured her headache.

Twenty-one years ago, after having wasted two years valuable time through the incompetence of my medical advisers, East and West, I consulted a brilliant young oculist in the middle West. He used atropia, informed me that I had hypermetropia, and gave me + 1 D. which I found worse than useless. A few months later a kind providence sent me to Drs. Williams and Ayres, of Cincinnati, where I got my first lesson in honest, careful refraction work, and a lesson that I shall never forget. At the end of ten days Dr. Williams gave me a correction for my astigmatism (simple) and I was cured.

My experience has given me a hearty contempt for specialists who do superficial and dishonest work, and when I see such men forcing themselves into prominence by pure unadulterated gall, often disgracing chairs in medical colleges, and not infrequently securing positions of the highest honor in medical societies, I think I see the reason why medical men are so little respected, and why they have so little influence in securing legislation.

If the conditions as regards refraction work are unsatisfactory to oculists, they have themselves to thank for it in a large degree. This is certainly true in the northwest, where a few prominent men have abused the confidence of, and corrupted the profession, blackmailed the opticians and plundered the public. The public have at last learned that opticians and "refractionists" give them as good service as shyster oculists and with much less expense. The result is, oculists find themselves doing very little refraction work, except what is sent to them by opticians, and we have the delightful spectacle of professors of ophthalmology soliciting business and demanding commissions from opticians, and in other ways descending to the level of street fakirs.

In , Dr. and others who are so bitterly opposed to the pretensions of the opticians have greatly weakened their own position by the notoriously superficial work they have done in this line of refraction. When teachers of ophthalmology ride such hobby horses as the ophthalmometer and impose their resultant guess work upon the public, they have small reason for criticising the opticians, or even the fakirs.

If all oculists had followed the example of their Philadelphia confrères, by doing honest refraction work with the aid of atropia and retinoscopy, the optician's pretensions would have fallen flat. Under existing circumstances, however, it looks to even a prejudiced observer as though the opticians were having the best of the argument.

Respectfully,

EDWARD J. BROWN, M.D.

Dr. Sims' Perseverance.

WEST UNION, IOWA, April 24, 1896.

To the Editor:—In the address of Dr. Jelks in our JOURNAL April 18, there is clearly a misprint. I think this should be corrected in justice to the memory of Dr. J. Marion Sims. It furnishes stronger proof of the patient perseverance of this truly great man, and evidences his wonderful power to inspire confidence in his patients, as well as all who came in close relation with him.

In the eighth line from the bottom of the first column, on page 752, the word "thirteenth" I think should read *thirtieth*. In 1876, when president of the AMERICAN MEDICAL ASSOCIATION in Philadelphia, he reported the tediousness of his efforts to perfect an operation for the cure of vesico-vaginal fistula, and remarked that the young colored woman mounted the operating table hopefully the thirtieth time. On page 52 of the "Report of Columbia Hospital for Women," by J. Harry Thompson, A.M., M.D., Government printing office, 1873, you will find the same statement, in an address delivered before the Academy of Medicine, New York, by Dr. Sims. Let Dr. Sims have all the honor—none can be too great—for his patient perseverance, and his ability to inspire hope and courage, as indicated by the fact that his patient was "placed upon the operating table the thirtieth time," instead of the thirteenth, without a murmur at "preceding failures." To any who personally knew Dr. Sims, or had met him occasionally, any matter to his credit would merit all the amplitude possible.

Fraternally, S. E. ROBINSON, M.D.

A Correction.

MINNEAPOLIS, April 19, 1896.

To the Editor:—In your report of the proceedings of the Tri-State Medical Society, in your last issue, I am so grossly misrepresented in what I said, that I must beg you to place this brief correction in your next issue.

The title of my paper was "The Relationship Existing Between Oculists and Opticians." You quote me as saying that I "advanced strong arguments in favor of licensing opticians to fit glasses." Had you said "dispense" instead of "fit," you would have expressed my sentiments. There is as much difference between dispensing and fitting glasses, as there is between dispensing and prescribing medicine; and the optician should occupy the same relation to an oculist, that a druggist does to the general and special medical practitioner, viz., a preparer and dispenser of specified remedies (glasses), upon the receipt of a physician's (oculist's) written prescription.

I claim that correcting errors of refraction is practicing medicine, and that no one should be allowed to practice any department of medicine, including refraction, unless he is a properly qualified, licensed graduate in medicine. I also advocate that as in most States, a druggist can only compound prescriptions after having obtained a pharmaceutic license, so opticians should only be allowed to dispense glasses when permitted to do so by a "State Board of Opticians" to be appointed by the governors of the different States.

Respectfully, FRANK ALLPORT, M.D.

"A Credit to America."

WINNIPEG, April 22, 1896.

The JOURNAL is improving every week—a credit to America.
Yours faithfully, M. B. FERGUSON, M.D.

Total Extirpation of the Prostate Gland and Rectum.—Salischev describes in *Wratsh* No. 2, the removal of the lower third of the rectum and the prostate gland on account of a scirrhus cancer, the fifth operation of the kind on record. The patient made a fine recovery but succumbed four months later to a meningo-myelitis. The necropsy showed that the operation wound had healed completely.—*Bulletin Medical*, April 5.

NEW INSTRUMENTS.**A COMPLETE SET OF CURETTES FOR MASTOID AND MIDDLE EAR OPERATIONS.**

BY S. S. BISHOP, M.D., OF CHICAGO.

The illustration shows six curettes and spoons conveniently arranged in the form of three instruments. They are all sharp except one that I have had left dull for work in the immediate vicinity of the facial nerve.

The smallest one is my middle ear curette. The others are the sizes and forms I have found to be the most serviceable in the mastoid operations. It is a considerable advantage to have all the curettes we require within the compass of three instruments. It saves valuable time in selecting the various instruments as we proceed, and these all having the same general appearance, the eye recognizes them at a glance. The handles are flattened and roughened so as not to slip or turn easily. They will be found useful in other operations requiring curettes. They are fine specimens of the workmanship of Truax, Greene & Co.

PUBLIC HEALTH.

Enforcement of Registration Laws in Connecticut.—The last *Bulletin* of the State Board of Health reports that steps are being taken in the State to compel physicians to make more complete returns of the births. It says: "The habitual neglect of obeying the registration laws in regard to the reporting of births, by so many physicians, has driven the authorities to take peremptory action. The Health officer of New Haven County gave a list of delinquents last month to the prosecuting attorney. The latter, in a spirit of leniency which he says will not continue, refrained from prosecuting the law-breakers, but wrote them each a warning that future complaints would be vigorously investigated and liabilities enforced. The Health officer of Fairfield County, caused the arrest of a prominent practitioner in Stamford, last month. In his case too, the court suspended judgment with an intimation that his future conduct would determine further proceedings. At a meeting of the County Health officers held in Hartford on April 4, it was voted: That in future an examination of all the certificates of births, marriages and deaths would be made and whenever a violation of the law was found, the name of the offending party will be given to the prosecuting attorney of the town in which the offence is committed. The certificates themselves are evidence, as the registrar is required to endorse on them the date of their return. In the hope of promoting more successfully the above intention, a circular letter has been prepared and sent to the physicians, setting forth the objects of the registration laws and their weighty importance to the public interest. Among other things, this circular says: 'The main purpose of the registration of vital statistics is to furnish to the public a reliable means of tracing relationship, upon which depends matters of inheritance, descent of property, pension rights, etc., and to furnish such records as will be reliable and full, years hence, when collateral sources of information have disappeared.' The circular dwells upon the importance of exactness in the statement of particulars. 'Many inaccuracies and abbreviations appear in the certificates, which at first seem to be of little importance, yet when the purpose of the record is considered, it is seen that the certificate is vitiated for the purpose for which

it is designed.' Public opinion will sustain the action of the county officers in requiring an observance of these laws."

Drainage and Sewerage of Rochester, N. Y. Dr. George W. Goler, of the Rochester Department of Health, has recently delivered before a local scientific body, an address on the sanitation of that city. He began by saying that in the earliest days natural drains, ancient watercourses, were utilized as open drains, and later to some extent served as ditch drains, along which house drainage and rainfall alike were carried to their final destination. When the city began to be laid out in streets many of these old water courses were filled up without first providing for the rainfall and surface drainage, which still found its way to and along these old levels. The result was and is to-day that dwellings built along these old natural drains are not healthful; the house cellars and walls are damp, and their inmates would be found to furnish a large number of the sick and dead of our city. At first these open ditches served the double purpose of removing rainfall and house waste, but the unsightliness of these ditches and the offensive smell led to the establishment of the covered drain or box sewer, later to the stone sewer, then in an intermediate stage to the cement pipe sewer, and lastly to the sewer of vitrified pipe, and for trunk sewers the circular or egg-shaped sewer of heavy masonry, brick or stone.

The stone cement pipe sewers were an improvement upon the old box sewers, but even they were often very imperfect. Until about 1880 the stone sewers were built square in form with plank bottoms. They were not tight and they were of shallow depth, allowing of accumulation of filth within and fouling the ground for some distance without. The cement pipe sewers were rough and imperfectly joined. Time and the action of sewage produced disintegration of the rough cement pipe through which sewage found its way to the surrounding ground, converting it into a quagmire. Added to the ditches and imperfect sewers, which daily aided in polluting the soil and air in and around our dwellings, were myriads of vaults and cesspools. Although many houses had facilities, such as they were, for disposing of sewage, all did not avail themselves of these facilities—the owners in many cases preferring to carry a drain, often of wood, back into adjacent ground or into the vault. When vault and cesspool were separate they most often consisted of a hole in the earth, sometimes boxed in with rough boards rarely tightly built of stone or brick into which a box drain emptied. These cesspools, or cesspool and vault combined, formed the common type of receptacle for house drainage and human excrement. Thousands of such vaults and cesspools dotted the city everywhere, and, to make matters worse, they were often multiplied by covering over a full vault or cesspool with earth and digging a new hole alongside of it. How many of these vaults and cesspools were formerly to be found we do not know, but we do know that at the present time, with a better system of sewers extending to nearly all parts of the city, with improved fixtures and plumbing apparatus that makes it safe to have retiring conveniences within the house, more than 15,000 vaults are in use in Rochester."

Administrative Procedures against Tuberculosis. The *Glasgow Sanitary Journal*, for February, taking for its text the recently published report of Dr. James B. Russell, the senior medical officer of health for that city and a sanitarian of international repute, discusses the subject of official measure proper to be taken for the prevention of tuberculosis.

As to particular administrative procedures, it is pointed out that, though the compulsory notification of consumption has often been discussed, it has not been anywhere adopted; that though isolation has been spoken of, it is only the last stage of consumption that is essentially dangerous, but that for such cases there should be some provision; that as to disinfection, it should always be carried out after death, and if necessary by the local authority; and that public instruction as to the precautions that are really of consequence is of much importance. Concerning tuberculous meat and milk, Dr. Russell still holds that, if an animal is affected by tuberculosis in any part of its body, the only practical way of dealing with it is to condemn the whole carcass. Here, no doubt, he would object to the practice of some of the largest municipalities on the continent where this view is not adopted, and where the meat after sterilization by heat is offered for public sale at a low rate. It is

very doubtful, however, whether meat so treated would be bought even by the poorest of the population in this country. In the report it is argued with considerable ingenuity, though not, we venture to think, with the certainty of conviction to the mind of the reader, that the decisions of the late Royal Commission are to be taken as falling in with the Glasgow system, whose enforcement was successfully fought out before the law courts in 1889. With regard to milk, however, it is not easy to object to Dr. Russell's conclusions. On this subject his deliverance is that 'the importance of taking immediate action in the direction of eliminating tuberculous cows from the dairies, first of all in Glasgow, and next from those sending milk into Glasgow, can scarcely be exaggerated. It is at least equivalent in promise of beneficial results to any part of the special action recommended in this report. . . . Science has provided in tuberculin a test which overcomes that difficulty of diagnosis of tuberculous disease in the living animal which has hitherto made professional opinion uncertain or only equivalent to suspicion, and therefore insufficient to support decisive action. This test can be systematically applied only by a specially qualified veterinary surgeon.' Very much weight is attached to the value of general hygiene in the prevention of tuberculosis, and it is pointed out that in Glasgow as a result of general sanitary progress, the mortality from phthisis has fallen in such a manner as in some continental centers and by some authorities is attributed to the special precautions regarding sputum, etc., which have within the last few years been carried out there. 'We are warranted,' says Dr. Russell, 'in asserting that among infectious diseases, tuberculosis is the most amenable of all to general hygienic measures; that, in fact, from these alone as good results are obtained as from hygienic measures plus isolation, disinfection, etc., in the case of diseases popularly known as infectious.' This statement, however, is guarded as follows: 'It is not implied that special measures directed against the infectivity might not have produced even better results; but in view of what has been accomplished, and in view of the difficulties in the way of special prophylaxis, it is contended that more is to be expected from general hygiene.' In parallel columns Dr. Russell quotes from Dr. Thorne Thorne a specification for building a dwelling-house which will promote, and another dwelling-house which will prevent consumption. The former is to have a soil cold and damp or subject to the influence of the rise and fall of subsoil water; the walls are to be liable to dampness; the surroundings are to be such as to prevent the free movement of air and the ample exposure to sunlight; the building is to have such structural defects as will prevent ventilation by night and day and the entrance of daylight into the habitable rooms. The other dwelling-house is to have provisions in all respects the reverse of this."

Bovine Tuberculosis.—To the Editor:—I enclose herewith copy of a letter which I am sending to the medical directors of leading life insurance companies and to the editors of the principal medical journals.

I hope that the importance of the subject will entitle it to space in the columns of the *JOURNAL OF THE ASSOCIATION* and that you will assist in securing such a discussion of the subject as shall result in a diminished death rate.

Respectfully yours, HOWARD CARTER, M.D.

Milk Inspector's Office, St. Louis, April 20, 1896.

To the Chief Medical Directors of Life Insurance Companies:

Gentlemen: We are convinced that the great prevalence of tuberculosis among dairy cattle and the transmission of infection to human beings through the meat and especially through the milk of such animals is not second in importance to any question confronting the intelligent medical men of the day. I have demonstrated the presence of bacillus tuberculosis not only in the lesions and pus but in the milk of cows apparently healthy which reacted to the tuberculin test, establishing the identity of bovine with human tuberculosis and confirming the examinations reported by Drs. Salmon, and Smith of the U. S. Department of Agriculture, and others. I am not aware that this aspect of the subject has been at any time brought to the attention of life insurance companies. Its direct bearing upon the public health and consequently upon the death rate should specially commend it to them as a problem the practical solution of which would result in a saving of thousands of human lives and of millions of dollars annually. Not only would the death rate be reduced, but an improved vitality would be developed in coming generations by avoidance of the entry into the system of toxic germs, which, if they do not directly lead to conditions resulting in death may lie dormant until the general

vitality is sufficiently lowered to permit their full development. In bringing this matter to your attention I desire to request an energetic and persistent demand from the medical profession in general and from the directors of life insurance companies in particular for the enactment in all States of protective legislation, protection that will protect and benefit our whole people and diminish the ravages of this most insidious and dreaded enemy of the human race.

Very respectfully, HOWARD CARTER, M.D.
Milk Inspector, St. Louis.

Health Circular No. I.—The State Health Officer of Indiana has issued the following circular, concerning how certain foods shall be protected from dust pollution.

In many cities and towns it is the custom for grocers, butchers and other venders of food, to expose their wares in front of their shops and stores. Butchers very frequently make an unusual exposure of meats to the dust and filth of the street. Grocers expose on the sidewalks in front of their stores, dried fruits, smoked meats, etc.

Objections: The dust that floats in the air contains a great deal of filth. It carries pulverized manure, dried catarrhal and consumptive sputum, and much other offensive matter, besides microorganisms of all kinds. All this we must endure, to the evident disadvantage of our health, when we walk abroad in cities where dust is not kept down. It is not well, however, that we should eat dried manure and dried spittle on our meat and groceries, even if cooked.

What to Do: County Health Officers are hereby directed to issue written orders to all butchers and venders of meats not to expose outside their shops carcasses or parts of carcasses, of any animal intended for food. Neither shall dressed meats be transported through the streets without being protected from dust. Grocers must be ordered not to expose dressed poultry, nor uncovered smoked meats, nor uncovered dried fruits as dried apples, dried peaches, currants, etc., nor indeed any foods which may become polluted and corrupted by dust from the air in the way above described.

The Law: Section 2069 R. S. 1881 gives ample power to Health officers in this matter.

J. N. HURTY,
State Health Officer.

BOOK NOTICES.

I. King's College Hospital Reports, being the annual report of King's College Hospital and the Medical Department of King's College. Edited by NESTOR TIRARD, M.D., F.R.C.P., W. WATSON CHEYNE, F.R.C.S., F.R.S., JOHN PHILLIPS, M.A., M.D., F.R.C.P., W. D. HALLIBURTON, M.D., F.R.S. Vol. II. London: Printed by Adlard & Son, 1896. 8vo, cl., pp. 376.

II. St. Thomas' Hospital Reports. New series. Edited by Dr. T. D. ACKLAND and Mr. BERNARD PITTS. London, 1896. 8vo, cl.

III. Medical and Surgical Report of the Presbyterian Hospital, in the City of New York, vol. I, January, 1896. Edited by ANDREW J. MCCOSH, M.D., and WALTER B. JAMES, 8vo, bds., pp. 256.

I. This volume will not only be of interest to all old King's College men on account of its annual statements, but as well to all clinicians. The "Notes on Cases of Interest," by Prof. Rose, Prof. Cheyne, Mr. Careless, Mr. Burghard and Mr. Beale, are worthy of careful study. The reports from the various departments are unusually full and complete. The original papers by Dr. Tirard, Dr. Dalton, Sir Hugh Beevor, Mr. Cheatle, Dr. Short and Dr. Hewlett are valuable contributions to medical literature.

II. This is volume XXIII of the St. Thomas reports. It contains some very interesting papers by Drs. Cory, Payne, Sherrington and Cullingsworth, Mr. Battle, Mr. Stabb, Mr. Makins, Mr. Pitts, Dr. Ackland and Mr. Ballance. The paper by Mr. Pitts on umbilical hernia is alone worth the price of the volume, and the elaborate study of cerebellar abscess by Ackland and Ballance will make this series much sought after.

III. This is the first medical and surgical report of this hospital and we naturally turn to it with some curiosity. An examination of the work shows that this hospital has nothing to fear in comparison with the foreign hospital reports. There is no padding, but on the contrary concise and well-written accounts of interesting cases. The work done at this hospital,

as set forth in this volume, is a credit to American medicine and surgery.

The Non-Heridity of Inebriety. By LESLIE E. KEELEY, M.D., LL.D. Chicago: S. C. Griggs & Co., 1896. 8vo, cl., pp. 359.

"Oh! that mine enemy would write a book," said Job. He might then have some basis to fight on and penetrate the designs of his persecutor. Dr. Keeley has now done what Job wished his enemy to do, and those who can read between the lines can easily see that his grievance, that of non-recognition by the profession, dominates the whole book. He ostensibly believes in the non-heridity and curability of inebriety. He thinks he is dreadfully severe in his criticism of the regular profession: in reality he is only exhibiting his sore spots. He starts out to discuss an alleged disease, but he discusses medical ethics more. Thus (page 14): "The pretense of 'regular medicine' is that all dogmas are rejected: but the meaning is that all new things are rejected." This statement is so absolutely false that any drug manufacturer, any drug importer, any dispensing pharmacist could tell Dr. Keeley that on the contrary the new things are sought after with eagerness.

Again (page 15): "The germ theory was ridiculed for fifteen years, while its defenders were ranked as 'quacks.' Electricity, hydrotherapy, massage, all were classed in their beginning as quackery. But the 'grand old profession' generally ends by adopting everything. It will some day, if its morals improve, adopt all the pathies, including Christian science. It will fight the question many years, possibly, but will some day incorporate into the code of ethics a provision which will give a physician a proprietary right to his inventions relating to surgical instruments and remedies." *Hinc illæ lachrymæ.* We shall indeed come to a pretty pass when we acknowledge with due humility Dr. Blank's patent cure for meningitis; Dr. Scovendyke's proprietary cure for cancer; Dr. Winkenpoop's own dose for folly, as well as Dr. Keeley's secret cure for inebriety. No, Dr. Keeley: come out with your formula, let us have something tangible, and then we can discuss it and adopt it if it seems wise; until then there is nothing to discuss, and as the book gives no information on that point, we end where we began.

The Toxic Amblyopias: Their Symptoms, Pathology and Treatment.

By GEORGE E. DE SCHWEINITZ, M.D., Clinical Professor of Ophthalmology, Jefferson Medical College of Philadelphia. Very handsome octavo, 240 pages, 41 engravings and 9 full-page colored plates. Limited edition. De luxe binding, \$4.00, net. Lea Brothers & Co., publishers, Philadelphia and New York. 1896.

The task of the reviewer is a very pleasant one if there is so much to praise and so little to criticize as in the book before us. A careful examination has convinced us that the author has overlooked nothing that has ever been published on toxic amblyopias. The book is an excellent summary of our present knowledge of toxic amblyopias and a complete dictionary of the literature on this subject up to the present time, and will prove a veritable gold mine of reference for future writers. Tobacco and alcohol amblyopia naturally receive the greatest attention, occupying almost one-half of the book; quinin amblyopia comes next in importance, and here the author's original experiments and microscopic investigations are of especial interest. The remaining space of the book is devoted to abstracts of the clinical reports on visual disturbances caused by arsenic, lead, opium, salicylates, iodoform and a large number of other drugs and toxic agents. The book is printed in clear, large type, on excellent paper and issued in a very pleasing dress of cream and gold.

New Truths in Ophthalmology, as developed by G. C. SAVAGE, M.D. Third edition.

In the third edition of this work the accomplished author has not attempted to advance any "new truths," but has added three new chapters in attempting to prove those already advanced. One of these is devoted to a reply to Dr. Hotz's

criticism on his theories of the action of the oblique muscles. The incorporation of such an article in a book without giving the original criticism to which it is a reply, seems hardly to be in a spirit of fairness. Another chapter is given to an article published in the *Ophthalmic Record*, by Dr. Lowry, on the "Obliquity of Retinal Images in Oblique Astigmatism as Shown by Photography." The third is given to the author's address before the Eighth International Congress of Ophthalmology, without discussing the truth or falsity of the author's "truths." It is greatly to be regretted that he has not presented them in better form, avoiding the repetition and incongruity of a collection of papers and addresses on the same theories written at different stages of their development. The book is otherwise well written and contains a great deal of useful information.

NECROLOGY.

WILLIAM HUNT, M.D., for many years senior member of the surgical staff of the Pennsylvania Hospital, died on the 17th inst., in Philadelphia, of debility after several years of invalidism, following a severe injury received some years ago by being knocked down and run over by a wagon while crossing the street. It was believed in addition to fracture of ribs and other injuries, that he sustained a fracture of the cervical vertebrae. He had symptoms of concussion of the brain and for a long time was confined to the house and in fact never regained his health. Dr. Hunt was born in Philadelphia Sept. 26, 1825, and was educated in the Friends' School. He studied medicine in the office of Dr. George B. Wood, and was graduated by the Medical Department of the University of Pennsylvania in 1849. He entered the Pennsylvania Hospital as Resident Physician and served for two years. In 1854 he became demonstrator of anatomy in the University of Pennsylvania, and held this position for ten years. In 1856, he became a member of the surgical staff of the Episcopal Hospital and in 1863 was elected to the same position in the Pennsylvania Hospital, the former institution he served for twelve years and the latter for thirty years. He was also for a period surgeon to the Wills Hospital and to the Orthopedic Hospital. During the war Dr. Hunt was one of the Acting Assistant Surgeons of the United States Army, and was several times ordered to the front for active field duty. His principal military service, however, was in the government hospitals in Philadelphia. He served until the end of hostilities, but during all this period he refused to wear a uniform on account of his religious connection. He was a Fellow of the College of Physicians from 1854 to his death, and was for many years one of its Censors and a member of some of its most important committees. He was also a member of the County Medical Society, and of the Academy of Surgery (having been elected President of the latter) and an honorary member of the American Surgical Association. He joined the AMERICAN MEDICAL ASSOCIATION in 1859. Dr. Hunt's writings were eminently practical and his contributions to medical journals were always gladly received by the editors and readers. He was one of the authors of "Surgery in the Pennsylvania Hospital," and an associate editor of the *Annals of the Universal Medical Sciences*.

N. S. HILL, M.D., died at his residence in Neville, Ohio, April 13, where he has practiced consecutively for thirty years. He graduated from the Medical College of Ohio in 1862, was mustered assistant surgeon 121st O. V. I., Sept. 11, 1862, and served with that regiment until Oct. 28, 1864, when he was promoted Major Surgeon 52d O. V. I., and served as such to the close of the war. His army service included Gen. Sherman's Atlanta campaign and "March to the Sea." He was an active member of the Clermont County Medical Society, the Ohio State Medical Society and the AMERICAN MEDICAL ASSOCIATION. He was a prominent mason, Odd Fellow and member

of the Grand Army of the Republic. He was for several years a sufferer from chronic interstitial nephritis, the immediate cause of death being ascribed to a mitral insufficiency. At his request he was cremated and his ashes interred in Spring Grove.

MOSES WADLEIGH RUSSELL, M.D., died at Concord, N. H., on April 18, aged 59 years. He was born in Sutton, N. H., studied at the Colby Academy, New London, same State, and under Dr. Dimon Davis began the study of medicine about 1860, taking his medical degree from Dartmouth College in 1863. During the following four years he attended the special courses of instruction at New York under Dr. Austin Flint and at the College of Physicians and Surgeons. He practiced for a few years at Sutton, going thence to Concord, in 1867 or 1868. He was a member of the representative medical societies of his locality, and in 1892 was president of the State Medical Society.

JAMES JAY MAPES, M.D., of New York city, died April 10, at Saranac Lake, aged 31 years. He was a son of Charles V. Mapes, and a great-grandson of Gen. James Jonas Mapes, who commanded the American forces about New York city in the War of 1812. He was a nephew of Mrs. Mary Mapes Dodge. He was an A.B. of Columbia College in the class of 1888 and a graduate of the College of Physicians and Surgeons in 1891; he became an interne of New York Hospital, and after returning from an educational trip to Europe took an internship at the Nursery and Child's Hospital. Dr. Mapes studied under Dr. Roux, in Paris, and when the discovery of the antitoxin treatment for the cure of diphtheria was made he brought the first vials of the fluid to this country. His health broke down six months ago, and he developed tuberculosis.

LEON DIDELOT, M.D., at Lyons, at the early age of 46. His name is familiar on account of his many scientific writings, showing his mastery of medicine, chemistry, geology, paleontology, archeology, mineralogy and physics.

GEORGE WIEBER, M.D., was born April 15, 1825, at Weitzler, Germany. His father was a Lutheran clergyman who realized the value of a liberal education and gave his son the advantage of his experience. Dr. Wieber pursued his study of medicine in Halle, Marburg and Giessen; and in 1848 entered the German army as surgeon, continuing his service during the short war with Denmark. After leaving the army he served as surgeon on an American clipper for several years. In 1857 he began private practice in a suburb of Brooklyn. He gained the confidence and respect of the medical profession in those early days. At the outbreak of the Rebellion, he entered the service as Surgeon of the German Battery, afterward a part of the First N. Y. Artillery. While Surgeon Wieber was stationed with his battery at White-House Landing (on the Pamunky river), Va., in May, 1862, the writer had occasion to accept of his hospitality; for after superintending the transportation of the sick and wounded from the front to the Landing one stormy day and night, he was wet, weary and hungry, and Surgeon Wieber sheltered, warmed and fed him. It was but one of many offices of kindness he delighted to perform.

Dr. Wieber served in other positions as medical officer to the army, after the reorganization of the Artillery, till he returned to private practice in Brooklyn. Although an able practitioner in good standing for so many years, Dr. Wieber was not legally qualified under the existing laws of New York State. He therefore submitted to an examination by the Board of Censors, in 1875, and was granted a license by the Kings County Medical Society. He continued the practice of medicine in Brooklyn until prevented by sickness, his practice being more laborious and humane than lucrative. In 1890 he received an unusual injury by a fall, rupturing the rectus femoris muscle of the right thigh, which crippled him for several months. He was a member of Dakin Post, G. A. R. He served as sanitary inspector to the Brooklyn Board of Health for five years. He was formerly a member of Kings County

Medical Society and of the Anatomical and Surgical Society. At the time of his death he was a member of the New York German Medical Society, an original Fellow of the New York State Medical Association, an original Fellow of the Kings County Medical Association and one of its Executive Committee from 1887 to 1892. Dr. Wieber's first wife did not survive long after the birth of her only child. His second wife to whom he was married on Feb. 10, 1863, was the widow of the late Dr. Haller. Two children, twin boys, died of diphtheria and scarlatina in February, 1873.

Dr. Wieber was taken sick on Dec. 15, 1895, with an obscure intestinal trouble which proved to be carcinoma of the mesentery, and died at his home Jan. 31, 1896, hemorrhage of bowels supervening. A year or more before his death, he delivered sealed instructions to his wife regarding the disposition of his remains, which were as follows, namely: "Dakin Post is to be notified at once to take charge of the funeral. The services are to be held in my residence, and to consist simply of the Grand Army ritual. I direct that my remains be taken to the crematory, and there incinerated, the ashes then to be interred in the graves of my two children, buried in Evergreen Cemetery." His instructions were complied with. His widow and daughter, Mrs. Schoonmaker, survive him, also his son Adolph, who graduated in medicine at Giessen, Germany, in 1889, and at Long Island Hospital in 1890.

The many friends and patrons of Dr. Wieber miss him and mourn their loss. The medical profession of Brooklyn has lost a zealous supporter of the principles which pertain to the highest type of its science, art and ethics. The Kings County Medical Association assures the family of its sympathy, and that it will retain pleasant recollections of its deceased Fellow.

ASSOCIATION NEWS.

Notice.—Members contemplating attending the Atlanta meeting will please bring their receipts for dues of 1896 and thereby save second payment. Very truly yours,

CHICAGO, April 23, 1896.

H. P. NEWMAN.

Notice to the Ophthalmological Section.—The Section dinner will be held at the Aragon Hotel, Atlanta, Tuesday evening, May 5, at 8:30 P.M. The charge will be \$2 a plate, and it is hoped that ladies will attend. The dinner is in the hands of Dr. Dunbar Roy, "The Grand," Atlanta, Ga. All desiring to attend will please communicate with him at once, that he may have some idea as to the number for which to provide. It is hoped that the attendance will be large.

FRANK ALLPORT, M.D., Secretary.

MINNEAPOLIS, April 21, 1896.

Section on Diseases of Children.

A. C. COTTON, Chairman, Chicago, Ill.

A. J. WORK, Secretary, Elkhart, Ind.

Executive Committee—C. G. JENNINGS, Detroit, Mich.; W. S. CHRISTOPHER, Chicago; E. H. SMALL, Pittsburg.

TUESDAY, MAY 5TH—AFTERNOON SESSION.

1. ADDRESS OF CHAIRMAN. A. C. COTTON, Chicago.

2. Functional Dyspepsia in Children,

J. M. G. CARTER, Waukegan, Ill.

3. Diagnosis in Diseases of Children,

C. G. SLAGLE, Minneapolis.

4. Pediatric Therapeutics as Proven by Experience.

J. A. LARRABEE, Louisville.

5. Children of Feeble Resistance—Their Care and Management,

JOHN MADISON TAYLOR, Philadelphia.

6. Fractures in the Shafts of Bone in Children,

THOMAS H. MANLEY, New York.

Discussion opened by T. M. ROTCH, Boston; WM. PEPPER, Philadelphia; D. W. GRAHAM, Chicago; EDWARD H. SMALL, Pittsburg; I. N. LOVE, St. Louis; J. A. HOFHEIMER, New York.

WEDNESDAY, MAY 6TH—MORNING SESSION.

7. An Experience with Antitoxin with Instructive Results,

JOSEPH WM. STICKLER, Orange, N. J.

8. The Fallacy of Antitoxin as a Cure for Diphtheria.

ELMER LEE, Chicago.

9. Some Practical Points on the Effects of Antitoxin and Intubation with Especial Reference to Infant Feeding in Malignant Diphtheria, LOUIS FISCHER, New York.

10. Diphtheritic Laryngitis,

A. CAMPBELL WHITE, New York.

11. Sepsis in the Newly Born,

HENRY TULEY, Louisville.

12. Erysipelas in Infants,

ELLA PATTON, Quincy, Ill.

Discussion opened by PROF. EDWIN KLEBS, late of Zurich;

E. F. INGALS, Chicago; J. H. MCCOLLUM, Boston; W. E.

CASSELBERRY, Chicago; J. A. LARRABEE, Louisville; JAMES B.

HERRICK, Chicago; W. B. PARKS, Atlanta; W. D. BOOKER,

Baltimore; CHARLES JEWETT, Brooklyn, N. Y.; J. C. HOAG,

Chicago.

WEDNESDAY, MAY 6TH—AFTERNOON SESSION.

13. Chorea,

HENRY HATCH, Quincy, Ill.

14. Pertussis as a Neurosis,

S. J. RADCLIFFE, Washington.

15. Treatment of Infantile Spinal Paralysis,

HAROLD N. MOYER, Chicago.

16. Petit Mal in Children,

LOUIS BISHOP, New York.

17. Observations in Cases of Epilepsy following Injuries to the Head in Infancy, Childhood and Early Youth,

W. A. DIXON, Ripley, Ohio.

18. Spinal Injuries in Infants,

JAMES PORTER FISKE, New York.

Discussion opened by D. R. BROWER, Chicago; WM. OSLER,

Baltimore; SAMUEL WOODY, Louisville; J. C. WILSON, Phila-

delphia; WM. E. WIRT, Cleveland; SANGER BROWN, Chicago.

THURSDAY, MAY 7TH—MORNING SESSION.

19. Enterocolitis,

DANIEL H. CUNNINGHAM, Chicago.

20. Intussusception,

FRANK GIBSON, Pittsburg.

21. Use of Stomach and Rectal Tubes in Gastro-Intestinal Diseases of Children,

W. JAY BELL, Atlanta.

22. The Use of Physostigma Venenosum in Cholera Infantum and Cerebro-Spinal Congestions,

J. SCHNECK, Mt. Carmel, Ill.

23. To be announced,

JOHN E. WOODBRIDGE, Cleveland.

24. Typhoid Fever in Children,

JOHN A. ROBINSON, Chicago.

Discussion opened by W. B. PARKS, Atlanta; E. P. BRUSH, Mt. Vernon, N. Y.; J. M. G. CARTER, Waukegan, Ill.; W. D. BOOKER, Baltimore; W. JAY BELL, Atlanta; LOUIS FISCHER, New York; ELMER LEE, Chicago.

THURSDAY, MAY 7TH—AFTERNOON SESSION.

25. Curvatures of the Spine Occurring in Small Children,

WILLIAM E. WIRT, Cleveland.

26. Children's Shoes: Injurious Effects,

MERRILL RICKETTS, Cincinnati.

27. Rachitic Deformities and their Treatment,

JOHN RIDLON, Chicago.

28. Rachitic Chest Deformity in Twins, with Exhibition of Casts,

W. J. BELL, Atlanta.

29. Circumcision is not Necessary in Young Children,

W. B. PARKS, Atlanta.

FRIDAY, MAY 8TH—MORNING SESSION.

30. The Evolution of Girls,

HARRIET E. GARRISON, Dixon, Ill.

31. High Pressure Process of Teaching in our Public Schools, considered from a Medical Standpoint,

W. H. SHORT, La Grange, Ind.

32. To be announced,

I. N. LOVE, St. Louis.

33. Retention of Urine in the Newly Born,

EDWARD H. SMALL, Pittsburg.

34. Infantile Scorbutus,

ALBERT H. BURR, Chicago.

35. Rheumatism,

SAMUEL E. WOODY, Louisville.

36. Rheumatism in Children,

J. A. HOFHEIMER, New York.

Discussions opened by WM. OSLER, Baltimore; WM. PEPPER, Philadelphia; WM. E. QUINE, Chicago; J. A. WORK, Elkhart, Ind.; SARAH HACKETT STEVENSON, Chicago; G. W. MCNEIL, Pittsburg; JAMES B. HERRICK, Chicago.

SOCIETY NEWS.

The Roentgen Rays as an Aid to Surgical Diagnosis.—At the last meeting of the Academy of Surgery, held April 6, Dr. Thomas G. Morton, Philadelphia, read a brief "Note of a case in which a pistol bullet imbedded in the shaft of the radius was located by the X rays and successfully removed by operation based upon the skiagraphic aid to diagnosis." The history of the case was as follows:

William L., aged 30 years, of dark skin, probably a Mexican native or a mulatto, was brought to the Pennsylvania Hospital, Feb. 28, 1896, suffering with a recent pistol shot wound of the

right forearm, received in the act of running from an officer. Upon examining the limb it was ascertained that the ball had entered on the outer side, just below the elbow, and had apparently passed in a downward direction, but all efforts to locate the missile definitely were unsuccessful, not only upon this occasion, but also in subsequent attempts while in the hospital. Two weeks later, by order of the court, the patient was sent to the county prison, where Dr. Morton again saw him, with Dr. B. F. Butcher. At this time the wound was still open and discharging moderately; radius motion was painful and greatly restricted. There was no evidence of transverse fracture of either bone of the forearm. On account of the local symptoms and the forearm being very large and muscular, he decided not to make any immediate search for the ball, which was causing considerable irritation, but to first locate, if possible, the ball by means of the X rays. Through the kindness of Professor Goodspeed, of the University of Pennsylvania, he was able to accomplish this. As the result of several exposures, none being over five minutes, three skiagraphs were made, which were exhibited. Professor Goodspeed sent the following report: "Experiment eminently successful. Radius is split two and one-half inches. Bullet located four and one-half inches from the elbow joint when the arm is flexed inside."

Acting upon the information thus given on the following day, March 27, Dr. Morton made an incision directly over the location thus revealed, and discovered the ball lying partly imbedded in the radius, under a splinter of bone which roofed it over as is shown in one of the skiagraphs. Having found the location of the ball it was extracted without difficulty. It was observed, after removing the ball, that it had penetrated so deeply that an opening was made directly through the shaft of the radius and a portion of the upper surface had become separated and overlaid the missile, which accounted for the previous failures to find it by the usual means. This appears to be the first case in this city in which the Roentgen rays have settled an otherwise unsolvable problem of surgical diagnosis and have lead directly to operation for the relief of the condition.

Experiments by Professor Goodspeed and Dr. Cattell, at the University of Pennsylvania, Department of Physics, have been successful in very materially reducing the time needed for exposure to the rays and the production of skiagraphs, one being recently obtained of a human foot covered by stocking and boot, which showed the articulations and bones very clearly, and in which the time of exposure was only one minute.

To Prevent the Spread of Tuberculosis. The St. Louis Medical Association, March 7, 1896, passed the following:

WHEREAS, It is established on a firm basis that tuberculosis is communicable under certain conditions, and that the pulmonary forms are the most prolific sources of external dissemination of the germs of the disease; and

WHEREAS, The health boards of this country and other countries are urgently pressing the legislative authorities to affirm by enactment that pulmonary tuberculosis is transmissible and should be dealt with accordingly; and,

WHEREAS, The State Board of Health of Missouri in a committee report made to this body last year, recognized the infectious nature of this malady; and,

WHEREAS, It is urgent that the public should realize fully the nature of this plague which destroys fully one sixth of the population, and that the people should be protected from infection;

Resolved, That the president of the St. Louis Medical Society appoint a committee to include some members of the State and city boards of health to draft a measure for the prevention of the dissemination of consumption in the street cars, public schools, churches, theaters and other public places, and to advocate its passage by the city legislators if compatible with the constitution and scheme of charter, and by the State in the near future.

Committee: Drs. Paquin, Bremer, Ravold, Mulhall, Hughes.

Wayne County Medical Society. The Wayne County (Mich.) Medical Society passed the following resolutions April 23, 1896:

WHEREAS, An organized effort is now being made in the District of Columbia and State of Massachusetts to secure the enactment of laws for the restriction of experiments upon the lower animals; and

WHEREAS, Without such experiments there could be no scientific biology and medicine would have no scientific basis; and

WHEREAS, Our knowledge of physiology and toxicology and the action of many important medicinal agents has been gained in this way; and

WHEREAS, Our precise knowledge of the etiology of a considerable number of infective diseases has been obtained by inoculating susceptible animals with pure cultures of the various pathogenic bacteria, and could have been obtained in no other way; and

WHEREAS, By such experiment the demonstration has been made of the specific pathogenic power of the anthrax bacillus, the tubercle bacillus, the diphtheria bacillus and many others; and

WHEREAS, Many of our life-saving surgical operations have only become possible by experimentation upon the lower animals; and

WHEREAS, It would be impossible in the face of such legislation as is contemplated; be it therefore

Resolved, That the Wayne County Medical Society, of Detroit, Mich., do most earnestly protest against the enactment of such proposed legislation, believing it highly inimical to the advancement of science, and opposed to the best interests of suffering humanity; and be it further

Resolved, That a copy of these resolutions be sent to the Hon. John W. Babcock, of Wisconsin, to the members of Congress at Washington from our State, and also the members of the health committee of the Assembly and Senate of the State of Massachusetts.

MISCELLANY.

The Wonderful Ray.—Apropos of the wonderful penetrating powers of the cathodic ray, a young lady, at a recent dinner party in New York, ventured the remark that she understood that these new cathartic rays could go through anything.

Dr. S. D. Mason, of Brooklyn, N. Y., has resigned from the position of consulting physician at Inebriates' Home, Kings County, N. Y. He has been thirty years consultant in this asylum, and associated with it from its first organization.

An International Periodical, devoted to the history and geography of medicine, is soon to be published in Amsterdam, by Dr. Peypers, Parkweg. The articles will appear in English, French and German. Many scientists have already promised their coöperation, among them several Americans.

Whooping Cough Bacillus. Kourlov has been investigating the saliva of whooping cough patients, and has found in every case and in them alone, a certain special, spore-forming, ciliated ameba, which he suggests may be the cause of the disease.—*Bulletin Médical*.

Disputed Claim for Priority.—The *Deutsche Med. Wochenschrift* of April 9, is the battle ground of a lively tilt between Gruber of Vienna and Pfeiffer of Berlin, each claiming to have announced first the peculiar behavior of the bacteria of cholera and typhoid fever as they roll up into balls and flakes, in presence of the immunizing serum, and the differential value of this fact.

Honor Medal for an Assistant Surgeon.—President Cleveland has awarded a medal of honor to Jacob F. Raub. He was assistant surgeon in the 210th Pennsylvania Volunteers, and at the battle of Hatcher's Run, Va., Feb. 5, 1865, discovered a flank movement of the Confederate forces, apprised the commanding general at great peril, and, though a non-combatant, voluntarily participated in repelling the attack.

Traumatism and Tuberculosis. The general discussion as to the contagiousness of tuberculosis has led to the publishing of many cases of tuberculosis following an accident to the lungs in perfectly healthy persons. Some ascribe it to the locus minoris resistentiae, and others believe it is caused by con-

tagion in the hospitals where the traumatic cases are carried for treatment, while Kelsch asserts that it is due to auto-intoxication from some latent, unsuspected tuberculous lesions, which he states are found in two-thirds of the necropsies of young and old alike, who die from any cause, athrepsia excepted.

Is the Husband's Consent to an Operation Indispensable?—The *St. Petersburg Med. Wocheenschrift* of April 4, is devoted to a discussion of the question whether a physician does right to yield to the husband's refusal to consent to an absolutely necessary operation on his wife or child. Russian physicians are collecting data of cases thus sacrificed to the general custom of deferring to the will of the man of the house, on which to found an appeal to the government for an extension of the rights and duties of the attending physician. A case has just been decided in Brussels, bearing upon this point. A couple of prominent surgeons were sued by the husband of a woman who had died after an operation, unauthorized by him, or, as he claims, by his wife. The verdict was in favor of the surgeons. —*Gaz. Méd. de Liège*, April 9.

Contract to Retire from Practice.—A physician and surgeon sold his practice for \$250 and stated in the contract that he would withdraw and retire from the practice of his profession at a certain time, adding: "In short, I have decided to permanently withdraw and retire from the practice of medicine in Texarkana and vicinity, and it is my intention to introduce and establish the above-named doctors, W— and R—, as my successors to my practice and good will among my clientele." This last clause, the supreme court of Arkansas construes, *Webster v. Williams*, Feb. 22, 1896, in connection with the testimony of several witnesses that the doctor had declared that he had contracted to permanently retire, as a contract for permanent retirement. It also holds that the contract was reasonable and valid, and that the complainants were entitled to a perpetual injunction in accordance therewith.

While the Editor Slept.—The editor of the *General Practitioner* freely acknowledges that he fell into a pit dug for him by a Cincinnati Colleague. He appears to have mistaken Dr. Samuel Johnson, the long deceased lexicographer for some other Dr. Johnson now alive in the Western Reserve. He makes his odd confession thus: "Our article in the January number, reprinted from the *Cincinnati Medical Journal*, on 'Marriage and Celibacy,' turns out to be from the pen of Dr. Samuel Johnson in *Rasselas*, written so long ago that it might have rested in an Egyptian sarcophagus. We know a good thing when we see it, and we humbly apologize to our readers for not having seen this particular good thing a long time ago. We wondered who it was who wrote Johnsonese in 1895, but we were perfectly innocent, we confess, of ever having read the article."

Scientific Instruments and the Tariff.—The United States circuit court of appeals holds, in the case of *United States v. Presbyterian Hospital*, decided Jan. 16, 1896, that it does not follow that because articles are made for the use of physicians and surgeons in the practice of their profession that they are scientific instruments within the meaning of the term as used in the tariff law. The court says that the term "scientific instrument" does not describe one appertaining to any particular vocation or profession. It suggests an instrument which is something other than a mere mechanical tool or appliance, however peculiarly adapted to use it may be in scientific labors; one which, because it embodies some scientific conception, would attract the interest of learned minds; something as distinct from the ordinary mechanical instrument as is the scientific toy from ordinary toys. What is or is not such an instrument, in cases arising under the statute, is to be determined as a question of fact, according to the nature of the thing itself, and not necessarily according to the nature of the use for which it is primarily designed or in which it is prin-

pally employed. Ordinary metal tubes, a wire mask covered with flannel, and glass tubes for holding wound catgut, imported for use in clinics and training schools the court does not consider attain to the dignity of "scientific instruments."

New Hospitals for St. Louis.—The St. Louis City Council recently passed a bill which provides that the City Comptroller shall set aside 1 per cent. of the taxes each year for the purpose of erecting a new city hospital building. The amount required to build such a structure as is demanded, will be \$2,000,000. Hence the above provision, which would yield at most about \$75,000, would be inadequate. By private benefaction, a hospital for women may presently be inaugurated, a St. Louis lady having given \$100,000 as an endowment fund for an institution to be located on Henrietta street and Grand Avenue, and has also contributed \$40,000 in cash, with which to erect the buildings and purchase the grounds. The plans provide for thirty private rooms and all modern conveniences, and all appliances, both medical and surgical. Josephine Hospital (after the given name of the lady endowing the same) will be one of the best equipped and best managed institutions in the city. Dr. F. J. Lutz is chief surgeon, and the buildings are being erected under his supervision.

Proposed Jennerian Society in England.—The *British Medical Journal* states that the friends of vaccination in an antivaccination territory are about to take aggressive and organized action. The existing prevalence of smallpox in Gloucester, besides occurring in a city which is notoriously a center of antivaccinationism, has occurred in a city in which also there are not a few able exponents of the beneficent qualities of vaccination. "Of these latter, one, Dr. Bond, the medical officer of health of the Gloucestershire combination of sanitary areas, has recently issued papers from his own pen with a view of instructing the people in their own interest as to the facts concerning the benefits to be derived from vaccination and revaccination. Not only so, but Dr. Bond has also started a movement under the title of the 'Jenner Society,' for securing a wider dissemination of the literature regarding the prophylactic powers of vaccination, so that persons who at present know only the onesided arguments of antivaccination agitators may be in possession of the abounding evidence in favor of vaccination. There are other proposed lines of action to be taken by the society, not alone in Gloucestershire, but as widely as its membership shall extend: these, however, we do not touch upon here. Suffice it for the moment to state that any movement which has for its main object the dissemination of terse, simple and well-digested data and facts showing the beneficent results accruing from vaccination will be sure to confer an important service on the nation."

Privileged Observations of Physicians.—In a bastardy case it was proposed to prove by a physician that the mother had called on him in his office, accompanied by a young man of a particular description, which distinguished the latter from the one sued, and that the two said they were husband and wife, and wanted an examination made to see if she was with child. All of this, relating to matters which the physician had learned while the woman had called upon him in his professional capacity, the appellate court of Indiana holds, *Post v. State*, Feb. 21, 1896, was privileged. Not only was the physician prevented from revealing anything told him by the woman, but it would be equally objectionable, the court says, for him to divulge matters he had learned from mere observation. What he observed as to who accompanied the woman and what they said, must have been in reference to the subject-matter of the examination—the purpose for which they had called upon the physician—and was therefore privileged. The court also holds that there was no error in a refusal to allow another physician to testify that the child was perfectly developed, declaring that this information was also clearly privileged.

Antitoxin Treatment of Pseudo-Membranous Angina.—Dr. George Blumer reports in the *Bulletin* of the Johns Hopkins Hospital a series of eighteen cases of angina with generally successful results under the serum treatment. One of his cases is interesting from a bacteriologic point of view, for, so far as we have been able to make out, a membranous angina due to the bacillus pyocyaneus has not been described hitherto. This organism, though usually comparatively harmless, has been described as a factor in various diseased conditions, usually in association with other organs: in our case it was apparently in pure culture, but this may be due to the fact that it had overgrown the organisms with which it was associated.

The comparatively frequent presence of the pyocyaneus in chronic otitis media would lead one to suspect that it may not be an infrequent inhabitant of the nasal or buccal cavities. "Of the eighteen cases above recorded, sixteen received the antitoxin treatment, three of these cases being non-diphtheritic. While this of course is too small a number of cases on which to base any statistical conclusions, several facts in connection with the treatment seem worthy of attention. Two of the cases died, but both of these were moribund on admission, one dying three and the other eight hours after admission, so that the antitoxin was given no chance. The other thirteen diphtheria cases were most of them mild, in fact none were very severe, but both on the general condition and on the temperature the antitoxin seemed to have a marked effect. It was almost invariably noticed that the day following the injection the patient was much brighter, and in the case of children the return of the appetite was the most marked indication of improvement. In looking over the cases it will be noted that in those due to the bacillus diphtheriae the antitoxin, as a rule, caused a reduction of the temperature to the normal inside of twenty-four hours: in one or two of the cases there was a slight rise in the temperature eighteen to twenty hours after the inoculation, but in only one case was no effect on the temperature noted. The last two cases afford excellent examples of the effect of the antitoxin on non-diphtheritic cases: both were early cases, so that a spontaneous fall of temperature can be excluded, and in both the temperature was not influenced in the slightest degree by the antitoxin. Skin eruptions following the antitoxin injections were noted in several of our cases; they have been noted by various observers since the inauguration of the treatment, but not enough stress has been laid on the fact that these eruptions are in all probability due to the serum *per se*, and not to the antitoxic agents contained therein." The deleterious effects of the serum of one species of animal when injected into a member of another species are too well known to be repeated here, but it is interesting to know that Sevestre, by injecting horse-serum in 20 centimeter doses into children with non diphtheritic sore throats, was able to produce urticaria and other forms of skin eruption similar to those observed after the use of the antitoxin. "The skin eruptions were the only bad effects, if one could so call them, which were observed after the use of the antitoxin. No other appreciable symptoms plainly due to the injection could be observed, nor did the examination of the urine give evidence of any such."

Suits for Malpractice on the Pacific Slope. Dr. James J. McKone of Tacoma, addressed the Washington State Medical Society on the subject of the aseptic treatment of injuries, especially of compound comminuted fractures. He warned his hearers that the modern doctrines of the text books on surgery have placed some dangerous weapons in the hands of the damage suit lawyers, who appear to now frequent the far West. As formerly in the East, so now in the West, surgeons are the game for which the lawyers go a hunting.

A generation ago, the majority of these actions were brought on account of deformity resulting from fractures and dislocations. "The laity, believing that every broken limb should recover perfectly, no allowance being given for the severity of the injury. To them a fracture is a fracture, be it a compound,

comminuted fracture of the femur, or a simple fracture of the fibula. A surgeon having the skill to save a badly mangled limb, that we as medical men know requires more ability than the average capital operation which contributes so much to the surgeon's reputation, is doomed forever to be pointed out by the patient and his friends as a careless and incompetent man, should necrosis or shortening follow the almost miraculous saving of a compound, comminuted fracture of the femur.

"Samuel D. Gross once said that compound fractures caused him more anxiety than all the rest of his surgery combined. Suits for malpractice in New England, once so frequent, are now almost unknown, because damages against medical men were very seldom awarded. One reason being that eminent men from Boston, New York and Philadelphia were always ready to respond to the call of a brother physician in trouble and testify to the truth; this, coupled with the fact that the supreme court had decided that the plaintiff in a suit for malpractice must show the defendant guilty, either of ignorance or gross negligence, a very hard thing to prove. But in these Western towns no man on earth can tell what a jury will do; and with every unsuccessful applicant for the police force, a lawyer, and with the supreme court, famous for reversing the decision of the lower court, and then reversing its own decisions, the profession must be watchful."

Dr. McKone gives the following as an instance of some of the traps that are laid in the path of the surgeon:

"I operated some months since on a patient for appendicitis, and he took me severely to task because there was a stitch-hole abscess. He said it was all 'damned carelessness' in the preparation, and that a physician had told him three months before that there was no need of pus ever forming in a wound made by a careful surgeon.

"I trust, gentlemen, that these remarks may not be wasted, and that though we may always use the utmost precaution to be perfectly aseptic in every surgical procedure, still we must not give our patients lectures on bacteriology and have them expect what they will not always get."

A Mexican Treatment of the Bite of the Gila.—A correspondent in California to the New York *Sun* writes regarding the bite of the so-called gila monster:

The death of three persons, one a naturalist from Chicago University, in Arizona in the last few weeks from the bite of the gila monster, has renewed discussion in this region concerning the terrible venomous nature of the reptile. Without doubt the gila monster of the alkali plains and the hot, dry mountain canyons of Arizona and the State of Sonora in Mexico, is the deadliest venomous creature known to the natural history of North America. Physicians say that the poison sets up a tremendous action of the heart, and the victim really dies of heart failure. The person who has been drinking to excess a few days or a few hours before he is injured by the gila monster is almost sure of death in half an hour after the bite. Many physicians in the Territory say that alcoholic stimulants are worse than useless for a person hurt by the reptile, but Walter H. Vail says he owes his recovery to a prompt use of whisky and the application of ammonia. Dr. E. G. Harper, who has been among the Huilipi Indians in Mexico for several years, in the interest of science, says the savages there certainly have a decoction that is a cure, if administered immediately, for the bite of the gila monster found in that region. "I have tried to learn from the Mexican Huilipis this anti-venom decoction," said Dr. Harper recently, "but it was useless. President Diaz says, however, that it can be had, and he will interest himself to get it for the benefit of the people of the United States, where a death from gila monster bite happens once in a while. The most wonderful feat I ever saw was down on the edge of the desert wastes in southern Sonora several years ago. It was a test of the power of the anti-venom preparation of the Huilipis. The chief medicine man claimed that he was a wizard, too, and that the great spirit *Moz no ha*, who dwelt on the peak of Orizaba, came down and helped him defy death from the most deadly poisons known among the Indians. At the time of the test I witnessed, the medicine man summoned a dozen of his young assistants around a cauldron, which was steaming and boiling with roots, leaves, horned toads, rattlesnake heads, and a score of other kinds of articles. I was told that this was the anti-poison medicine. In an hour the stuff was cool and ready for use. The medicine man bounded into the arena

with a 'ho-ho,' brandishing over his head two gila monsters. Then he varied the program by twirling them around his body and permitting them to crawl all over him. He teased the reptiles, poked his thumb into their mouths, and even put them up to his face. I am sure the man was bitten several times. We looked upon this daring feat with horror, while the Indians viewed it with superstitious frenzy, and showered upon the medicine chief all the presents they could command."

Murderous Malpractice by a Midwife.—The following narrative is compiled from the sworn statements of the husband mentioned, the physician who was called in to the moribund woman, the physician subsequently employed by the husband and the medical inspector of the Chicago Health Department:

On Wednesday, March 25, 1896, the husband of A. L., living at 31 Jane Street, Chicago, sent for Mrs. Susanna Hora, midwife, 663 Milwaukee Avenue, to attend his wife during confinement. The midwife endeavored to "get the child" until 10:30 p. m. without success and then left the house saying she would get some medicine and return. She returned with a package containing obstetric forceps and, after administering medicine to the patient, proceeded to apply the instrument. After three-quarters of an hour's continuous effort to extract the child she discarded the forceps and an hour later the child was born dead. Before the child was born the husband asked her if she needed the assistance of a physician, to which she replied that she was a doctor herself and that everything was all right except that the child "was a little high up." After the child was born she washed and doused the patient and, in reply to an inquiry, stated that everything was all right, but it would take longer than in other cases for the recovery of the patient and then departed. When the midwife returned next morning she was informed that the patient began vomiting soon after confinement and was unable to obtain sleep, to which she replied, "It is good that she vomits." Thursday evening the midwife gave the patient some pills with directions to administer throughout the night. Friday the patient grew decidedly worse and in the evening a physician was called in and found the patient in a state of collapse, pulse barely perceptible, temperature 101 degrees, cold sweat and a Hippocratic countenance. Digital examination being painful he was only able to detect a lacerated cervix and desisted from further procedure in anticipation of her death, which occurred shortly after his visit. The midwife in the meantime had demanded the remaining pills, and these not being forthcoming she urged that they be destroyed when found. When the physician was advised of the death of the patient he issued a certificate of death from puerperal fever, but subsequently notified the coroner. The husband refused to allow a post-mortem and the coroner dismissed the case, the body being taken to the Bohemian cemetery for interment. Meanwhile the Health Department having incidentally learned something of the facts, instituted an investigation which led to a post-mortem by Medical Inspector, Dr. Clausen, and Dr. Nahinsky, the latter being employed by the husband. Examination revealed the following conditions:

External appearances: Rigor mortis well marked. Beginning decomposition most marked over lower abdomen and thighs; dark bluish discoloration over both groins and vulva, also of mucous membrane of vagina and perineum. A perforation about one-fourth of an inch in length about four inches from the navel and on the level of same on both sides, presumably made by embalmer's trocar. No pelvic deformities to be detected and no laceration of perineum.

Intra-abdominal examination: Intestines perforated (obviously by trocar) in various places, two of which perforations were located at junction of sigmoid flexure and the rectum and were about one-eighth of an inch in length. Marked pathologic changes in the peritoneum found in the pelvic floor behind the uterus. In the cul-de-sac of Douglas a laceration with ragged torn edges was found communicating with the vagina, which readily admitted four fingers. The peritoneum in this vicinity was darker in color and infiltrated, likewise the edges of the laceration. The mucous membrane of posterior and upper wall of vagina and the cervix were lacerated. The uterus was intact and enlarged. Its cavity contained some fragments of placenta and a small quantity of dark clotted blood. Bladder empty and normal and ovaries and tubes normal. Other abdominal organs apparently normal. The infant, well developed and large, presented a dark, discolored swelling above and behind each ear and a linear depression about one and one-half inch on each side of neck, parallel to the upper posterior border of the sterno-cleido-mastoid muscle.

As a result of these disclosures information was lodged with the attorney of the State Board of Health, and the husband

retained an attorney to prosecute the midwife in a civil action for damages. These proceedings were cut short by the midwife committing suicide by carbolic acid poisoning, April 11. During the investigation it was alleged by various persons that she had caused the death of a number of other 'unfortunate parturients, two or three within a short time of this case. According to the official register, Susanna Hora had been in practice as a midwife in Chicago some fifteen years, her State certificate having been issued Nov. 1, 1881, on alleged credentials from the University of Buda-Pesth, dated July 3, 1875.

In laying the above facts before the State Board of Health, Dr. Reilly, Acting Commissioner of Health, took occasion to say: "While this case has some unusual features it does not by any means cover all the horrible details of the unrestricted practice of many midwives, the criminal abortions performed by them, their numerous infanticides and frequent butcheries. A recent well-authenticated instance of such butcheries is that of a midwife who amputated an inverted womb after labor for a tumor, and in which operation she was 'assisted' by a physician holding a State certificate. The prosecution was a failure, because in the absence of the amputated structure it was impossible to prove the non-existence of a tumor. In fact, prosecution in these cases is rarely successful. There are now three licensed midwives in this city under indictments of long standing and concerning whose guilt there is no shadow of doubt. They are still plying their nefarious vocations unrestricted, except in so far as this department refuses to recognize their certificates of causes of death. This, however, gives them little or no concern, since they can readily obtain a certificate from a recognized physician for a small fee."

The action of the State Board is told in the editorial, "A Much-Needed Reform Begun."

Practical Notes.

Subconjunctival Injections of Quinin.—Proceeding on the basis of the action of quinin on the leucocytes in the blood, Bossalino, of Turin, has been injecting bichlorid of quinin, 1 to 400, in twenty cases of ulcers and abscesses of the cornea, complicated with hypopyon and even iritis in some cases. The injections were only slightly painful, and they produced a cure in ten to twenty days, while the leucoma afterward was much more transparent than usual.—*Gazzetta degli Osp. e delle Clin.*, April 4.

Thyroid Treatment of Obesity.—Maragliano confirms the results of the treatment of obesity with thyroid tabloids, and states that he has also found them efficacious in a case of scleroderma. He does not attribute this efficacy to the iodine in them, as he has often treated obesity with preparations of iodine, and the results are almost nil, unless the diet is materially modified, which is not necessary with the thyroid treatment a most important point in its favor.—*Gazzetta degli Osp. e delle Clin.*, April 4.

Hemorrhoids and Enlarged Prostate Relieved by Double Castration.—Dr. John Homans, at the Massachusetts General Hospital, had occasion to treat a man of 64 years for retention of urine due to enlarging prostate, the symptoms of which began to be noticed about four years ago. Double castration was performed and six days later urine was passed voluntarily; four days after that the use of the catheter was permanently discontinued. Twenty days after operation the man was again actively engaged in business, and was able to report that the operation appeared to have entirely cured his piles from which he had formerly been a great sufferer.

Typhoid Treated Exclusively with Phenacetin.—Bignami reports his success with this treatment in his private practice, in the *Gaz. degli Osp. e delle Clin.*, March 21. He had only six fatalities, which were mostly due to unhygienic surroundings. It produced a profuse diaphoresis in every case, to which he ascribes its beneficial action. Queirolo has shown also that phenacetin has a neutralizing effect on the typhoid poison in the blood, and the cases above demonstrated that it has a direct abortive effect on ileo-typhoid especially. Bignami administered 3 grams in six doses at intervals of four hours, for a week, reducing the dose to 2 or 1.5 grams with children

or elderly people. After the first week he continued with $\frac{1}{4}$ to $\frac{1}{2}$ gram every six hours, as long as the temperature was above normal. There were no inconveniences from its use, neither vomiting, hematuria, collapse or kidney troubles, only in a few cases a slight transient cyanosis.

Treatment of Anal Fissures with Cocain and Ichthyol. Surgical treatment is often accepted as indicated in these cases, but it would be seldom required if the fissure were first treated with cocain at 1 per cent. for five minutes and then cauterized with one or two drops of ichthyol. A recent fissure can be entirely cured with ten of these simple treatments, while an old one requires more, perhaps twenty, and must be treated its entire length, dilating the sphincter with a Nelaton dilator.—Cheron in the *Rev. des Mal. des Femmes*. Quoted in April *Union Méd. du Canada*.

The Revolution in Obstetric Treatment is becoming more evident every day, as asepsis is gradually displacing antiseptis. Vaginal douches were discarded first: and Leopold and Spoorlin have inaugurated an entire new method to determine the position and presentation of the fetus by abdominal palpation alone. In 1,000 cases thus treated the diagnosis was at fault in only 6.5 per cent. Kroenig and Ries substitute rectal for vaginal examination, and Strassmann has devised a series of external manipulations, under chloroform, which will do away with the forceps in many cases, and is, he claims, the method *de rigueur* when the fetus is dead. Remarkably favorable are the results of this entire avoidance of the vagina, which is left intact to its own secretions in all normal cases. Mermann reports no fatalities in 1,200 cases thus treated, and all normal but 5.7 per cent.: Leopold reports 1,382 cases with a mortality of .07 per cent. and morbidity in .65 per cent.; Ferratta had a mortality of .05 per cent. in 800 cases.—From an article in the *Union Médicale du Canada*, April.

To Ward Off Malaria. Laveran announces as the results of his investigations, that the preventive dose of quinin is 0.20 to 0.30 gram every day, or twice this amount every other day. This is a larger dose than is usually given, but it has been found that it produces no deleterious effects on the digestive organs, even taken for months at a time, and actually acts as a tonic, stimulating the appetite and improving the general health if taken at meal times. It absolutely prevents severe fever attacks, and is almost certain to ward it off entirely. By its bacteric action it kills the hematozoa or at least transforms the blood into an unfavorable medium for its development. Laborde recommends the hydrochlorid, or better still, the hydrochloro-sulphate of quinin, and in violent attacks it is better; but as a preventive Laveran considers the ordinary sulphate equally as good and it is less expensive. Laveran mentions the curious fact that it is impossible to experiment on animals in regard to the effect of malarial poisons as they are unaffected by it. (See this JOURNAL, pages 493 and 690, March 7 and April 4.)

Iodism. The *Semaine Médicale*, April 8, contains a detailed study of the toxic effects of iodine on the system, with a review of the cases of iodism on record, which shows that few organs are exempt from possible disorders following its use. None of the iodids are free from possible deleterious effects. The table below shows the percentage of iodism in one to four hundred cases observed:

	None.	Slight.	Moderate.	Severe.
Pot. Iodid	23	38	23	16
Sodium Iodid	34	11	15	10
Ammon. Iodid	22	32	31	11
Str. Iodid	22	34	28	16

Only 25 per cent. of the cases are free from complication but it is not severe except in 10 to 15 per cent. and in some of these the system becomes accustomed to it in time. The most frequent and serious consequences are coryza, eruptions, renal and nervous troubles. There are no means of determining its effects beforehand, as they seem to depend upon some idiosyn-

crasy, impossible to foresee except perhaps in renal troubles. It is also established that the tendency to produce iodism, and the severity of the attack, is directly dependent upon the size of the dose. There is no preventive medication possible, except administering the iodine in very small doses to begin with (50 centigrams). Belladonna for severe coryza, and bicarbonate of soda in severe cases of iodism, are the only remedies that have proved beneficial.

Subcutaneous Injections of Mercury in Syphilis.—The *Annales de Derm. et de Syphil.* for March, devotes fifty-four pages to a symposium of reports on the treatment of syphilis with injections of mercury. The forms used were: Calomel (Fournier, Portalier, Barthélemy and others); bichlorid or cyanid of mercury (Abadie); olive oil and mercuric iodid (Lavarenne); gray oil (Hallepeau). The reports embrace a large number of cases, and the efficacy of this treatment seems to be established beyond a doubt, but its disadvantages (pain, occasional abscesses at the injecting point, and rare cases of serious distress) are such that nearly all agree that its use should be restricted to severe, urgent cases, which are often cured as if by magic. Relapses are liable to occur, unless preventive injections are made from time to time. Hallepeau denounces the use of cocain with them. The injections are all made in the buttocks. Barthélemy advises a weekly injection of calomel during the whole time that the blood is contagious. It has been the experience of several that patients much prefer this treatment to pills or local friction, etc. Lavarenne has treated tabes successfully and reports one absolute cure, and the arrest of another quite advanced case to such an extent that, during the four years of the treatment, the patient has not been obliged to interrupt his business a single day. Fournier considers the specific indication for its use the lingual syphilitic lesions, which he has seen swept away almost instantly by injections of calomel. His formula is: Calomel, 5 centigrams; pure cocain, 1 centigram; olive oil, q. s. to make 1 c.c. Applied with a Feulard syringe. Scarenzio mixes oil of vaselin with his calomel. Abadie's formula is: Mercuric cyanid, 50 centigrams; cocain hydrochlorate, 50 centigrams; distilled water, 50 centigrams.

Syphilitic Chancre on the Chin.—The leading article in the *Bulletin Médical*, March 29, urges the extreme importance of differentiating at once the signs of extra-genital syphilitic lesions, acquired accidentally, so that they can be treated promptly, and covered close with some plaster which will prevent the further infection of the subject and also the infection of those around him. The writer recommends Vidal's red minium and cinnabar plaster, as less irritating than Vigo's, first washing the surface with Van Swieten's solution, with other measures as necessary. The barber shop is the most frequent means of contagion by the razor or brush, which is disinfected even less than the razor. The infection may occur on leaving the shop through some scratch or pimple. Chambermaids and other attendants on persons with syphilitic lesions are very liable to acquire these chancres on the face, which are most frequently misunderstood at first, and the infection allowed to spread in a most dangerous manner.

Rupture of Spleen; Three Splenectomies with Recoveries.—The London medical periodicals have given considerable prominence to the discussion before the Clinical Society, of that city, of three cases of operation by Mr. Pitts and Mr. Ballance at the St. Thomas Hospital, done for rupture of the spleen. One case was that of a man, aged 36 years, admitted to hospital in the early morning of October 12 last, under the care of Mr. Pitts. He had fallen from a height of seven feet on to an iron girder, striking his left side. He complained of pain over that side and was slightly blanched, but otherwise apparently well. At 11 A.M. his condition became suddenly worse; he was deathly pale and almost pulseless, the extremities were cold

and the respiration quick. Both flanks were dull, but the dullness on the left side could not be wholly got rid of by change of position, and the man complained of great pain in the abdomen and said he thought he was dying. Restoratives were employed, and by 3 P.M. he had rallied sufficiently to make operation a reasonable thing to attempt. In the meantime it had been observed that the quantity of fluid in the abdomen had greatly increased. On making the median incision an enormous quantity of blood gushed out, the peritoneal cavity being literally distended to its utmost capacity. When the spleen was brought into view it was found to be ruptured completely across, the vessels in the hilum being also torn. The cleansing of the peritoneum from blood and clot took some time, and the wounds were closed in the usual way. The patient gradually rallied and at the end of a fortnight he appeared in every way as if completely convalescent. He then commenced to lose ground without manifest cause and soon presented the appearance of extreme anemia. His aspect was withered and sallow; he lost three stone in weight and became extremely feeble. There was a daily rise of temperature and the pulse was rapid. He also had fainting attacks, headache, great thirst, severe pains in the abdomen, and passed an excessive quantity of urine. The red blood discs numbered 2,500,000 and the white corpuscles 17,000 per cubic millimeter. It was determined to treat this patient on general principles. He was given cod-liver oil and bone marrow, but it was not until arsenic was administered that any real improvement was observed. In about two months the number of red and white corpuscles in the blood became normal. He gradually regained weight and at the present time was in robust health and following his occupation as a laborer, but all the external lymphatic glands could be felt to be definitely enlarged.

The second case was that of a lad, aged 10 years, under the care of Mr. Ballance. When admitted, September 11, the patient was in collapse and evidently suffering from severe shock. He was pale and the skin was clammy, respiration hurried and diaphragmatic. The abdomen was held rigidly during respiration and was acutely tender to palpation, especially in the splenic and iliac regions. Dullness in both flanks, that in the left flank varying with position. After oscillating a good deal, operative interference became imperative, so the abdomen was opened below the umbilicus. On opening the peritoneum, much liquid blood poured out and an incision was made in the upper part of the linea semilunaris. Blood and clots welled up, and on examining the spleen it was found to be ruptured. A ligature was therefore applied and the organ removed, a lienculus being found and left in. The lad made a good recovery and left the hospital on October 4. The injury was caused by a blow with a cricket ball five days before admission, so that his condition on admission was due to secondary hemorrhage from the spleen.

The third case was a woman, aged 45, who was admitted September 15, having been run over by a cab. She was extremely collapsed, and complained of intense pain in the left side. A catheter was passed and a little blood and urine was withdrawn. The abdomen was opened in the middle line when much bloody fluid escaped. Another incision was then made in the upper part of the left linea semilunaris, and the spleen was found to be transversely ruptured. It was removed, the pedicle being tied with silk. About a fortnight after the operation her condition grew worse, the temperature rose to 102 every day, the pulse was rapid and her general condition was one of extreme feebleness. There was a diminution of red cells in the blood and an increase of leucocytes. This state continued for about a fortnight, when she was put on extract of spleen and raw marrow. From this date she gradually improved, and by November 19 she was able to walk down stairs without assistance.

The first of the above cases, that of Mr. Pitts, is condensed from the report in the *London Lancet*; the other two cases, both of which were under the care of Mr. Ballance, are quoted from the *Medical Press and Circular*.

Mr. Pitts further stated that the number of cases of ruptured spleen he had seen post-mortem after removal was very small compared with the number of fatal cases in which death had taken place as a consequence of the hemorrhage. They had laid stress upon the fact that the spleen ought not to be lightly removed. Their experience of the removal of the wandering

spleen has been that no special symptoms followed the operation. In Case 3 the patient was practically moribund, and the abdomen was as full of blood as it could be. When practicable he would prefer suture of the tear to the actual cautery. The latter, moreover, necessitated pulling the spleen out of the abdomen, and he did not think it would be a scientific or a satisfactory procedure. He promised that they would do their best to obtain the subsequent histories of these patients.

Detroit.

THE DETROIT MEDICAL AND LIBRARY ASSOCIATION had its usual weekly meeting Monday, April 20, at which several important matters were brought up.

THE WAYNE COUNTY MEDICAL SOCIETY met at the office of Dr. Kenneth Gunsolus, Thursday, April 23. Dr. Frank S. Hough read a voluntary paper on "Counter Irritants," which was discussed by a number of the members. After the literary feast of the evening, Dr. and Mrs. Gunsolus invited the members of the society present, about seventy, to repair to the dining room where a banquet was served. Music made the remaining part of the evening pleasant.

HEALTH OFFICE REPORT for week ending April 25: Deaths under 5 years 34, total 79; births, male 40, female 43, total 83. Contagious diseases: Diphtheria, last report 3, new cases 2, recovered 2, died none, now sick 3: scarlet fever, last report 21, new cases 9, recovered 5, died 1, now sick 24: smallpox, none; measles, last report 1, new cases 3, recovered 2, died none, now sick 2.

Louisville.

LICENSE.—The common council recently passed a license law which reads as follows: "Each practicing attorney or counselor at law, physician, dentist, surgeon, architect, civil engineer, chiropodist, veterinary surgeon or dentist shall pay a license as follows: One whose yearly business amounts to less than \$2,000, shall pay an annual license of \$10; one whose yearly business amounts to \$2,000 or over, and less than \$5,000, shall pay an annual license of \$20; one whose annual business amounts to \$5,000 or over and less than \$10,000, shall pay an annual license of \$40; one whose yearly business amounts to \$10,000 or over shall pay an annual license of \$100. Should any of the foregoing parties be associated in a firm, each member of the firm shall pay a separate license." A member from each of the various medical societies in the city has been appointed to confer together and employ counsel to test the legality of such a law in the courts, their claim being that it is a counterpart of the income tax which was declared unconstitutional by the supreme court of the United States.

Philadelphia.

A PROPOSED SEMI-CENTENNIAL CELEBRATION OF THE AMERICAN MEDICAL ASSOCIATION.—At the meeting of the Philadelphia County Medical Society held April 15, the following resolutions were unanimously adopted:

WHEREAS, The AMERICAN MEDICAL ASSOCIATION completed its organization and commenced its actual existence in the city of Philadelphia during the first week of May, 1847; therefore be it

Resolved, That a committee of three be appointed by the Chair to publicly urge that the ASSOCIATION celebrate in 1897 its fiftieth annual meeting with ceremonies appropriate to its long and successful career; and be it

Resolved, That the delegates of the Philadelphia County Medical Society to the meeting of the AMERICAN MEDICAL ASSOCIATION at Atlanta be instructed to extend the ASSOCIATION a cordial invitation to hold its semi-centennial meeting in Philadelphia, the city of its birth.

The President accordingly appointed Drs. John B. Roberts, James C. Wilson and William M. Welch to act upon this committee.

AUGUST WEATHER IN APRIL.—According to the meteorologic records, which have been regularly kept at the Pennsylvania Hospital since 1824, the week ending April 18 gave the highest temperature record for the past seventy-two years. The thermometer standing in the garden of the hospital indicated 92.5

degrees, while that of the United States Weather Bureau on the top floor of the postoffice here marked 93 degrees at 4 P.M. The highest recorded observation of high temperature in April, in this city, previous to the above, was in 1888, when it got up to 90, surpassing by one degree the highest previous April temperature, which occurred in 1830. The sudden onset of summer weather with its accompaniment of heat prostrations and insulations, caught the hospitals by surprise, and the usual method of erecting tents under the shade of the trees for treating such cases could not be carried out because the leaf-buds only burst within the last fortnight and the leaves are as yet too small to give any protection from the sun's rays. Of the score or more of cases which were taken to the hospitals the larger proportion were cases of heat exhaustion, but several cases of insolation were reported at the coroner's office.

SUDDEN DEATH OF THE CORONER'S PHYSICIAN.—On the 16th ult. Dr. Wm. K. Mattern, physician to the coroner's office, was suddenly seized with severe pain in his chest and shortly afterward expired. He seemed in his usual health early in the day and made a post mortem examination a few hours before his death. He had recently performed an autopsy upon the body of a woman, who had died from septic poisoning, and had spoken of being overworked and an assistant had been promised him. A post mortem revealed pyemic abscesses in the kidneys and liver, and rupture of a pulmonary artery, the result of sepsis. It is strange that, with such marked lesions, he had not experienced more disability. The predecessor of Dr. Mattern, Dr. Robert H. Taylor, likewise lost his life from blood poisoning contracted in the performance of his duties. It is believed that Dr. Formad's death, a few years ago, may also have had a similar explanation, as he died after a few days' illness, of acute pneumonia.

THE RÖNTGEN RAYS.—The X rays and skiagraphy are becoming of daily utility in surgery in locating foreign bodies and in determining the relative position of fractured bones after all the dressings have been applied. Last week a patient of Dr. T. G. Morton, suffering with metatarsalgia, had her feet skiagraphed by Professor Goodspeed, and a negative was obtained by an exposure of twenty-three seconds, which afforded a clear photographic print of the bones of the foot, clearly demonstrating the distortion of the bones of the phalanges and the pinching of tissues between the base of the first phalanx of the little toe and the head of the adjoining metatarsal bone. The picture fully sustained the views of Dr. Morton as to the pathology of this peculiar form of neuralgia and illustrated, even better than a diagram, the method of relief to be obtained through operation.

THE MEDICO-SURGICAL COLLEGE is making extensive improvements and has begun work upon a large clinical amphitheater adjoining the hospital, which is estimated to cost \$180,000 and will be ready for the next session.

GUAIACOL IN TYPHOID FEVER.—Dr. H. G. McCormick, of Williamsport, by invitation, read a paper before the Philadelphia County Medical Society on the therapeutic uses of guaiacol. He presented a number of clinical charts illustrating the prompt antithermic effect produced by painting 20 to 30 drops of guaiacol upon the surface of the abdomen. He had used it in 77 cases making 850 applications, without any accident or serious depression resulting from its use. He extolled its use in typhoid fever, preferring this to the cold bath treatment, which he considered impracticable in private practice. Out of 56 cases of typhoid fever treated by guaiacol, externally and internally, 55 recovered; the fatal case entered the hospital late in the second week and died of perforation two days after admission. From his own experience he considered guaiacol used internally as a disinfectant of the alimentary canal and externally as an antipyretic, as the best treatment of the disease.

ANTITOXIN TO BE DISTRIBUTED FREE.—The Bacteriologic

Laboratory of the City Board of Health under the efficient management of Dr. Bolton, has been manufacturing diphtheria antitoxic serum for use in the Municipal Hospital. There being a sufficient supply on hand to warrant its distribution to the poor, the Board of Health has publicly offered to supply the antitoxin and has appointed a physician to administer it for other physicians in appropriate cases. It is also stated that the services of the Philadelphia Bacteriologic Laboratory will hereafter not be confined to this city, but examinations in cases of suspected diphtheria, will be made and culture tubes sent by mail to any part of the State of Pennsylvania, without charge.

DR. ERNEST B. SANGREE has been elected to the Chair of Pathology and Bacteriology in the Vanderbilt University at Nashville, Tenn.

THE PUBLIC SERVICES.

Army Changes. Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from April 18 to 25, 1896.

Capt. Ashton B. Heyl, Asst. Surgeon, is relieved from duty at Ft. Thomas, Ky., and ordered to Ft. Canby, Washington, for duty.

First Lieut. Henry A. Shaw, Asst. Surgeon (Ft. Snelling, Minn.), is granted leave of absence for one month, to take effect about May 2, 1896.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending April 25, 1896.

Asst. Surgeon H. La Motte, detached from the "Franklin" and granted four months' sick leave.

Asst. Surgeon M. K. Johnson, detached from the Naval Laboratory and Department of Instruction and ordered to the "Franklin."

Change of Address.

Armstrong, S. T., from Asbury Park to 71 Maiden Lane, New Rochelle, N. Y.

Eaton, Roy R., from Chicago, Ill., to Lowell, Mich.

Furay, Chas. E., from St. Joseph's Hospital to Rooms 210-11, Brown Block, Omaha, Neb.

Greely, G. H., from Hillsboro to Thornton's Ferry, N. H.

Kent, Jas. L., from Bertha to Dublin, Va.

Kelley, Warren, from Little Rock to Carlisle, Ark.

Luebbers, Alfred, from St. Louis, Mo., to 256 N. Pearl St., Dallas, Texas.

Lersche, E. P., from 192 S. Robey St. to 877 Spaulding Av., Chicago.

Murray, R. D., from Key West, Fla., to Marine Hospital, Mobile, Ala.

Norris, M. D., from Catonsville to Sykesville, Md.

Nance, Willis O., from 119 Garfield Boul., to "Suite 803 Venetian Bld.," residence 5466 Monroe Av., Chicago, Ill.

Randall, F., from 60 Liberty St. to 72 William St., New York, N. Y.

Waters, L. C., from 669 W. Monroe St. to 463 W. Monroe St., Chicago.

VOL. XXVI.

CHICAGO, ILL., MAY 9, 1896.

No. 19.

ADDRESSES.

THE ADDRESS OF THE PRESIDENT.

Delivered at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY R. BEVERLY COLE, M.D.

SAN FRANCISCO, CAL.

Perhaps never before in the history of this ASSOCIATION has its presiding officer, elevated to his exalted position through the kind suffrage of his confrères, felt at a greater disadvantage than at present. Fully imbued with an appreciation of the dignity and importance of the station, and the difficulties attendant upon the proper discharge of the duties that devolve upon him, I must crave your kind indulgence for any errors of judgment as expressed through my rulings, and trust they may be ascribed rather to an excess of ambition to do right than to a willful carelessness or indifference.

Fifteen years ago in the beautiful city of Atlanta I was made your First Vice President, my superior officer being the distinguished surgeon of New York, Prof. L. A. Sayre, and I recognize it as an interesting coincidence that it should be my privilege to return to this Athens of the South to round out my official connection with this, our loved institution.

Indeed, my present visit is fraught with the greatest interest to observe the great changes that have been wrought in the period, as expressed through the wonderful growth in population and business, whether in manufacture or trade; the evidences of refinement and culture as exhibited in your lovely homes and grand public and private structures, and last, but not least, it is apparent on every side that that generous hospitality for which your people have ever been distinguished has not only not abated, but, if possible, increased in the same ratio with the advances made in every other direction.

At the time alluded to these people had but recently passed through the trials, privations and sufferings incidental to a most cruel civil war, than which nothing is to be more deplored, the indications of which were more or less noticeable in every surrounding. But, lo! what a change! In lieu of the remains of portentous breastworks and other requirements of physical strife, there has arisen as though through the operations of Aladdin's lamp or some magic wand, this most picturesque and prosperous city, and to-day we, from the North, East and West, again grasp your hands that are so cordially extended with that warmth and unity of purpose that express in silence more than it is possible to utter with the lips.

These occasions that bring us annually together serve many purposes. They are in a sense a family reunion, each individual of which is interested in the welfare of the other, and the whole in the one great, noble and God-like object of studying the best methods for alleviating suffering and prolonging life. These

convocations also serve to bring the members of our profession in closer touch with each other, and establish friendships that in many instances endure throughout life.

It is not my purpose or intention to occupy your valuable time in delivering an oration, however propitious the occasion, nor yet to expatiate upon themes that are now past; but for a few moments only, to call your attention to several living questions that seem to me, at least, to be of vital importance, and deserving of our earnest attention, and in some directions appeal to us very strongly for action.

It can not have failed to attract your attention that the tendency of the "Grand Army" of medical men of to-day is to depreciate the dignity of their profession and bring it to a commercial level. When the older members of our beloved profession were yet young, to be a physician was considered the greatest of honors and the holiest of callings. The medical man was looked upon by those whose ailments he ministered to, in a sense, as a saint and his word was law, to disobey which was a mortal offense, and the opportunity to repeat which was never furnished. The doctor was a gentleman as well as a scholar, commanding the love and esteem of his patients and the community in which he lived. This was the rule; but I fear that now it is the exception. The reason for this is undoubtedly to be found in the multiplicity of so-called medical schools with their natural bidding for patronage, the low standard of preliminary requirement, the limited curriculum and superficial examinations. As the outgrowth of this condition we have the ranks of the profession overcrowded, and those who are in any manner qualified together with those who are not, in order as speedily as possible to become prominent, resort either to the making of books, the authors of which are too often without the least experience in the science of which they profess to treat; or organize medical schools and thus bring about the condition just alluded to. From my standpoint of reasoning the only remedy for these growing evils is governmental interference and regulation of medical education, or certainly of professional examination. I would suggest for your consideration the propriety of referring this matter to a special committee with a request that they report at the next session of this ASSOCIATION.

I am perfectly conscious that in some of the States recent new departures have been made or attempted, giving evidence of a disposition to correct errors, but are these new requirements and regulations faithfully carried out? Is the announced advance much more than a species of advertisement intended to appease the anxiety and restless spirit of those who have been laboring assiduously to bring about a revolution in our system? I fear not. True, New York has taken, through its Board of Regents, a decided step forward, which if religiously carried into effect would meet and correct many defects, and the result would be

highly satisfactory; also can it be said that Illinois and perhaps some other States are making efforts in the same direction. But my observation does not greatly encourage me in the hope I have so long cherished; yet I have not relinquished this hope and trust that time will reveal these steps to be properly directed and followed. What has been said of New York and Illinois will apply with equal force to other States where these new departures have been taken.

I am well aware that this question has been repeatedly presented in one form or another, but the results have been *nil*, or at most, unsatisfactory, and being convinced that nothing will be accomplished except through agitation, I have once more ventured the attempt to set the ball in motion.

A member of our profession, also a teacher, recently in a letter addressed to me, suggests that in this address I urge the members of the ASSOCIATION to secure legislation in their respective States of such character as to bring about improvement in this direction. Another, with equal earnestness suggests that there should be a national board of examiners created by Congressional provision composed in part of the heads of the medical bureaus of the army and navy, that shall examine all applicants as to their qualifications to practice medicine and surgery, and to such as are successful a certificate shall be issued, setting forth the fact, which would without doubt be accepted by the examining boards of the several States and a license be issued thereon, entitling the holder to engage in practice within that State. This, he says, would leave the State boards independent of the national, in so far as the power to issue a license, and for proper cause revoke the same, may be concerned.

It may and doubtless will be argued by some of you that the efforts of the American Medical College Association within the past few years have brought great changes in the desired direction. It must be admitted that improvement has been effected, but so very slowly, and the usage of many of the schools to evade the laws established by the Association is so general, that the good resulting is small, very small, and the manifest reluctance of so many now within the organization to embrace the last advance, viz., the adoption of the four-years requirement, gives but little promise for the future; and again, whilst of the whole membership of the College Association, quite a number, seemingly, as announced through their annual circulars, desire to elevate the standard of preliminary qualification of applicants for admission, I fear that but few adhere to what they profess; in other words, whilst not a few colleges announce a liberal preliminary education as a prerequisite to admission, the examination of matriculation is a mere farce, conducted usually as they are by one member of the faculty, and consisting generally of no other questions than which a kindergarten pupil should be able to pass.

So long as these examinations of matriculation are conducted by members of the faculty of the medical schools, just so long will these evils continue, and so long as the professional examinations for degrees are conducted by interested parties, just so long will the ranks of the noblest of professions be filled with uneducated, untrained so-called doctors.

The medical profession is over-ridden with quasi-medical schools, and the community with so-called dispensaries, where small fees are paid and yet smaller service received, resulting in a growing distrust and a

contempt on the part of the laity for the grandest and noblest of all sciences, as practically exhibited recently by the New York Life Insurance Company and the Equitable Life Assurance Society in adopting a graded scale of fees for medical examinations; competition is the explanation; and these and other corporations, avaricious as they always are, worshipping at the shrine of gold, see only the few thousands saved to their respective companies, but fail to see the enormous loss that will be entailed in the end. No man qualified to make a thorough examination, such as is required by insurance companies, if he be properly imbued with the value and importance of his service, will or can assume the responsibility attaching to his function as an examiner, without an adequate return. Surely the fee of \$5 was small enough, and the offer of any sum less is simply an insult to an educated physician and a bid for cheap, unscientific service, which can be had from the ranks of the unskilled and irresponsible. But are these services such as a sound insurance corporation desire? I think not; but they ought to have none other or be compelled to pay for it. Let every examiner plant his foot and decline employment without adequate compensation; let it be published to the world that certain companies employ incompetent men, or paying cut fees receive cut services, and very soon will they discover their mistake and be brought to a realization that the best goods always command the best prices.

As has been said, I know that this question has been discussed times without number, and is annually considered by the College Association, but I am beginning to feel that after all it is better to agitate in this ASSOCIATION, from which the College Association sprang, than to depend wholly and solely upon the latter.

Cicero once said to Piso, with whom he had had a disagreement: "You have crept into honors through the reputation of your ancestors, like whose smoky busts you are only in color." So may it be said of the great mass of the medical profession of to-day; they have crept into its ranks, induced through the exalted reputation given it by the mighty brains of its greatest representatives, like whom, however, they are only in title. Whilst I thus discuss this burning question in language perhaps a little too plain, I do not wish to be interpreted as saying or thinking that this great and glorious country of ours is without schools equal to any to be found in the world, or teachers who are not the peers of the best. On the contrary, from the standpoint of one who has enjoyed peculiar opportunities for observation in many of the larger educational centers, I feel justified in asserting that the United States, including Canada, can proudly boast of as good schools and brilliant teaching material as any country, and further, that its general system of medical education in some particulars (because of its great practical character) is vastly superior to that pursued in many, which has produced and is producing some of the brightest, ablest and conscientious original investigators, through whose labors the literature and field of science are being daily enriched, building for themselves individual monumental reputations, and for the profession of which they are such conspicuous and shining lights, winning the esteem and admiration of thinking men, and the love and devotion of those in whose behests they are laboring.

The list of such men as have been wholly educated at home is too lengthy to present at this time; with

many you are, or have been personally acquainted, whilst the names of others have been handed down through the long line of professional literature, and are to be found emblazoned on every page of medical history, there to endure so long as time shall continue.

But such men are not of the class to which we have been alluding, and with which our profession is so overcrowded; these first have taken up the science through a love for science and an exalted appreciation of the duty of man to man, the God-like character of their calling, and a desire to possess a self-approving conscience; these considerations led them to a proper preparation, such as is secured only through unremitting study, assiduity and honesty of purpose.

These are the men who should constitute the beacon lights of the profession, guiding the younger ones contemplating the adoption of medicine as a profession. Of this class there are within the sound of my voice many to-day, and I appeal to you in the name of science and humanity, to bend your energies, exert your every influence, and lend your aid to the end that this noble profession as represented through its rank and file, shall no longer be the subject of ridicule and scoff, but within the near future command as it should that esteem and respect to which its exalted character and purposes entitle it. It is not sufficient for the Association of Colleges to say that it proposes to do thus and so, or that it has done so and so, but we want an earnest determined effort on the part of you who are in direct and immediate interest to see that that which is promised is performed, that there may be no more gerrymandering as to preliminary requirements to the study of medicine and that the highest possible standard be set up, remembering always the aphorism:

VIRTUS IN ACTIONE CONSISTIT.

Another quest of grave importance and of which I think this ASSOCIATION should take cognizance and suggest a remedy, is the total abstinence of reciprocity between the United States and foreign countries as to laws governing the right to practice. Why Americans should be required when taking up their abode in Germany, Great Britain and even in the territory of our first cousins, the Canadas, to undergo an examination preliminary to securing a license, whilst *our* portals are flood-gates through which every country of the earth pours its overplus of medical men, or rather to put it more correctly, why our country should receive with open arms, without let or hindrance the excess of product of foreign schools without requiring of them the same as is required of us? I can see no reason, and am distinctly of the opinion that the time has arrived when we should be heard, and something done to arrest the strides of this rapidly growing wrong.

Looking over the medical registers of the various countries it will be easily discernible that the number of graduates of foreign schools is greatly in excess of the number who remain at home and engage in the field of their profession. What has become of those who do not remain at home? The answer is, that from three-fourths to seven-eighths emigrate to America, and strange to say, I am led to believe that the very regulations governing their examinations are in a large measure responsible for this condition of things. From the best sources of information at my command I learn that in Germany the examination for the doctorate is much less stringent than the "Staats Examen."

The former confers no rights, and the latter is indispensably necessary to entitle the candidate to the privilege to practice in the empire; consequently the student who desires to emigrate may pass the required examination for the degree of "Doctor in Medicine," or before he reaches this may conclude as no examination is required in many of the States of the Union he will take his certificate for the several semesters he may have attended and go to America, "The land of the free and the home of the brave," where he may practice his (in many instances) imperfectly acquired profession and not infrequently impose upon the credulity of the people. In many cases the university examination is conducted by the same men who compose the board and conduct the "Staats Examen," which seems at least to be paradoxical, but which I believe is nevertheless true; this system is fraught with possibilities that bode no good.

The university examination for the doctorate is an easy one, and the fee for the same goes to the faculty, whilst that paid for the "Staats Examen" goes to the government; ergo, when we consider that the fee for the doctorate goes into the pockets of the examiners, and that for the state's examination goes to the government, and that the candidate is permitted to engage in practice in his own country, thus becoming a competitor of his examiners, it is easy to see to what extent the custom may be abused. I mean no offense, and do not charge that abuses are practiced, but merely call attention to possibilities, and as all men are human, it is not probable that the Germans differ from other people.

For the degree, it is not even obligatory that the foreign student should attend either the didactic or clinical lectures, and the examination, as has been said, is so easy for such that it has been and doubtless is an inducement for many who possibly failed at home to repair to this country with a diploma, which through want of knowledge on the part of our people, carries more prestige than a degree from one of our home universities.

Coming nearer home, to our very borders, we find that in the several provinces of Canada not only is it impossible for an American to receive a license without examination, but also is it impossible for one having a license in one province to practice in another, and that no Canadian with Canadian qualifications is eligible to registration in Great Britain.

Now, whilst we recognize the excellence of their, or at least some of their, medical schools and the elevated standard of preliminary requirement observed, it seems somewhat singular that this want of accord between the several provinces should exist, which is, indeed, attracting their own attention, and I see that at the meeting of the Canadian Medical Association in 1894, a committee on "International Registration" was appointed, which reported at its last meeting held in Kingston, "that it regretted that the system which at present obtains," "prevents the names of medical practitioners in the Dominion being placed on the British register, which the council of medical education of Great Britain has more than once signified its willingness to grant, that with this end in view it is, therefore, most desirable that there should be a uniform standard of medical education and a uniform method of examination for the whole Dominion." Thus it will be seen that our neighbors are wrestling with this question in the hope of securing uniformity of requirement throughout the British realm.

But whilst this is so, and they are to be commended for their laudable efforts in this direction, they deny to the American educated graduate the right to practice in any and all provinces without first undergoing a proper examination. From my standpoint whilst they are to be commended, as perhaps are all other people acting under similar regulations, there is a very trite maxim that applies to this condition with considerable force, "that it is a poor rule that does not work both ways." Now, I would not have Canada, Great Britain, Germany, France or any other country having these regulations and requirements recede one iota, but would rather encourage them to even higher aims, but I would have our own people adopt a similar system, through which foreigners coming, whithersoever they may, will be required to undergo a rigid examination before a national board of examiners, composed in part of the medical bureaus of the United States army and navy and partly of men appointed by the President or Chief of the Board of Education, which board would have its headquarters at Washington, D. C.

Through the operation of such a regulation or law the number who now seek the degree simply for the reason that it is recognized in this country, would be greatly lessened and there would be introduced into the ranks of the profession such only as are thoroughly qualified, to that extent certainly that entitles them to practice in their own country, thus relieving this country of what we are not in need, and measurably reserving our own field for those who are educated here and those from abroad who have passed the necessary examinations at home, and possibly such as may be established here, furnishing a guarantee which will be alike a credit to the profession and a benefit to the people at large. In a word, is it not anomalous for a country to have two grades of qualifications for its medical men, one for home use and the other for exportation: is this not indeed getting down to a commercial basis?

Would it not be well to inject a little of the Monroe doctrine into the medical profession of America as well as into the government? Surely if it be admissible that a Doctor of Medicine can not practice in his own country without a state's examination as in Germany, or that the graduate of the university of one province can not practice his profession in another province, as in Canada, is it not admissible that we should as a great nation, however free in a general sense, establish some regulation by which we may protect ourselves, as against invasion from every nation of the earth, however desirable as citizens they may be (although the majority never become such, but too frequently render themselves offensive through their arrogance whilst living in our midst, and when a fortune is acquired take their gains and return to their own country)?

In every walk of life we find those of the same profession, as the clerical and legal, as well as the trades and mechanics united for the purpose of governing its members, not only in their relations to those not of their own calling but also of each other, thereby tending to elevate themselves in the dignity of manhood and stimulating them to a demand for the right. Why, then, should the medical profession not do the same, particularly as to their relations one to another, and the establishment of proper regulations governing the standard of education, entitling one to enrollment in its ranks, whether he be a foreigner or a

native-born, receiving his training in America or abroad? The code by which we are supposed to be guided makes no such provisions, and I throw out the suggestion that it may be well that it be so amended as to cover these questions.

Without any disposition to contribute to the already generally expressed dissatisfaction growing out of the recent announcement of the twelfth International Medical Congress to be held at Moscow, Russia, in 1897, we can not avoid asking ourselves the reason for restricting its transactions to the French language, or in other words, why it is that the English-speaking people, who perhaps furnish as much support to these Congresses as the rest of the civilized people combined, whether it be in the value of their contribution to the literature of the science or in the lavish expenditure of money amounting too often to recklessness, are overlooked. True, it may be reasoned that the French is more universally spoken, being the court language of Europe. But we answer that 75,000,000 of intelligent people on this continent, furnishing as brilliant minds as can be found within the ranks of the profession in any country of the world, who are through their recognized industry in the direction of investigation constantly enriching the science, are entitled to recognition. Let us trust, since none other than the French language will be considered official, that it may be developed that as many foreigners may be met who speak our language as there will be of English-speaking people who have some knowledge of other languages than their own. Individually I feel that this regulation is but little short of an insult, particularly since, to quote from their announcement, they say: "At the general meeting the addresses *may* be delivered in other European languages." English practically is ignored, and thus public notice is given that we are not wanted.

EMULATIO EMULATIONEM PARIT.

To quote from the post-prandial speech of Dr. J. H. Hollister, of Chicago, on the occasion of the annual dinner of the Gynecological Society of that city on Oct. 18, 1895: "Let no man be over-anxious about his reputation if he intend the right and does his best; ultimately that reputation will take care of itself and of him too." This is true of individuals, true of nations. Great has been the progress of nations during the last 300 years; the development of America in that period has been the phenomenal fact. Cradled without parental care, it came to its estate without the help of other nations: in fact, it grew by reason of their neglect. A noble manhood was its only inheritance. All else is of its own creation. For nearly two centuries we were esteemed a semi-barbarous people by the crowned heads and the elite of Europe, and their prejudices have only been in any measure conquered by our sublime indifference. The struggle to make ourselves a name and a place among the foremost has been indeed severe, but the issue is no longer doubtful. You who have met with this prejudice on foreign shores know well how strong it yet remains; but you know full well that as professional men you have nothing left to fear, and that especially in medicine and surgery Americans have no apology to make. We are to be courteous ever; but deferential or craven, if ever we were, nevermore.

The past year has been no exception to those that have preceded it, in the direction of advancement, invention and discovery; indeed, in some ways it has

eclipsed any of its predecessors. Without enumerating the *many* inventions and discoveries, perhaps the most important is that made by Roentgen of the cathode X rays, or rather their utilization in the direction of surgery. What the possibilities of this discovery and application may be far exceeds the comprehension of man at this time. If but one-half should be realized of what seems possible, it will be ranked as the greatest discovery of the nineteenth century, and the methods of investigation of disease be so simplified and made exact as to seemingly render it positively impossible to make an error in diagnosis. What a blessing to suffering humanity, a boon to the profession.

The claim advanced by Dr. Cyrus Edson of having discovered a cure for tuberculosis, in what he styles asceptolin, is one that naturally attracts attention, and as with the supposed discovery of Koch, will, I should think, be thoroughly tested. Let us hope for better results than were obtained from tuberculin; in this connection it is proper to say that it is to be regretted that men of the character and well-known scientific attainments and honesty of purpose of these should allow a description of what seems to them to be valuable to find its way into the secular press, there to be discussed by unscientific minds before it has been fully experimented with by their authors or others capable of instituting and of observing the results of properly conducted tests. This practice of flying promiscuously into print, whether through the columns of the daily press or medical journals, is fraught with evil, and in defense let be said what may, it savors of commercialism, is undignified and unwarranted and calculated to check investigation on the part of those whose ambition seems above this sordid level, and in so far stay the wheels of progress.

We can easily understand how tempted is the enthusiast, believing he has made so valuable a discovery, as would a cure for consumption be, to herald it to the world, and particularly the profession of which he may be an honored member. We can believe that in so doing he may be actuated by the highest motives, the most exalted sentiments, as holy as those that led the great, lamented Pasteur, who when admonished by his physician of the great danger he was exposing himself to, in spending so much time in a greenhouse where he was pursuing some investigation, replied, "I am in sight of the end, I can not give up my work; come what may I have done my duty." But such men rarely, if ever, promulgate any discovery till its value has been thoroughly established beyond all question. Let us emulate their example in the thoroughness of their work and the caution exercised in the promulgation of it.

The morbid mentality that seems to pervade a large portion of the clerical profession as well as our own, inducing them to endorse every species of proprietary and patent medicines, is a curse that should be stamped out. The clergyman under a conviction that it is his prerogative in looking after the soul to also care for the body, not only presumes to prescribe for the sick man but also to give his official endorsement to every nostrum upon the market without having the knowledge of its composition or the nature of the disease for which he recommends it. This is obviously wrong, productive oft-times of great mischief and is an unwarranted liberty taken with the confidence usually reposed in the clergyman, and an exhibition of meddlesomeness that is totally unjustifiable; surely if

he conscientiously discharges the duties properly attaching to his own profession he will have all he can well do, leaving the investigation of disease and its treatment to those whose profession it is to deal with such matters. This pernicious practice is not limited to the representatives of the church, but extends to the ranks of our own profession. How common it is for medical men, particularly the younger, to attach their names to general recommendations and grant individual certificates setting forth the wonderful results of the employment of certain proprietary medicines! This is less excusable yet, since such certificates carry with them the prestige of professional endorsement; that in itself is a gross violation of the code by which we profess to be governed. I feel that all such violations on the part of members of this ASSOCIATION should be made punishable, at least to the extent of reprimand or perhaps expulsion. Of course, these remarks are intended to apply particularly to the endorsement of such nostrums and proprietary medicines the formulas of which are not published but kept secret, either as to the ingredients or proportion of their component parts.

It has been with inexpressible pleasure that I noticed action had been taken by the ASSOCIATION at its last meeting, together with hearty support from the State Society of Pennsylvania, so far as the advertising columns of our JOURNAL are concerned. We commenced the reform where it should begin, at home, and now let us carry it still further and apply it to individuals. These published certificates are for the most part furnished for the advertising it will give its author, or perhaps the gratification it may bring to see their name in print, either of which is undignified in the extreme and tends to bring the profession to a commercial plane.

Equally gratifying is the effort now being made, asking congress for an additional member of the Cabinet and who shall be known as Secretary of Public Health, and who shall be head of a department, to be known as the Department or Bureau of Health, which shall have a general charge of health matters as well as statistics. Such a department would be of incalculable utility and value, and the measure should by all means possible be pushed forward.

While the year just passed has been marked by several important discoveries of scientific value, the usual advances in the line of medicine and surgery have been made, but I begin to fear that the tendency to push surgery to the exclusion or neglect of medicine is becoming glaringly conspicuous.

It would seem that every tyro imagines that surgery offers the quickest route to success, and that fame is to be attained *only through blood*. Hence every case the symptoms of which are directed to McBurney's point is necessarily a case of appendicitis, for which the only sovereign remedy is the knife; or, if it be a woman, and her suffering is referred to the ovarian region, or she have a fibroma, however small and barren of symptoms of importance, not only must she be subjected to celiotomy at once, but in nine cases out of ten has her uterus, or uterus and ovaries, sacrificed, thus unsexing her without the slightest effort being made to spare these organs, and preserve to the woman her distinguishing function.

If the same practice prevailed to emasculate every man who might have a neurosis of the cord and neighboring organs, there would be fewer operations

than are now done on woman for no greater cause. So common have these operations become of late, owing to the comparative safety through the employment of asepsis attending them, that many women consent to or even apply for them in order that they may avoid bearing children. How far a surgeon may be justified under these circumstances in rendering the desired aid is problematical, whether viewed from either a moral or legal standpoint.

To use the language of another: "We believe thoroughly in allowing the public to estimate the medical profession, but it sometimes seems as though the exploitation of the wonders of surgery was a little overdone, the result being that as soon as a person has any ailment of any part of the body, the people at once want to have it cut out," and, I am sorry to say that this feeling extends to too many of the profession, one saying to me some time ago in consultation: "Why, Doctor, you very well know that all of value in our science is surgery." It is scarcely necessary to say that the author of this remark was an abdominal surgeon, or to put it more directly an abominable surgeon.

That these operations are called for, and loudly demanded by the exigencies of the case occasionally no one can deny; but that they are being done much too frequently I challenge successful contradiction.

The mere fact that the improvements and advancements in surgical procedure make them relatively safe, should not be advanced as an argument, and I look with suspicion upon him who may claim that as no use can be assigned the appendix vermiformis it should upon the slightest provocation or excuse be removed. Is it not time that a halt had been called, and that such cases should be assigned to those who are expert in diagnostic technique as well as surgical procedure? Can any law of either God or man be found to justify oophorectomy or hysterectomy except under the most dire conditions?

Before concluding this very imperfect address, I wish to call attention, in addition to the several questions discussed, to a few serious defects from my standpoint of reasoning in the operations of the Constitution, By-Laws and usage of the ASSOCIATION.

1. There is nothing like the Council of the British and other medical associations, whose duty it is to be in permanent session, or, at least, to meet several times a year, to consider all public questions affecting the welfare of the profession in general and the interests of the AMERICAN MEDICAL ASSOCIATION in particular. At the annual session there is no time for calm deliberation, and consequently there is great danger of hasty and ill-advised legislation, and errors occurring at the moment require a whole year to correct.

2. It appears to me that the ASSOCIATION as a body should not act on any resolution or amendment until it has been carefully revised and recommended by the Council or the Business Committee. In this way we would secure better legislation and prevent the adoption of ambiguously expressed amendments and resolutions.

3. It seems to me that the permanent members of the ASSOCIATION, the conservative element, the men who attend year after year out of love for the ASSOCIATION and the science, and who are the most interested in their welfare should not be thrust into the background and deprived of all voice in the management as at present; it seems the height of absurdity to give

the ballot to the new members, who are unfamiliar with the modes of procedure and know nothing of the policy and tradition of the organization and disfranchise the old ones. (Possibly this may be in a measure overcome by the operation of an amendment introduced at our last meeting should it be adopted.)

4. As regards the place of meeting, I think the action of the nominating committee should be final, as was contemplated in the framing of the constitution wherein a nominating committee was provided for, a part of the duty of that committee was to discuss this question and thus relieve the ASSOCIATION itself of the waste of time and wrangling which this question invariably excites.

5. To me it seems desirable in deciding this question of place meeting that such State or other societies as extend invitations to the ASSOCIATION to meet with them, should be enabled through their representatives to state to the nominating committee the best rates of transportation to said point obtainable, for it is manifestly probable that by making arrangements in advance and getting the roads to bid, as it were, we may secure better terms than by fixing the place first, and making terms afterward.

6. And finally, it is obviously wrong that we should, on taking a vote upon vital questions, have no system or method by which those entitled to the franchise shall be protected in the exercise of it, as against such as are not so entitled. I would suggest as a remedy for the increasing evil that there should be some means of segregation adopted.

And now, one duty only remains, which I would fain avoid, but painful as it is and reluctantly as I approach it, it must be done. It is the sad, sad announcement that like all preceding years this just passed has been no exception, and that our ranks have been greatly reduced by the unrelenting hand of death; many of us here assembled to-day are looking about in the vain hope of meeting some who last year were our companions and co-workers. They are not here! They have passed to the other side and joined the silent majority. The committee on necrology will present a fitting report of such. Meanwhile let us indulge in the hope that their record during life may have been such as to entitle them to that reward which is accorded only to the faithful and just. Let us trust they may be among the elect, and that from on high may be exerting an influence upon our lives that shall be at once ennobling and sanctifying, that we may remember ever that our spirits, like theirs, must return to the God that spake them into existence, and yet:

"It is hard to be parted from those
With whom we forever could dwell;
But bitter, indeed, is the sorrow that flows,
When perhaps we are saying, forever, farewell."

Evidence of Negligent Treatment. A physician and surgeon undertook to treat an injury to the thumb of a man's left hand, and the hand became permanently disabled. For this alleged malpractice, a judgment for \$500 was obtained, which the appellate court of Indiana, affirmed March 3, 1896, in the case of Freeman v. Hutchinson. During the progress of the trial a physician and witness for the plaintiff was permitted, over the defendant's objection, to examine the injured thumb in the presence of the jury, and to exhibit and describe its condition. The appellate court holds that there was no error in this. Not only may a witness use the injured member in giving his testimony, but the court says it is proper for the jury to examine and inspect it. Such evidence is of the highest rank.

ON SOME OF THE LIMITS OF THE ART OF SURGERY.

Delivered at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY N. SENN, M.D., Ph.D., LL.D.

PROFESSOR OF PRACTICE OF SURGERY AND CLINICAL SURGERY IN RUSH MEDICAL COLLEGE; ATTENDING SURGEON PRESBYTERIAN HOSPITAL; SURGEON-IN-CHIEF ST. JOSEPH'S HOSPITAL.

Mr. President and Members of the American Medical Association.—Modern surgery has attained a degree of development which entitles it to the distinction of a science and an art. As a science surgery is of recent date, having been founded and perfected during the last half of the present century. As an art it has been practiced for centuries by our ancestors with credit to themselves and benefit to the injured, the crippled and the sick. When Boyer wrote the introduction to his classic work on surgery he expressed the conviction that surgery had reached perfection. How little did he dream of the great changes that would be wrought in the practice of his cherished profession by the progressive pathologists and surgeons of the next few generations! How innocent and absurd does such a statement appear in the face of the labors of such men as Virchow, Rokitansky, Rindfleisch, Klebs, Recklinghausen, in pathology; Pasteur, Koch, Ogsten, Rosenbach, Baumgarten, in bacteriology; Lister, Langenbeck, Billroth, Hueter, Esmarch, Czerny, Gussenbauer, Nélaton, Verneuil, Terrier, Macewen, Gross, Agnew, in surgery; Terrier, Hitzig, Horsley, in cerebral localization; Spencer, Wells, Keith, Winckel, Martin, Péan, Ségond, Pozzi, Sims, Emmet, Battey, in gynecology, and a host of other faithful unselfish workers who have made surgery what it is to-day and what it is intended to be, the most honored, respected and beneficent branch of the healing art. What a contrast between the standing of the surgeon of to-day in the community, the profession and from a scientific aspect as compared with his colleagues of only a century ago! It is not long since the art of surgery was limited to bleeding, cupping, leeching, setting of a broken limb, reducing a dislocation, stanching hemorrhage, opening an abscess or amputating a limb for injury or disease beyond the reach of conservative measures. He was the subordinate, almost slave, of the pompous, arrogant and self-confident physician of that time. He subsisted from the crumbs that fell from time to time from his master's table. The betterment in the standing and sphere of the members of the surgical craft during the last century is entirely due to the enormous progress that has been made in the science and art of surgery. During this time the legitimate field of medicine has gradually diminished before the advancing columns of progressive and aggressive surgeons. The physician no longer has a monopoly over the diseases of all the internal organs. The physician's distinctive apparel and gold-headed cane of but few years ago no longer intimidate the surgeon; they have disappeared from the scene and the surgeon stands on the same level, if not higher, in every respect with the physician in the eyes of the masses and the estimation of the scientific world. Modern pathology and the new science of bacteriology have laid a permanent foundation for the steady and progressive advance of surgical thought and work. The inflammatory complications of wounds and the etiology of most of the chronic infective surgical diseases have been cleared up by bacteriologic investigations during

the last twenty-five years, and the knowledge thus gained has enabled the surgeon to prevent in a large measure the former and to treat intelligently and with increased success the latter. Many of the most noted surgeons who have left a strong and permanent impression on surgical literature and practice during the last quarter of a century have been enthusiastic and practical bacteriologists and competent pathologists. The wonderful development of operative surgery during the same time is one of the earliest and richest fruits reaped from the vast and fertile field sown and cultivated by bacteriologists of every civilized nation. To the immortal Lister belongs the honor of having opened a systematic and successful crusade against the surgeon's most treacherous enemies—the pathogenic microbes. The great principles which he conceived and introduced into practice created a new era in surgery. Antiseptic surgery is one of the many fruits of his genius and the one, to whom we as a profession and humanity owe more than to any other surgeon dead or living, has been permitted to live long enough to see the creation and blessings of aseptic surgery, the handiwork of his innumerable enthusiastic followers. Antiseptic and aseptic surgery have smoothed the rough and rugged pathway of the practical surgeon. Ordinary cleanliness has given way to surgical cleanliness. The almost universal introduction of antiseptic and aseptic precautions in the treatment of wounds in private and hospital practice has nearly eradicated the three greatest enemies of the surgeon of old, namely, hospital gangrene, erysipelas and secondary hemorrhage, and minimized the occurrence of suppuration and its manifold immediate and remote complications.

No wonder that a sense of security created by such wonderful changes made the surgeons bold. In consequence of such revolutionary changes wrought in the practice of surgery new territories were invaded and organ after organ, the seat of injury or disease, were subjected to direct surgical intervention. Step by step the scalpel found its way into localities where formerly the physician had reigned alone and supreme, and where its presence would have been regarded by him as convincing proof of homicidal intent. No better evidence can be advanced to show the difference in the kind and scope of work of the surgeon of to-day with the one before the pre-antiseptic time than a comparison between the works of operative surgery of now and then. The sense of safety which took possession of the surgeon and an earnest desire to extend his skill to the successful treatment of affections which had heretofore baffled the efforts of the physician, brought on a warfare on almost every organ the seat of real or imaginary disease. The physician found himself suddenly out of his long time honored routine practice. The specialists utilized the opportunity and left no stone unturned to extend their sphere of activity. Brain surgeons, abdominal surgeons, neck surgeons appeared on the scene and filled the medical press with accounts of their wonderful surgical feats. The old-fashioned gynecologist, whose chief occupation consisted in introducing and removing pessaries, cauterizing so-called ulcers of the cervix, swabbing out the uterus and inserting medicated vaginal tampons, became restless and anxious to exchange harmless, bloodless measures for the knife and scissors. His desire for bloody operations was not satisfied by sewing lacerations of the cervix and perineum. He felt that in order to keep abreast with the spirit of the

present age he must increase his range of action, and in due course of time the ovaries, the Fallopian tubes and uterus became the theater of his aggressiveness. Even the acquisition of this additional territory did not satisfy his ambition. The adjoining great abdominal cavity, with its many important organs was looked upon with a jealous eye and it has been made the common camping ground of the general surgeon and the gynecologist for several years.

The throat and nose specialist, under the same influences, became disgusted with his brush, powder-blower and atomizers; sharp spoons, chisels and saws came into requisition, and the number of deflected septa, hypertrophic turbinated bones and third tonsil increased alarmingly and were attacked most energetically. The rectal specialist, who made a modest living by stretching the sphincter and ligating piles, saw a fortune in adding to his limited sphere of activity, resection of the rectum, and later, emboldened by his efforts carried his crusade to the topmost limits of the large intestine. The average orthopedist is no longer satisfied to correct deformities by the use of bloodless manual and mechanical measures; he has acquired a fondness for the knife, saw and chisel, so as not to be left behind in the procession. The genito-urinary surgeon has become tired of treating gonorrhea, strictures and syphilis; he can see no reason why he should not cut for stone, extirpate kidneys and perform plastic operations on the ureters.

The *furor operativus* manifested in these and other special departments of surgery, and its obvious results, render the standing and legitimate scope of the general surgeon very uncertain and indefinite at the present time. Let the general surgeon turn to the right or to the left, advance or retreat and he finds himself on reserved territory. As for the physician, he is expected to answer night calls, prescribe for diarrhea and whooping cough, watch cases of typhoid fever, measles, scarlatina and smallpox, and should complications arise and he does not report to the proper authority he renders himself liable to censure. Much of this ill-applied energy in the surgical world has resulted in detriment to patients and in retarding actual surgical progress. Operative surgery has been carried to extremes. A calm inspection of the ground that has been gone over will show "Some of the Limits of the Art of Surgery," the subject which I have chosen for this address.

Antisepsis and Asepsis. The marvelous reduction in the mortality following injuries and operations which the present generation has witnessed is largely due to the prevention of wound complications by the employment of efficient antiseptic and aseptic precautions. Improved means of hemostasis and the more efficient treatment of shock might reasonably claim a certain share in bringing about such a desirable change in the results of surgical practice, but what has made our work more satisfactory and the statistics of various operative procedures more encouraging is the prevention of infection, the protection of the patient against the immediate and remote effects of sepsis and suppuration. The treatment of wounds with these objects in view has been simplified and rendered more efficient from year to year, but it can not be said that perfection has been reached. We are not yet in possession of an ideal absorbable ligature and suture material. The person who will show us how to prepare the animal ligature and suture in such a way that it will not only be absolutely aseptic but

also antiseptic and without loss of its tensile strength, will be entitled to the lasting gratitude of the entire profession. The disinfection of hands and field of operation is open to future improvement. The important matter of drainage remains in anything but a satisfactory condition and the questions frequently raised, when to drain and how to drain, must be definitely settled by future experience and research. There are surgeons to-day who do not take into account the possible failure of antiseptic and aseptic precautions in estimating the dangers incident to operative procedures. Have we not all heard so-called abdominal surgeons say that an exploratory laparotomy is devoid of danger? Is it not a fact that the abdomen is being opened daily by men who have not the faintest idea of what they may have to do, simply because they regard such a step as harmless and free of danger and the shortest and easiest way to make a diagnosis? To say that such a blind confidence in the efficiency and safety of aseptic precautions is not in accord with the work of the conscientious surgeon is to put it mildly. It is fortunate for the patients of such ever-ready and self-confident operators that the peritoneum under ordinary circumstances can dispose of more pathogenic microbes without harm resulting than any other tissue of the body. If it were not such a serious matter it would be amusing to see how such men explain an occasional death that occurs in their practice in cases where it was least expected. If, perchance, a post-mortem examination was held, the first statement made is that the peritoneum showed no evidences of inflammation, consequently death must have occurred in consequence of shock, exhaustion, bronchitis, edema of the lungs, or heart failure. Very recently a prominent surgeon in giving his testimonial in recommending a certain kind of catgut, made the statement that he had performed one hundred consecutive major operations without having seen a single drop of pus. I have no reason to doubt the veracity of this gentleman's statement, but I am firmly convinced that it would be difficult, if not impossible, to duplicate such an experience in the practice of the average general surgeon.

I have made it a duty on my part to familiarize myself with the advances made in the technique of aseptic surgery and have the good fortune to perform all my operations in two of the best hospitals in Chicago and in a fairly well equipped college clinic, and yet I am only too willing to confess that I never finish my day's work without seeing pus. I have a painful recollection of two amputations for carcinoma of the breast on private patients, in both of which every possible precaution was carried out, and yet to my utmost disappointment, both of them died of the most virulent form of sepsis I ever encountered. To offset these cases I might refer to perhaps over two hundred similar operations in which, under much less rigid precautions, with few exceptions, faultless wound healing was obtained. I remember, too, a case of genu valgum in an adult treated by transcondyloid osteotomy under strict antiseptic precautions, where the operation was followed by violent suppurative osteomyelitis and extensive necrosis which for a long time seriously threatened the limb and life of the patient. I am sure that I am not alone in relating such experiences. Every surgeon is occasionally humiliated by such mishaps and here is the proper place to make open confessions. The careless, reckless remark so often made by men who ought to know better, that

the surgeon who understands his business can make and treat wounds which, if dressed properly, will heal without suppuration, has reached the ears of the legal profession and has already entangled many a worthy and honest member of our profession in the complicated and trying machinery of the law. I envy the surgeon who has implicit confidence in this or that method of preventing wound infection, but I am confident that I but voice the sentiment of the vast majority of surgeons by making the statement that one of the limits of the art of surgery at the present time is the inadequacy of our available resources in furnishing wounds, even under the most favorable circumstances, absolute protection against infection.

Phlegmonous Inflammation.—The employment of antiseptic and aseptic precautions in the treatment of intentional and accidental wounds has greatly diminished the frequency of progressive phlegmonous inflammation and its often disastrous consequences. That such an occurrence can not always be prevented, even by the most scrupulous care and attention to details, every surgeon of experience is willing to admit. In the most virulent forms of phlegmonous inflammation the most heroic and timely treatment, local and general, is often fruitless in averting speedy death. In the most desperate cases the surface lesion is often insignificant, the infection following the lymphatic pathways, soon reaches the general circulation resulting in death from acute sepsis before any decided gross pathologic lesions have appeared at the seat of infection or in any of the internal organs. How rapidly general infection may take place has been shown by the experiments of Schimmelbusch, who found microorganisms in the spleen five to ten minutes after infection of a wound. Colin and Niessen demonstrated by their experimental work that amputation a few minutes after inoculation, of the ears and limbs of rabbits with pure cultures of anthrax, did not protect the animals against generalization of the disease. Such cases in the human being fortunately are seldom met with, but when they do occur, the art of surgery is powerless in arresting the progress of the disease. Parenchymatous injections of solutions of carbolic acid or corrosive sublimate along the course of the inflamed lymphatics, and the internal use of alcohol in heroic doses promise the most, but in the great majority of cases the extension of the infection continues and terminates speedily in death from general sepsis. Whether bacteriology will furnish us with a more potent weapon in the treatment of such cases the future must determine. When the infection has resulted in suppuration the old adage *ubi pus ibi incisio* remains as true to-day as before the microbic origin of pus was known. In the treatment of diffuse phlegmonous processes it is now customary to make free incisions, establish free drainage and disinfect the cavity by flushing it freely with a safe and yet efficient antiseptic solution, such as a saturated solution of acetate of aluminum, a 3 per cent. solution of carbolic acid or a 1:5,000 solution of corrosive sublimate and apply to the part hot compresses wrung out of the same solution. A few years ago Helferich advised laying open of the entire cavity by a single incision, recently Kocher pleads in favor of small incisions for the reason that pus microbes multiply more rapidly when freely supplied with oxygen. I believe the best treatment is half way between these two extremes, that is, multiple incisions large enough to insert drains the size of the little finger with a view

of establishing a perfect system of drainage. We can not expect much from a single disinfection. In severe cases in which life is threatened by sepsis I invariably resort to continuous irrigation with a saturated solution of acetate of aluminum, a non-toxic and yet very efficient antiseptic agent. The inflamed part should be immobilized and maintained in an elevated position until the inflammatory edema has subsided. The same treatment yields the most happy results in the treatment of acute suppurative inflammation of the large joints. One of the great shortcomings of the art of surgery to-day is the lack of measures to deal more efficiently with progressive suppurative affections and secure for suppurative cavities an aseptic condition in a shorter and more direct way. In cases of circumscribed abscesses it is generally believed that the sooner the incision is made the more prompt will be the relief and the more speedy the cure. Clinical experience has not confirmed these expectations. The old surgeons applied emollient poultices until the abscess became soft before they used the bistoury. No modern surgeon has any use for the filthy germ-breeding poultice, for which he has substituted the antiseptic, moist, hot compress which answers the same purpose, as it furnishes the necessary heat and moisture, and at the same time prepares the surface for the incision. We are, however, almost as powerless as our forefathers in limiting, much less aborting, a suppurative inflammation. One of the greatest and most useful innovations in surgery would be a remedy, local or general, which would enable us to abort the process of destruction after the classical symptoms which characterize suppurative inflammation have set in. We must look to bacteriology to fill up this most important gap.

Acute Suppurative Osteomyelitis.—Closely allied to phlegmonous inflammation of the soft tissues is acute suppurative osteomyelitis as it is caused by the same kind of microbes and results in more or less extensive destruction of tissue. The etiology and pathology of this disease are now well understood and upon them is based the early operative treatment which is generally endorsed by the profession at the present time. The danger from general sepsis is greater in the more serious forms of osteomyelitis than a similar affection of the soft tissues owing to the location of the primary focus of infection and the frequency with which the adjacent large joints become implicated during the progress of the disease. The early removal of the osteomyelitic product by operative interference as a rule relieves pain promptly, limits necrosis, guards against joint complications and minimizes the danger from general sepsis. Immobilization of the affected limb in proper position and the exposure of the osteomyelitic focus by the use of the chisel or gouge as soon as a positive diagnosis can be made are the modern resources which have succeeded in greatly reducing the mortality of this disease as well as its immediate complications and remote consequences. There are, however, cases of acute osteomyelitis in which the earliest intervention of the art of surgery is powerless in preventing death from general sepsis. These are the cases of osteomyelitis in which simultaneously or in rapid succession a number of the long bones become involved and where the local signs and symptoms are overshadowed by the general symptoms which point to a progressive sepsis and which are so seldom favorably influenced by either local or general treatment.

Tuberculosis of Joints.—Only a few years ago the surgeons who paid special attention to diseases of the joints were enthusiastic advocates of early resection or arthrectomy in cases of tubercular joint affections. Typical resections were made regardless of the anatomical location or the extent of the disease. It was believed that such medical treatment would succeed in eliminating the local affection and in preventing the extension of the infection to distant organs by reinfection from the peripheral focus. Statistics prove that these hopes are unfounded and conscientious and thinking surgeons have substituted largely in place of operative treatment conservative measures. The surgeon forgets too often that tuberculosis of joints seldom appears as a primary affection but as a rule appears as a peripheral manifestation of the existence of an antecedent perhaps undiscoverable tubercular affection of another organ, hence the removal of the accessible tubercular product does not necessarily protect the patient against tuberculosis of other joints or organs or general miliary tuberculosis. It is on the other hand a familiar clinical fact that the operative treatment of joint tuberculosis has not infrequently been followed by tuberculosis of other organs or general miliary tuberculosis. The short-comings of the art of surgery are well brought forward in the treatment of tubercular joints. In large clinics where but a few years ago resection of joints for tuberculosis was a daily occurrence such operations are now rarely witnessed. This change in practice is largely due to the beneficial effects obtained from intra-articular and parenchymatous injections of iodoform glycerin injections. I have resorted to this treatment in hundreds of cases with the most satisfactory results. In about one-half or two-thirds of all cases of uncomplicated joint tuberculosis this treatment proves curative. It is of special value in the treatment of tubercular abscesses in communication with a tubercular joint or bone. From one to three or four injections usually suffice in obliterating the abscess cavity. The tapping and injection must be done under the strictest antiseptic precautions lest the operation will aggravate the case, perhaps render it hopeless, by becoming the direct cause of a mixed infection with pus microbes. As some persons are peculiarly susceptible to the toxic action of iodoform the minimum dose two drachms of a 10 per cent. emulsion should be used in the beginning. In cases complicated by renal affections this caution should be increased as any affection of the kidneys retards the elimination of the iodoform and thus increases the danger from intoxication. Another important precaution in tapping a tubercular abscess is not to puncture the skin where it is thin and cyanotic as when it is made in such a place the puncture is very liable to give rise to a fistulous opening and consequently increased risk of infection with pyogenic microbes. The puncture must be made through normal skin, if need be some distance from the abscess, and after removal of the canula it should be sealed with iodoform collodium and a small pledget of sterile cotton. Immobilization of the limb or part thus treated is often useful but not always necessary. During the process of repair initiated by the iodoform injections the capsule of the joint often undergoes great contraction which if not counteracted by an appropriate mechanical support may result in a deformity difficult of correction short of operative interference. In cases of joint tuberculosis in which this treatment does not succeed in effecting

a cure it will prove to be the best possible preliminary treatment to a successful arthrectomy or atypical resection. Iodoform is absolutely useless in the treatment of tubercular affections complicated by suppuration. The antibacillary effect of iodoform in such cases only asserts itself after the pyogenic product and its causes have been eliminated by operative measures or chemical disinfectants or by a combination of these two antiseptic resources. In cases in which the iodoform treatment fails or in which it is contraindicated, arthrectomy and atypical resection have been largely substituted for typical resection.

Malignant Tumors.—The imperfections of the art of surgery become very apparent in the treatment of far-advanced malignant disease of any part or organ. The essential cause of carcinoma and sarcoma remains to be discovered. The science of surgery must first divulge the true nature of tumors before we can expect a decided advance in their more successful treatment. The essential features of the modern treatment of malignant tumors may be summed up very briefly as follows: Operate early and thoroughly. The treatment of unoperable sarcoma by injections of the sterilized toxins of the streptococcus of erysipelas and the bacillus prodigiosus has not filled the expected results. In my paper on this subject read in the Surgical Section of this Association at the last meeting I gave the results of my experience with this treatment. An additional experience since that time only confirms my views expressed at that time concerning the utter lack of curative power of these toxins in the treatment of genuine cases of sarcoma. The microscope is no infallible means of diagnosis in differentiating between small round celled sarcoma and some of the granulomata. The curative effect of a remedy can not be established unless an absolutely correct diagnosis can be made of the disease in the treatment of which it is employed. The discovery of some remedy, which by its local or general action would correct erratic cell growth and transform embryonic into mature cells might possibly change malignant into benign tumors and by doing so deprive them of their malignant clinical tendencies. Experimental researches in this direction might possibly lead to a rational treatment of malignant tumors short of a resort to the knife or caustics. At the present time the surgeon's resources in the treatment of malignant tumors are largely limited to an early and thorough use of the knife. Every surgeon deplors the fact that with the exception of carcinoma of the lip or of parts similarly exposed the patients who apply to him for surgical treatment with few exceptions are suffering from malignant tumors which extend beyond the organ primarily affected and have given rise to regional dissemination, general metastasis or both. For instance, of the over 200 cases of carcinoma of the breast which have come under my own observation I remember only one case in which during the operation, the axillary glands were found unaffected and in this case the columnar celled carcinoma, the size of a pea, had obstructed a duct, in consequence of which a retention cyst the size of a walnut developed, for which the patient applied for treatment. In cases of carcinoma of the uterus that come to me for examination and treatment, I find that only one out of every eight or ten cases is a proper case for a radical operation. In more than one-half of my cases of carcinoma of the rectum I refuse extirpation of the affected organ, and advise in its place an inguinal colostomy, because the disease has extended.

to the pelvic connective tissue, the retro-peritoneal lymphatic glands or adjacent organs. Of eighteen cases of pyloric carcinoma of the stomach subjected to operative treatment, I found the disease limited to the part primarily affected only in one case; in the remaining cases the disease had extended invariably to the lymphatic glands, and in some of them to the adjacent organs, liver, gall-bladder, pancreas, omentum and colon. It is the operative treatment of advanced cases of malignant disease that brings so little benefit to the patient and so much disappointment to the surgeon. Asepsis and a greatly improved operative technique have done much to improve the results of operative treatment of malignant tumors, but they have not succeeded in doing away with well recognized restrictions upon the art of surgery to which I now desire to call your attention. There is perhaps, no other department in surgery which presents more diversity of opinions than the selection of cases of malignant tumors for operative treatment.

The conscientious surgeon looks as carefully for contraindications as for indications for radical operations. He is concerned more for the welfare of his patient than his own selfish interests. A prospective liberal fee has no influence in changing his decision. He makes a careful examination of his patient, the tumor and its environments, before he recommends an operation. He has learned from sad experience that aside from justifiable palliative operations for obstructive malignant affections, imperfect operations have proved as detrimental to his patients as to his reputation. He looks the ground over carefully before he decides to attempt a radical operation. The squeezing out of a fixed carcinomatous uterus between forcipressure forceps is not likely to prolong the life of the patient or increase the reputation of the surgeon who ignores to such an extent the limits of the art of surgery. The removal of a carcinomatous breast without a thorough clearing out of the axillary space may increase for the time being the bank account of the operator, but it will surely prove a detriment to the patient. The partial or complete excision of the rectum for carcinoma complicated by regional infection is an operation attended by great immediate risk to life without a ray of hope of effecting a permanent cure. Such bold and reckless overstepping of the limits of the art of surgery is not calculated to increase the estimation of our profession in the eyes of the public or to receive the sanction of the conscientious, discriminating surgeon. The radical removal of a malignant tumor means more than the extirpation of the primary tumor; it means the removal of every malignant cell, whether in the immediate vicinity of the primary growth or in the same region. Evidences of distant metastasis furnish a positive contraindication to operative interference. Regional dissemination beyond the reach of complete removal of every vestige of tumor tissue, local and regional, without imminent risk to life, constitutes an equally forcible argument against a radical operation. Large surface defects made by extensive radical operations should always be covered by a plastic operation or by Thiersch's method of skin grafting. It has always been my aim to cover the wound with skin by either of these methods immediately after the extirpation of the tumor for the purpose of securing healing by the first intention, as I am satisfied that the slow process of healing of large surface defects

by granulation, cicatrization and epidermization is conducive to an early local recurrence.

Surgery of the Three Great Cavities.—The systematic invasion of the three great cavities of the body for the treatment of injury or disease is one of the great triumphs of modern surgery. Our ancestors entertained a well-founded dread for operations which necessitated opening of any of the great serous cavities, knowing from experience their great susceptibility to septic infection. Recent experience has shown that any of these cavities can be opened for diagnostic or therapeutic purposes without much danger provided the operation is performed under strict antiseptic precautions. The prevention of septic complications by asepsis has been the means of creating visceral surgery. The sense of safety in subjecting the different viscera to direct operative treatment which has taken possession of the profession has enlarged to a wonderful extent the field of operative surgery, but it has carried at the same time the work of the ambitious enthusiastic surgeon beyond the limits of his art. Many of the bold attempts upon the organs of the three great cavities are far beyond the legitimate restrictions established by the science of surgery. The mania for achieving new victories outside of the sphere of legitimate rational surgery has neither brought lasting reputation to the adventurers nor benefit to suffering humanity. Many of the new operative procedures remind one more of sensationalism than the product of mature, deep surgical reasoning. The accounts of new operations that are being constantly devised have left operative surgery in a state of confusion. Works on operative surgery that left the press six months ago are obsolete or at least unsatisfactory to-day. The technique of nearly every operation is constantly undergoing changes by the addition of important or unessential modifications. Nearly every surgeon has a flaming desire to connect his name with an instrument of his invention, a new operation or a modification of an old one. A new operation is devised, a case is found upon which it is tried, and if the result is in any way favorable an account of it is sure to find its way promptly into the current medical literature. Many members of the medical profession are willing and ready imitators, who are always anxiously waiting for new discoveries and improvements, ever ready to apply them in their practice without questioning their utility or justifiability. This blind imitation of the practice of others has been the source of great harm to confiding patients and has exerted a powerful inhibitory effect on the true progress of surgery. This is an age of bold surgery. The surgeon who is careful in the selection of his cases, slow and painstaking in his work, need not look for recognition on the part of his students or colleagues; it is the man who lays the abdomen open by a single stroke of his knife, removes two healthy ovaries and closes the incision and returns his patient to her room in seven minutes, who commands the attention of his audience and bears with a self-confident dignity the proud distinction of being a bold and brilliant operator. In calling your attention to the limits of the art of surgery in the treatment of injuries and diseases of the organs contained in the three great cavities, time will only permit to point out a few of the most flagrant transgressions of the established principles of surgery during the last few years.

Surgery of the Skull and Brain.—The use of the

trephine in the treatment of fractures of the skull has had a varied experience since the time of Hippocrates. Trephining of the skull for injuries is one of the oldest operations in surgery. From time to time strong arguments have been made against the indiscriminate operating for fractures of the skull. Stromeyer and his followers abandoned the operation of trephining, believing and claiming that the operation resulted in more harm than good to the patient. It is not difficult to conceive that at that time the conversion of a subcutaneous into an open fracture was attended by great risks from infection. The minimizing of the danger from infection by aseptic precautions again brought the trephine into general use not only in the treatment of fractures of the skull, but also in the treatment of pathologic intracranial lesions of a non-traumatic origin. Many surgeons now advocate trephining in all fractures of the cranial vault, claiming that the operation would reduce to a minimum the dangers from remote complications such as obstinate headache, epilepsy and insanity. The question arises, is such a position in consonance with rational surgery? Every surgeon knows that such remote complications after fracture of the skull not subjected to trephining are rather the exception than the rule. It is evident that operative interference in such cases has been carried to extremes. Even under the protection of aseptic precautions, the transformation of a closed into an open fracture of the skull is attended by certain risks which no surgeon can afford to ignore and which must be taken into careful consideration before operative interference is determined upon. This advice applies with special force to the treatment of fractures of the skull in children, as in them spontaneous elevation of the depressed fragment or fragments is frequently observed during the process of repair. There is no rule in surgery without its exceptions, hence the advice to use the trephine in fractures of the skull with depression without regard to the age of the patient or the presence or absence of symptoms, lacks a moral as well as a scientific foundation. The art of surgery has its well-founded limits in the treatment of fractures of the skull. In my opinion, operative interference is absolutely indicated in fractures of the cranial vault under the following circumstances: 1. All open fractures, including gunshot and punctured fractures. 2. Depressed fractures attended by well defined symptoms caused either by the depression or intracranial complications. 3. Rupture of the middle meningeal artery with or without fracture of the skull. The use of the chisel or trephine is superfluous and often harmful in the treatment of subcutaneous fractures of the vault of the skull with or without depression, more especially in the case of children. The operation of trephining in the prevention of remote complications of fracture of the skull is often powerless, owing to the existence of visceral lesions which it can neither remove nor render harmless. The indiscriminate use of the chisel and the trephine in the hands of the inexperienced practitioner is fraught with danger and should not be encouraged by teachers and expert surgeons. Such teachings and practice are in conflict with the correct principles which should govern the true art of surgery. Brain surgery is of recent origin. It is in this department of the operative work of the surgeon that art has gone far in advance of the science of surgery. Cerebral localization and aseptic surgery have made it possible to treat a few intracranial lesions successfully

by direct operative interference. Cerebral localization is in its infancy, and the minutest aseptic precautions do not absolutely protect against infection. A few years ago the columns of the medical press brought glowing accounts of the removal of brain tumors. Patients were exhibited at the meetings of different medical societies with enormous cranial defects and ghastly depressions marking the place from whence a large glioma had been removed successfully. Such cases aroused the most intense attention and interest at the time, but where are they now? Subsequent reports failed to appear, and an ominous silence remains regarding their ultimate fate. Many of the cases of tumor of the brain operated upon who never recovered from the immediate effects of the operation were never reported, and those who were fortunate enough to survive the fearful ordeal, after a longer or shorter interval joined the silent majority. One of the well defined limits of the art of surgery is the operative treatment of malignant tumors of the brain. Tapping and drainage of the lateral ventricles as taught and practiced by Dr. W. W. Keen, may and undoubtedly will become in the future a useful and legitimate surgical resource in the treatment of inflammatory affections of that part of the brain, but so far it has not yielded encouraging results. When Lannelongue devised linear craniotomy for the liberation of the undeveloped imprisoned brain in the skull of infantile idiots, his doctrine was received with open arms by many surgeons who occupy the front rank in the profession. The lay and medical press vied with each other in bringing before the general and medical public the wonderful results following the use of the trephine, chisel and rongeur forceps in opening the skulls of such unfortunate children. Many of these little innocents of course succumbed to the immediate effects of the operation, but this did not subdue the ardor of the surgeon, as he had been instrumental in transferring an object of pity to that happy home where microcephalus is unknown and had relieved the family of a troublesome trust. Where are the cases that have been permanently benefited by the operation? Ask Lannelongue whether his hopes have been realized. I am free to confess that I have never been able to muster my courage to attack the skull of a poor, innocent and yet happy microcephalic child, because I have always regarded the operation as useless in promoting brain development. The responsibility of the surgeon is not limited by the defective mental development of the child nor the importunity of the parents in demanding the operation at all hazards. The surgeon should stand guardian over such a charge, mindful of the limits of the art of surgery. Have we a right to estimate human happiness? The driveling idiot has many enjoyments and pleasures that you and I know nothing about. His responsibilities to God and man are limited and his existence on earth is a long, happy dream, which only ceases when the soul leaves the imperfect body and returns from whence it came, where mental distinction is unknown. The operative removal of inflammatory products from the cranial cavity and the brain has yielded the most satisfactory results, and constitutes one of the most important achievements of modern surgery. This part of cerebral surgery will reach perfection with the progress of cerebral localization, and should be encouraged and cultivated by all who are desirous of extending the present limits of the art of surgery.

Surgery of the Chest.—Modern surgery has done much toward the alleviation and cure of injuries and diseases of the organs of the chest, but it is here also that we are confronted by well defined limitations of the art of surgery. The successful treatment of hydrothorax and empyema of the pleural cavity is the result of a better knowledge of their etiology and pathology and an improved operative technique under strict aseptic precautions. Tapping of the chest for tubercular hydrops followed by iodoform glycerin injection has done more for this class of patients than counter irritation and the internal administration of digitalis, squills, acetate and iodid of potassium. Free incision of the empyemic pleural cavity after resection of one or more ribs, followed by efficient tubular drainage, has become an established practice by almost universal consent. The treatment of chronic empyema with thickened pleura and collapsed adherent lung by Estlander's multiple rib resection or Schede's thoracoplastic operation has yielded brilliant results. The treatment of abscess of the lung by rib resection, free incision with the knife point of the Paquelin cautery and tubular drainage has been the means of saving many a precious life, which, without the aid of the surgeon would have been doomed to a premature death. With few exceptions this is about all that has been accomplished by the surgery of the chest. It is true that a few surgeons have been fortunate enough to cope successfully with a few affections of the heart and its serous investment, the pericardium. Tapping of the pericardium for serous effusion has become one of the established operations in surgery. A very few cases of pyopericardium have been brought to a successful termination by free incision and drainage. We are familiar with isolated cases in which bold surgeons exposed the heart by a free incision for the removal of a foreign body, or sutured a visceral wound, and their effort was crowned by success, but on the whole we are painfully conscious of the fact that the art of surgery has done very little toward the successful treatment of injuries and diseases of this organ. Many have been the efforts of surgeons to supplant the physician in the treatment of pulmonary tuberculosis, the results of such efforts are familiar to you all. In the very nature of things, such trespassing upon the legitimate field of the physician has been followed without exception, by an ignominious failure. It is unfortunate, but true, that the surgical treatment of pulmonary tuberculosis by direct surgical intervention is beyond the present legitimate limits of the art of surgery. Surgery has done very little during the last two decades toward a betterment of the treatment of penetrating stab and gunshot wounds of the chest. The careful surgeon knows that the hermetic sealing under aseptic precautions of the wound of entrance and exit, if such exists, affords the greatest degree of safety in arresting hemorrhage and in preventing septic complications. Free incision of the cavity of the chest with a view of arresting hemorrhage by ligature, or tamponade from any of the organs which it contains is attended by such great immediate risks to life that the possible benefits to be derived from it are more than overbalanced by the immediate dangers which attend such an aggressive course of treatment. The removal of malignant tumors of any of the organs of the chest is beyond the present limits of the art of surgery.

Surgery of the Abdomen.—For reasons that do not

require an explanation here the abdominal cavity was largely a *terra incognita* to the surgeon of less than half a century ago. To-day it is the favorite battleground of the average surgeon and the select field of the so-called abdominal surgeon.

The bold surgery of to-day upon the organs of the abdominal cavity is largely due to the comparative safety with which the peritoneal cavity can be invaded under proper aseptic precautions. This new field for the display of surgical talent and ingenuity has been diligently cultivated in a legitimate way by the honest progressive surgeon, but it has also been made the playground of unscientific sensational surgery by men who are ignorant of the legitimate limits of the art of surgery. The simple fact that any of the abdominal organs, in part or in whole, can be removed successfully without much danger to life does not establish the legitimacy of the surgical procedure. Billroth, one of the greatest, and certainly one of the most honest surgeons of this age, did not realize the expectations he entertained in regard to the benefits to be derived from direct surgical intervention in cases of carcinoma of the stomach, justifying surgical interference. Notwithstanding the wonderful improvements in the technique of operations upon the stomach, partial gastrectomy and pylorotomy have yielded anything but encouraging results. In nearly 50 per cent. the patients subjected to radical treatment for malignant disease of the stomach, succumbed to the immediate effects of the operation. In all of the cases which survived the operative ordeal, the patients succumbed to a relapse in from a few months to several years. I have opened the abdominal cavity for the surgical treatment of malignant disease of the stomach nineteen times, and only in one case did I find the disease limited to the organ primarily affected and in this case the general health of the patient had been so much deteriorated by the obstructive pyloric carcinoma as to contraindicate a radical operation, in all of the remaining patients a pylorotomy or partial gastrectomy was out of the question, as the carcinoma of the pylorus or stomach had extended to adjacent organs or had given rise to regional infection through the lymphatic glands sufficiently to contraindicate any attempts at radical removal of the disease. The legitimate limits of the art of surgery in the treatment of malignant disease of the stomach embrace the cases in which a sufficiently early diagnosis can be made when the malignant disease is limited to the organ primarily involved and the strength of the patient is adequate to overcome the immediate effects of the operation. The removal of the carcinomatous pylorus or any part of the stomach after the malignant disease has extended to adjacent organs or after regional infection through the lymphatic glands and channels has taken place is tampering with the present limits of the art of surgery. The palliative operations for carcinoma of the cardiac and pyloric extremities of the stomach have yielded excellent results, and should receive the sanction of every surgeon who has the best interests of his patients at heart. Witzel's operation for establishing an external gastric fistula in cases of malignant obstructive tumors at the cardiac orifice of the stomach, and Rockwitz-Wölfler's operation for pyloric carcinoma are the palliative operations which promise the most with the least immediate risks to life in all cases of malignant tumors of the stomach which give rise to obstruction. The treatment of intestinal obstruction by surgical inter-

vention has become an established custom. Physicians and surgeons imbued with a proper moral and scientific sense, recognize the importance of early surgical interference in all cases of intestinal obstruction due to mechanical causes. An early positive diagnosis is an essential prerequisite to success in such cases which must be followed by prompt action on the part of the surgeon. Intestinal surgery will celebrate its greatest triumphs with the progressive development of our diagnostic resources in the early recognition of the nature and location of the mechanical causes which give rise to intestinal obstruction. Volvulus and invagination, some of the most serious forms of mechanical obstruction, if they could be recognized within a few hours of their appearance and subjected to surgical treatment at once, would no longer figure so conspicuously in our mortality reports. The division or excision of a constricting band in the treatment of intestinal obstruction from such a source, if performed in time would yield a very small mortality, but if not brought within the present limits of the art of surgery, such cases seldom recover from the immediate effects of the operation.

The radical treatment of malignant tumors of the intestinal canal has not been attended by satisfactory results as a rule. In the majority of cases the operations were postponed until the malignant disease gave rise to symptoms of obstruction, when it was usually found that the carcinoma had passed beyond the legitimate limits of a radical operation. The implication of adjacent organs and extension to the lymphatic glands of the mesentery must be recognized at the present time as positive contraindications to a radical operation. With few exceptions the transgression of this rule in cases in which the patients survived the immediate effects of the operation was followed by an early recurrence of the disease to which the patient rapidly succumbed. Palliative operations in cases of malignant obstruction of the intestinal canal above the rectum, by establishing an anastomotic opening between the intestine above and below the obstruction, have become recognized procedures in surgery. In establishing such a communicating opening, the employment of mechanical devices, such as the metallic buttons of Murphy, Ramangé and Chaput, which must pass the intestinal canal unchanged, is a procedure fraught with more or less danger, which is being recognized more as the experience with them increases. In my own practice I have largely dispensed with the perforated decalcified bone-plates and now rely more frequently on the needle and thread in performing such operations and the mass of the profession is in accord with this practice. The custom followed by many American surgeons to remove the appendix in all cases in which a diagnosis of appendicitis is made, is a very harmful one. The removal of the appendix should be limited to those cases in which, during the first attack symptoms arise which portend danger to life and relapsing appendicitis. Some cases of appendicitis yield to medical treatment, and in a large percentage of such cases the patients remain free from a second attack. Pancreatic surgery at the present time is limited to the treatment of cysts by establishing and maintaining an abdominal fistula until the cyst becomes obliterated. The extirpation of pancreatic cysts and partial pancreatectomy for malignant disease are operations fraught with danger and do not come within the legitimate limits of the art of surgery at the present time.

Much has been done of late in the way of developing and enlarging the sphere of the surgery of the liver and the biliary tracts. Recent clinical experience and the results of experimental research have shown that a considerable portion of the liver can be removed for injury or disease with a fair expectation of success. The treatment of gunshot and stab wounds of the liver by laparotomy and suturing or tamponing of the visceral wound has yielded encouraging results. A number of successful cases of excision of isolated adenomatous tumors of the liver have enriched and graced our modern surgical literature. The operative removal of malignant tumors of the liver is an undertaking far beyond the present limits of the art of surgery. The successful treatment of abscess of the liver and echinococcus cysts by direct surgical intervention is generally recognized as one of the greatest achievements of abdominal surgery. The pioneer work of Sims and Kocher in laying the foundation for a rational treatment of impacted gallstones in any part of the biliary tracts has yielded unexpected results and has been the means of saving thousands of lives by averting the dangers from perforation and cholemia by a timely surgical intervention. The removal of calculi from the gall bladder can now be accomplished with very little danger to life. The cystic and common duct the seat of an impacted calculus are now exposed and incised, the calculus extracted and the wound sutured or drained, with a well-founded hope that the patient will recover, and that the operation will result in restoring the free flow of bile through the biliary passages. I have reason to believe, however, that the surgery of the biliary passages has been carried too far. That unnecessary operations have been performed upon the gall bladder and the biliary ducts, no one will deny. The simple fact that a patient is suffering from gallstones does not furnish a positive indication for surgical interference. The physician and nature's resources should be given a chance and the surgeon's services should be limited to those cases in which positive indications for operative treatment present themselves. The surgeon who recorded the first successful case of cholecystotomy has since become the victim of gallstones, but instead of calling upon one of his colleagues to open the gall bladder and remove the stones, he made a pilgrimage to Carlsbad and was promptly relieved of his sufferings. Cholecystenterostomy should only be performed in cases in which the common bile duct is permanently occluded by an impacted irremovable gallstone or cicatricial stenosis. Catheterization of the cystic and common bile ducts preceded or followed by dilatation by the use of laminaria tents in the treatment of impacted stones and cicatricial stenosis after the formation of a gall bladder fistula is a much neglected part of the surgery of the biliary passages and of sufficient importance to invite new trials and investigations. For substantial reasons abdominal nephrectomy and nephrotomy have been supplanted by lumbar operations. The treatment of tubercular hydrops of the peritoneum by incision, drainage and iodoformization remains in favor with the profession, and continues to yield the most satisfactory results.

Organs of Generation.—The greatest onslaught of modern surgery has been upon the organs of generation, male and female. It is somewhat strange that the organs created for distinguishing the sex and for the increase of the human species should have been

singled out as innocent objects of so-called modern aggressive surgery. The future historians who will record the work of many gynecologists belonging to the present generation will have reason to express their surprise at what disasters the art of surgery has produced when plied in cases far in advance of a scientific foundation. Here and there we hear a feeble voice protesting against the indiscriminate surgery upon the organs of generation of the opposite sex, but the mutilating work continues in spite of such opposition and well-meant advice. Every competent and honest gynecologist knows that in his sphere the art of surgery has been thoroughly abused. It is difficult to assign tangible reasons for such a fearful state of things. It appears to belong to the spirit of the present generation, the outcome of ceaseless unrest in pelvic surgery. When I arraign the gynecologists before this body composed of representative medical men of this country for innumerable and inexcusable transgressions of the rules which ought to govern and control the art of surgery, I do not include the scientific, honest, conscientious workers in that department of surgery, but my remarks will apply to a class of routine operators which has recently grown to alarming dimensions not only in this but in nearly every country which has been penetrated by the dim rays of so-called bold surgery. It is a subject that I would gladly pass over in silence, but you have imposed upon me a trust which I can not ignore and I stand here in the capacity of the conservative element in these days of wild, unfounded surgery to place myself on record in protesting against the unnecessary mutilation of the sexual organs of either sex, willing to stand or fall by the sentiments of the great mass of general practitioners, which after all must be regarded as the backbone and final tribunal of our profession. The new generation of doctors finds no longer satisfaction in practicing their profession in some rural district. The young practitioners have their eyes on large cities and have heard of enticing fees paid to specialists for insignificant operations. Why buy a horse and saddlebags when a fortune awaits them in devoting themselves to a specialty, more particularly gynecology? The recent graduate or the man who has become disgusted with country practice seeks a much employed gynecologist, follows his work for a month or two and returns to his prospective field of labor a full-fledged specialist. He is now ready to extirpate the uterus, remove ovaries and Fallopian tubes, sew imaginary lacerations of the cervix and perineum. Do you suppose that such an aspirant for gynecologic fame ever examines a woman and finds her perfect? Is it not true that in nine out of ten cases he finds something to mend? That my views are real and not visionary let me relate a few instances. A number of years ago a young lady accompanied by her grandmother applied to me for treatment for a neurasthenic affection. I was informed by the grandmother that a few days before they had consulted a young gynecologist, who made a hasty vaginal examination, looked wise and informed them that he had found the source of all trouble in the form of a laceration of the cervix, which would require an operation. As a matter of course the grandmother asked for an explanation of the injury and was promptly informed that it was one of the common accidents of childbirth. As the patient was unmarried and had never been pregnant this explanation proved unsatisfactory to the interested parties and no arrangements were made for

the prospective trachelorrhaphy—upon a virgin uterus. Not long ago an unmarried woman came under my care who had been told by an ambitious gynecologist that she was suffering from a myoma of the uterus which would necessitate a vaginal hysterectomy. I found a sharp antelexion, the anterior wall of the uterus being prominent and somewhat edematous had been mistaken for a tumor and nothing short of a hysterectomy would satisfy the operator. This patient recovered under conservative treatment without the loss of an important organ. The cases which I have just cited escaped mutilating operations by doubting the diagnosis of those to whom they first applied for treatment; others are less fortunate. Suffering woman will believe in and submit to almost everything. In fact it has become almost a fashion for women suffering from real or imaginary affections of the genital organs to consult a gynecologist as regularly as her dentist or dressmaker. Not long ago a girl 18 years of age was brought to me with the information that she became epileptic when 7 years of age, that later, when menstruation was established, the attacks never occurred during the menstrual period, and yet both of her ovaries were removed by a gynecologist. As could be expected, the epilepsy remained and when I saw her she was on the verge of insanity. Time does not permit to cite additional illustrations showing criminal trespass upon the legitimate limits of the art of surgery in the treatment of real or imaginary ailments of the female organs of generation. Every practitioner has seen such instances as I have cited above. Has humanity been the gainer since the gynecologists became surgeons? This is a timely and serious question. Is the average woman who has passed through the hands of one or more gynecologists physically and mentally in a better condition than our mothers of fifty years ago, whose ovaries were safe and who knew but little about speculums and vaginal douches? Let the older members of our Association answer this question. When the venerable and distinguished Emmet devised his operation for laceration of the cervix he pointed out clearly what conditions called for and were benefited by trachelorrhaphy. The operation was received with enthusiasm and everyone present here knows how much it has been misapplied. It is safe to assert that not one in ten cases that have been operated upon was the operation justifiable or proved of any benefit to the patient. Emmet's teachings and practice were in consonance with sound pathologic principles but hundreds of imitators were less discriminating in the selection of cases, and performed the operation simply because they found a laceration of the cervix, irrespective of the existence of symptoms which could be referred to this condition. Laceration of the perineum is another favorite subject of the "amateur" gynecologist. The extent of laceration and the symptoms caused by it are not always taken into careful consideration in deciding upon the propriety of an operation. To "do a perineum" in five or seven minutes still serves as an attraction for the lookers-on in many private hospitals and gynecologic clinics. I fully appreciate the value of a well-performed perineorrhaphy in proper cases, but I am equally well satisfied that the operation has often been performed unnecessarily, and that it requires more than five or seven minutes to perform it properly. The late lamented Robert Battey opened a wide field for operative gynecology. This modest, honest worker conceived the idea that the removal of

the normal ovaries would become a useful surgical resource in the treatment of certain nervous affections which before had baffled the skill of physicians. It required some time and the additional support of Hegar and Tait for his views to become popular among his colleagues. Battey lived long enough to learn that his example and teachings have created a wave in the misapplication of the art of surgery which to-day remains mountain high, and it is difficult to tell where it will end or where a rock sufficiently high and strong will be found to break its force. The frequency with which women are being castrated to-day is one of the most flagrant transgressions of the limits of the art of surgery. It is not unusual for one operator to exhibit from five to six normal ovaries as the result of half a day's work. All kinds of excuses are made for this kind of surgery. The ovaries are too large, cirrhotic, cystic, or perchance a ruptured Graafian follicle is discovered, when he consoles himself that he has removed an apoplectic ovary. Where is this wholesale unsexing of our female population going to end? The beginning of the end has come. The army of women minus their essential organs of generation is beginning to raise its voice against such mutilating work. The number of women who willingly sacrificed their ovaries to restore their shattered health without securing the expected relief has increased to an alarming extent. This sad experience has made the gynecologists more desperate and bold. They have been importuned by their castrated, tubeless patients to such an extent that the art of surgery was again resorted to. The uterus, which heretofore had been comparatively safe, was now selected as the offending body, and vaginal hysterectomy became at once a popular operation. Many atrophic uteri remaining after removal of their appendages have been removed in a vain hope of securing permanent relief. Vaginal hysterectomy for diseases other than carcinoma is now at its height. The uterus is being removed for hypertrophy, endometritis, flexion, version and minute myofibromata. This important organ is no longer safe if it is in the vicinity of a pelvic abscess. Perchance a healthy uterus is removed under the pretense of securing a more direct route to a focus or foci of pelvic inflammation. It is needless to say that most of the surgeons who clamor for the removal of the uterus through the vagina for insignificant affections or inflammatory lesions of adjacent parts, do so by the use of compression forceps. It is no great surgical feat to squeeze out an inflamed or displaced uterus between compression forceps. It is difficult to say where this rage for the removal of the female sexual organs will end or what organ will be the next battle ground for the aggressive gynecologists. The clitoris, the vagina, the cervix uteri, the ovaries, the Fallopian tubes, the uterus and its ligaments have successively passed through a trying ordeal of the *furor operativus*. What the next fad will be is impossible to foretell. As one operation after another is falling into a well deserved desuetude new ones will have to be devised to gratify the whims of the patients and the ambitions of the gynecologist. I have portrayed to you only a few of the excesses of the art of surgery as applied to the female organs of generation, but enough has been said to show you that it is time to call a halt. Further depredations can best be avoided by the general practitioners to whom most of the patients first apply for relief. Let them do their duty toward their patients. Many of the minor affec-

tions of the uterus and its appendages are within the reach of intelligent general and local treatment without a recourse to the knife. If gynecology is to live and become a real benefit to women suffering from pelvic disease, it must become more conservative. We all appreciate what surgery has done in prolonging life and in mitigating suffering in the treatment of ovarian cysts and the removal of the uterus, the seat of symptom-producing myofibromata. What I am objecting to, and on good ground, is the indiscriminate operating upon the female organs of generation for imaginary or insignificant affections. This is an evil that must be apparent to all and that the leaders of gynecology must assist us to suppress.

I can not dismiss the subject of genital surgery without making a strong plea in favor of conservatism in the treatment of prostatic hypertrophy. A few years ago J. W. White made a series of experiments on dogs which proved that the testicles possessed an influence which, to a certain degree, controlled the nutrition of the prostate gland. His experiments were made on dogs, the animals being vigorous and in full possession of their sexual power. He found that castration was constantly followed by progressive atrophy of the prostate gland. At that time he timidly suggested that castration in cases of prostatic hypertrophy might possibly prove to be a valuable surgical resource in the treatment of urinary obstructions due to such a cause. About the same time Ramm gave the result of his clinical experience, covering about the same ground, urging the utility of castration as a legitimate surgical procedure in the treatment of non-malignant obstructive enlargement of the prostate, a condition so frequently met with in men advanced in years. You are familiar with the subsequent history of this operation. Numerous operations have been performed in different countries which appear to support the claims made for it by both of these investigators. The operation has been modified in substituting for the castration section or resection of the vas deferens, and recently neurectomy of the spermatic nerves; both of these procedures are said to produce the same curative effect as castration. A sufficient clinical material has accumulated to prove that these different procedures frequently result in diminution in the size of the prostate and that the symptoms caused by the obstruction often diminish or disappear.

I can readily understand in what manner emasculation in young animals and young and middle-aged men should be followed by atrophy of the healthy prostate gland. Castration of women during active sexual life will bring about atrophy of the uterus as a constant result. Clinical experience has also shown that the anticipated menopause effected by castration has a decided effect on the myomatous uterus. But who would think of castrating a woman who has reached the menopause for such an indication? It is very difficult to understand how castration or its substitutes performed on men advanced in years, with atrophic dormant testicles should exert such a positive influence upon an organ, the seat of a senile affection. And yet, the fact remains that many reliable men have observed such results, and we can no longer doubt them.

What I fear, and the reason I allude to this subject, is this, that castration of aged men for hypertrophy of the prostate, when this operation becomes common property and is endorsed by surgeons who stand high in the estimation of the profession, will be misap-

plied in the same way, fortunately, probably to a lesser extent than the removal of normal ovaries. Men will be castrated for stone in the bladder, chronic cystitis and malignant disease of the bladder. It is not always easy nor possible to make a positive differential diagnosis between simple hypertrophy of the prostate and some of the conditions which simulate it so closely. In doubtful cases it appears to me it would certainly be advisable to make the diagnosis sure by a supra-pubic cystotomy before resorting to a mutilating operation, rather than remove the testicles and later discover a tubercular bladder or encysted stone or malignant disease of the bladder or prostate. Castration is such an easy operation that every tyro in surgery will be tempted to perform it upon willing subjects suffering from obscure affections of the bladder, complicating hypertrophy of the prostate gland. The Ramm-White operation deserves a fair trial at the hands of competent surgeons, in well selected cases, but I apprehend evil in the future, not so much from the proper use as the abuse of this procedure. In short, it is probable that this new surgical resource, which has not yet passed the trial stage of a legitimate established surgical procedure, will on a smaller scale become a repetition of the unenviable history of castration of the opposite sex. We have every reason to believe that so far the apparently successful cases have found their way into current medical literature, while the cases in which the operation has proved a failure, with few exceptions, have for apparent reasons not been published.

Gentlemen: It has been my purpose to call your attention in the brief time allotted to the delivery of this address to some of the limits of the art of surgery and to a few of the most flagrant prevalent trespasses of its legitimate limits by indiscriminating surgeons. I wish time would permit me to say something of the too frequent recourse to the recently revived operation of symphyseotomy and the unwarranted procedure known as Porro's operation, except in cases in which the uterus is the seat of a life-threatening affection, some of the evil results following the too frequent performance of ventro-fixation of the retroverted uterus, and many other topics in general surgery and gynecology to which no allusion has been made, where the limits of the art of surgery have been ignored, and too often reckless operating has disgraced the fair fame and reputation of our noble profession. Let us have in the future more of the *nil nocere* in place of the *furor operativus*. I have written and delivered this address with malice toward none, in the interest of the suffering portion of our population, for the true advancement of the science and art of surgery, and as a plea for recognition of the good work done by the great mass and backbone of our profession, the modest, toiling, inadequately remunerated general practitioner.

Benefactions to Boston Charities.—By the death of an heir the public bequests under the will of Mrs. Josiah Vose, of Boston, Mass., became operative and more than \$380,000 is released to many of the more prominent educational and charitable institutions in Boston. These bequests are: Massachusetts General Hospital, \$30,000; McLean Asylum, \$30,000; Institute of Technology, \$25,000; Female Orphan Asylum, \$15,000; New England Hospital for Women and Children, \$25,000; Institution for the Blind, \$10,000; Eye and Ear Infirmary, \$15,000, and Home for Colored Women, \$5,000.

ADDRESS ON THE CHARACTER OF DR. EDWARD JENNER AND THE HISTORY OF HIS DISCOVERY OF THE PROTECTIVE VALUE OF VACCINATION.

Read at the Centennial Anniversary, Atlanta, Ga., May, 1896.

BY N. S. DAVIS, M.D., LL.D.

CHAIRMAN COMMITTEE, CHICAGO, ILL.

According to reliable authorities the subject of this address, Edward Jenner, was a native of Berkeley, in Gloucestershire, England. He was born May 17, 1749. His father was Rev. Stephen Jenner, who was rector of Rockhampton and vicar of Berkeley. He was the representative of an honorable family long established and owning some landed property in that county. His mother belonged to an ancient family in Berkshire. The father died when Jenner was only 6 years old, thereby leaving the care and education of Edward almost wholly to his older brother, Rev. Stephen Jenner, who appears to have assumed and executed all the parental duties relating to the younger brother with the utmost fidelity and tenderness. The early education of Edward was in the schools, chiefly at Wotton-under-Edge and Cirencester. During this time he developed so much fondness for natural history as to attract special attention, yet he was never behind in any other studies required. At the age of 14 it was decided that his further education should have direct reference to his entering the medical profession. Consequently he was apprenticed to Mr. Daniel Ludlow, a surgeon at Sudbury, near Bristol, for the purpose of studying surgery and pharmacy. It was during this apprenticeship that he heard a young woman, a milkmaid of the neighborhood, say to Surgeon Ludlow that she could not have the smallpox because she had previously had a cowpox sore on her hand contracted while milking. The remark was such as to indicate a prevalent belief among some of those engaged in milking, that there sometimes existed on the udders of the cow a sore or pustule the matter from which, if placed in contact with an abrasion on the hand of the milker, produced a peculiar sore, leaving a permanent scar and rendering him or her ever after immune to the contagion of smallpox. No attention was given to the remark by the surgeon, who like all his confrères regarded it either a mere accidental occurrence, or a superstitious vagary of the common people. But it was far otherwise with his young apprentice, Edward Jenner.

Endowed with the highest order of mental acumen, coupled with an equally high order of benevolence, and already trained to philosophical study, the simple remark of the milkmaid at once and indelibly fixed in his mind the question whether it did not point to a possible preventive of that most dreaded scourge of the human race, smallpox. Jenner never abandoned the idea of solving the question until he had completed its solution thirty years later. But with no accurate description of the alleged infectious sore or pustule on the cow's udder, and the fact that it was met with only at irregular intervals, he was limited during his apprenticeship to the gathering of such items of information bearing on the subject as might come within his reach. In the meantime he not only pursued his studies in surgery and pharmacy with diligence, but he seems to have devoted every available hour to further studies in natural history directly in the open field of nature, observing the habits of liv-

ing animals, gathering fossils, and acquiring unusual skill in drawing. At the expiration of his seven years of apprenticeship with Surgeon Ludlow, in 1770, at the age of 21 years he went to London for the further prosecution of his medical studies. He entered as a student at St. George's Hospital and became a private pupil of the celebrated John Hunter, in whose family he resided during the next two years. During this pupilage he early displayed so much skill and accuracy in making preparations of anatomy and natural history, and in dissecting delicate structures, both natural and pathologic, that he rendered much aid to his preceptor. So marked were these attainments that through the recommendation of Mr. Hunter he was employed by Sir Joseph Banks to arrange the valuable specimens, zoölogical and otherwise, gathered by Captain Cook during his first voyage of discovery ending in 1771. He performed the work so satisfactorily that he was offered the position of naturalist to the next expedition the following year. But his attachment to his older brother and to his native town caused him to decline this offer, and at the end of two years' study in London he obtained the necessary license to practice surgery and returned to practice in his native town of Berkeley at the beginning of 1773. While with Mr. Hunter, young Jenner mentioned his question of the possibility of making the cowpox a valuable preventive of the natural smallpox and subsequently corresponded with him on the subject. He was encouraged to make a thorough investigation, which he entered upon earnestly in 1775, or as soon as he had become established in the practice of his profession.

The first five years were consumed in fairly identifying the true cowpox vaccine pustule and separating it from other sores with which it had been confounded. During the same time his investigations led him to believe the true cowpox pustule yielded its active virus only at a certain stage of its advancement, and that it, together with the diseases known as swinepox and the grease in horses, were all derived from the action of smallpox contagion on these animals. So firm was his belief in the truth of this, that during a period of unusual absence of cowpox from the neighborhood, he ventured to vaccinate his oldest son with the matter of swinepox and produced in him all the symptoms of a very mild case of smallpox. After his recovery he was inoculated with genuine smallpox without effect. This gave him so much confidence in the ultimate success of his investigations that in 1780 he communicated confidentially to his intimate friend, Edward Gardner, the progress he had made and his confident belief that its results would be of the greatest benefit to the human race. In 1788 he carried an accurate drawing of the cowpox sore, as seen on the hand of a milkmaid, to Sir E. Home and others in London, who seemed to regard it as a curious and interesting illustration, but gave no evidence of perceiving its practical importance.

Finally, on the 14th of May, 1796, the long sought opportunity came, and he was enabled to take the lymph from a cowpox pustule on the hand of Sarah Nelmes and with it vaccinate the arm of James Phipps, a boy in good health, and aged 8 years. The vaccine disease passed through its successive stages perfectly and Jenner was surprised at the general resemblance of the vaccine sores to those of smallpox. About twenty days after the boy Phipps had recovered from his vaccination, his arms were inocu-

lated with smallpox matter without effect. The circle of proof was now complete. The vaccine lymph from the cowpox sore produced the characteristic vaccine on the hand of the milkmaid. The lymph from the vaccine sore on her hand produced the characteristic vaccine sore on the healthy boy, and both proved ever after entirely immune to the contagion of smallpox. Still Dr. Jenner patiently continued two years more in extending and verifying his proofs that there might be no reasonable chance of failure in the complete establishment of his great discovery. He then, early in 1798, wrote in a paper frankly all the important steps of his investigations and the full proofs of his discovery and its inestimable value to the human race, intending to submit it as a communication to the Royal Society, to which he had previously made acceptable communications on other subjects. But we are told by Dr. John Baron, the chosen biographer of Dr. Jenner, that the president of that Society, Sir J. Banks, advised him to be very cautious, lest such a paper should lessen the reputation he had already gained. Accordingly Dr. Jenner, with a supply of vaccine lymph, went to London for the purpose of directly demonstrating its effects to prominent members of the profession in that city. After tarrying there two or three months without finding a single individual who would submit to the simple process of vaccination, near the end of June, 1798, his paper was given to the world in an unpretentious pamphlet, dedicated to his friend, Dr. Parry of Bath, and he returned to his home in Berkeley. He however left with Mr. Cline, of St. Thomas' Hospital, a supply of the vaccine lymph, and this eminent surgeon soon found an opportunity to insert some of the same into the hip of a boy complaining of hip-disease. It was done under the plea of creating necessary counter-irritation, and perfect vaccine sores resulted therefrom. After fully recovering from the vaccination the boy was inoculated in three places with active smallpox matter without producing any of the symptoms of that dreaded disease. With this marked demonstration Mr. Cline became an active advocate of Jenner's discovery, and there was no longer difficulty in finding either physicians or patients willing to practically test its value.

Indeed, in less than twelve months after the publication of Dr. Jenner's pamphlet, a manifesto fully endorsing the truthfulness and value of his discovery was published, signed by seventy-three of the most eminent members of the medical profession in London. Within the same period of time the practice of cowpox vaccination was introduced into this country by Dr. Benj. Waterhouse, Professor of Physic at Cambridge, Mass., who vaccinated members of his own family; and the practice spread rapidly throughout the United States. Under the judicious leadership of Dr. de Carro, of Vienna, the practice of vaccination was rapidly introduced into all the countries of central and southern Europe.

In Spain it was warmly welcomed by both physicians and clergy, by whom a knowledge of it was rapidly communicated to all her colonies on this side of the Atlantic. In Russia the cause of Dr. Jenner found an efficient advocate in the Empress, who introduced the practice of vaccination in her own family, and facilitated its extension to Siberia and the countries of Asia.

Within the short period of two years after the original pamphlet of Dr. Jenner, entitled: "Inquiry

into the Cause and Effects of the Variolæ Vaccinæ." London, 1798, it had been translated into nearly every language in Europe. And within six years the practice of vaccination for the prevention of smallpox had been introduced and sanctioned in every civilized and even semi-civilized country on the globe.

Such is a simple narrative of the inception, patient prosecution, and final completion of the great discovery of the true cowpox lymph and its efficacy as a preventive of smallpox by Dr. Edward Jenner. And thus was the result of more than twenty years of thoughtful, skillful, persevering investigations given to the world with the utmost freedom and truthfulness. It was accompanied by no fictitious names, no unexplained processes, and no hint at selfish or pecuniary recompense. On the contrary, he was among the most zealous in extending its benefits to all classes, and especially to the poor. And he apparently looked only for the fulfillment of Lord Bacon's saying: "That it is heaven upon earth, to have a man's mind move in charity, rest in providence, and turn upon the poles of truth." While it is true that Dr. Jenner's discovery was received and adopted both by the medical profession and the masses of the people of all civilized countries with the extraordinary rapidity just described, it was not without the bitter opposition of some persons, and the injurious effects of a few over zealous or injudicious friends.

To correct the errors and misstatements of these and to furnish additional facts of value, Dr. Jenner published a paper entitled: "Further Observations on Variolæ Vaccinæ, London, 1799;" another on "A Continuation of Facts and Observations Relative to the Variolæ Vaccinæ, London, 1800;" and the same year, "A Complete Statement of Facts and Observations Relative to the Cow-Pock;" followed by another "On the Origin of Vaccine Inoculation, London, 1801." But in no one of these additional publications did he exhibit the ordinary spirit of controversy.

All were characterized by the highest degree of candor and regard for truthfulness, and he continued the practice of his profession in his native town regardless of the most flattering inducements to change his residence to London. In 1788 he had married Miss Catherine Kingscote, a lady admirably qualified to add to his social and domestic happiness. In 1792, wishing to lessen the pressure of his professional practice by changing its direction, he obtained from the University of St. Andrews the degree of Doctor of Physic. However, he not only continued a lucrative practice and actively maintained a social organization of his neighboring practitioners, but he also continued to give so much attention to studies in natural history that he was in 1788, or soon thereafter, elected a member of the Royal Philosophical Society of London. Notwithstanding all these proofs of his love of home, of domestic happiness, of nature in her native garb, and above all, of nature's God, during the few years immediately following the publication of his discovery, he was overwhelmed with correspondence from every quarter, to such an extent that, in his own expressive language, he was forced to become "Vaccine Clerk for the World." In addition to this, congratulatory communications came to him from kings, queens, officers of state and of learned societies, until he soon found himself elected to membership in nearly all the scientific societies in Europe. If we add to all these time-consuming topics, the fact that he continued to devote a certain amount of time

each day to the gratuitous vaccination of the poor at his own home, we shall see that his time for pursuing the paying part of his professional practice was seriously impaired. This did not escape the observation of his neighbors and most intimate friends, who near the close of 1801 presented him as a testimonial, a service of plate, which was designed, in reality, as a prelude to the obtaining of his consent to a petition to Parliament for a suitable grant of money. Such a petition was presented on the 17th of March, 1802, and was referred to a committee of which Admiral Berkeley was chairman. After proper investigation, the committee reported favorably and Parliament voted a grant of \$50,000. Four years later, 1806, after the Royal College of Physicians had reported favorably on the continued success of vaccination, Parliament voted an additional grant of \$100,000. Five or six years later still, subscriptions were taken up in the East, and those forwarded from the three Presidencies of Bengal, Bombay and Madras, aggregated little more than \$35,000.

In 1808 Dr. Jenner was elected a Corresponding Member of the National Institute. Subsequently he was elected Mayor of Berkeley, and in 1813 he was granted the degree of Doctor in Physic by the University of Oxford, by special decree of the Convocation. His otherwise most happy domestic life received its first shade of sadness from the death of his oldest son in 1810, leaving him still one son and one daughter. But the deeper sorrow came Sept. 13, 1815, when Mrs. Jenner, after a protracted sickness, died. From this time Dr. Jenner lived in practical retirement, having made his last visit to London the year previous, when he was presented to the allied sovereigns and many other distinguished persons then assembled in that city. Though in practical retirement during the last eight years of his life, he not only found serene enjoyment in the fields and groves of his native town, but sufficient occupation also in still gathering facts concerning the results of vaccination particularly as connected with other cutaneous eruptions, and in discharging the duties of physician, naturalist and magistrate.

He published his last paper in 1822, "On the Influence of Artificial Eruptions in Certain Diseases." His last written expression concerning the general subject of vaccination was found on the back of a letter dated Jan. 14, 1823, and is copied by his biographer, Dr. Baron, as follows: "My opinion of vaccination is precisely as it was when I first promulgated the discovery. It is not in the least strengthened by any event that has happened, for it could gain no strength; and it is not in the least weakened, for if the failures you speak of had not happened the truth of my assertions respecting those coincidences which occasioned them, would not have been made out."

Dr. Jenner is reported to have had a mild attack of apoplexy Aug. 6, 1820, from which he quickly recovered. Another and severe attack came suddenly on the morning of Jan. 25, 1823, from which he died the following morning in the 74th year of his age. His body was buried in the chancel of the parish church of Berkeley, Feb. 3, 1823, in the presence of a large concourse of people.

A good picture of him by Sir Thomas Lawrence is given in connection with a biography in Vol. II of the Medical Portrait Gallery by Thomas Joseph Pettigrew, F. R. S., etc. Soon after his death an excellent statue of him by Sievier was placed in the cathe-

dral at Gloucester,¹ and 1858 a more expensive one was erected in London.

In 1808 Dr. Jenner met and formed an acquaintance with Dr. John Baron, then just entering upon the practice of his profession. This acquaintance soon ripened into a most intimate mutual friendship, which continued to the end of their lives. The trustees of Dr. Jenner's estate placed all his papers, manuscripts and correspondence in the hands of Dr. Baron as the most suitable person for furnishing a full and correct biography of the former. He accepted the task with reluctance on account of the pressure of other engagements, but nevertheless completed it in two volumes, published in 1827, with so much painstaking detail, accuracy and candor as to receive from all the highest degree of commendation. Dr. Baron appears to have appreciated not only the permanent value of every fact connected with the great discovery of Dr. Jenner, but he appreciated also his motives, his attainments and his boundless benevolence, and hence his biography was made so complete, that it has furnished nearly all the facts and materials used by subsequent writers when referring to the subject.

During the last fifty years it has been a very common custom for newspaper, magazine and even medical writers to represent the members of the regular medical profession as so conservative, or wedded to preconceived opinions, that every new discovery was received with reluctance and its author generally persecuted into poverty. But I have searched the pages of medical history from the time medicine began to develop a scientific basis in chemistry and anatomy, in the fifteenth century to the present time, without finding any proof of the correctness of this very popular allegation. On the contrary, every important discovery in chemistry, anatomy, physiology, etiology, pathology or therapeutics that was susceptible of proof by any reliable methods of investigation has been accepted and incorporated into our medical literature in less than ten years after its promulgation, and with due credit to its author.

The spirit of conservatism has at no time been more than sufficient to insure a fair examination of the various bearings of any given proposition; and in recent times often not even sufficient for that. One of the most remarkable items connected with the history of the discovery of cowpox vaccination, was the twenty years of the patient, persevering investigation by Dr. Edward Jenner before he deemed his proofs sufficient to justify him in announcing it to the world. And the next most noted event was the rapidity with which it was accepted and practically applied by the medical profession in all parts of the world. As has been previously stated, the announcement of Dr. Jenner's discovery called forth from a few physicians and others strenuous opposition; and the same class of peculiarly constituted individuals have been perpetuated until the present time. They are found filling the ranks of the mind-curists, Christian scientists, anti-vaccinationists, anti-vivisectionists and anti-common-senseists of the present day. But they embrace in their ranks very few regularly educated members of the medical profession. In speaking of medical discoveries it may not be amiss to say, we mean the announcement of such new facts or truths as are capable of demonstration by legitimate or scientific methods, as distinguished from the announcement of mere metaphysical theories or exclusive

dogmas, of which the eighteenth century was peculiarly prolific. The first have always been accepted and incorporated into the proper department of our permanent medical literature, while the latter have with equal uniformity gained popularity for a time, generally in proportion to the mystery in which they were enveloped, and then given place to their successors. This is well illustrated by comparing the present position of the real discovery of Dr. Jenner with the two most pretentious theories of the same century. For it must be remembered that this is not only the centennial anniversary of the discovery of Jennerian vaccination, but it is equally the centennial anniversary of the announcement of the so-called new or phrenological system of mental philosophy by Dr. Gall in his lectures in Vienna, Austria, 1796, and also of the appearance of an "Essay on a New Principle for Ascertaining the Curative Properties of Drugs," by Dr. Christian Friedrich Hahnemann, of Germany, which was the real initiation of the two so-called, universal and immutable laws that "like cures like," and "the greater the attenuation or dilution of the drug the greater its curative power." The new mental philosophy of Dr. Gall, though advocated with the eminent ability of Drs. Spurzheim and Andrew Combe, as destined to revolutionize our ideas of mental philosophy as well as the ordinary principles of education, was so plainly founded on hypothetic or imaginary lines as to admit of no proof either anatomic, physiologic or pathologic and consequently it gained only a partial recognition by medical men, and its advocates were soon induced to make their appeals to the non-professional public. And now at the end of the century its peripatetic lecturers and phrenologic fortune-tellers, can hardly attract anywhere a popular audience sufficient for an evening's amusement. So, too, the purely speculative theories of Hahnemann, being capable of proof by no scientific processes or natural laws, gained so few advocates among the members of the profession, that after the first ten years their author abandoned the ordinary channels of medical literature and appealed directly to the non-professional public and proclaimed them as constituting a new and universal system of medicine. The result is, that the system of Hahnemann now on its first centennial anniversary, has neither legal nor general medical recognition in Europe; and in this country of free fadisms, the number who actually adhere to the practical application of its so-called fundamental laws is not equal to the number of those who may still be found in the ranks of the anti-vaccinationists. And yet its nominal advocates still call it the "new school" of medicine, though born full-fledged an hundred years since; and they attribute its non-acceptance by the general medical profession solely to the stolid conservatism of said profession. Such is the origin of the popular fallacy concerning the reluctance of the medical profession to embrace new discoveries, while, in truth, there is no other class of educated people to be found, whose history proves it more ready to receive and appropriate new facts or real discoveries and to reject mere theoretic dogmas. But my task would be inexcusably defective did I not add to the simple history of the truly great discovery of the protective power of cowpox vaccine virus, some comments on the personal character of the discoverer himself. For, if we may credit the combined testimony of his chosen and most competent biographer, Dr. John Baron, and his contemporaries,

¹ See London *Lancet* for 1881, for an account of statue to Jenner.

the character of Dr. Edward Jenner is one of the most interesting and remarkable to be found on the records of medical history. Born in a quiet country town, of parentage of intelligent and high moral or religious qualities, and spending his childhood and youth under the same influences in the midst of his native groves and meadows it was natural that he should develop a passionate love of nature and a marked reverence for nature's great Architect. And receiving his general education, not in the higher colleges or universities, but in the more quiet though excellent local schools near his parental home, still further tended to foster that fondness for the study of natural history and, indeed, all the natural sciences in which he became proficient in after life. No other environment or influences could have been better calculated to develop into unusual prominence the three most remarkable traits in the character of Dr. Jenner, namely, his love of nature and all that is truthful and good, his benevolence or unselfish desire to prevent or relieve human suffering, and his patient and persevering pursuit of whatever promised to result in material benefit to mankind. The last-named element of his character has been amply illustrated by what has already been said of his more than twenty years of earnest pursuit of a reliable preventive of smallpox, regardless of the indifference of his professional brethren generally, and of the positive jeers of some of those most nearly in association with him. His love of nature and genuine reverence for the author of all good is admirably illustrated in a letter to a friend written when the evidences of the genuineness of his discovery were nearing completion. He says: "While the vaccine discovery was progressive, the joy I felt at the prospect before me of being the instrument destined to take away from the world one of its greatest calamities, blended with the fond hope of enjoying independence and domestic peace and happiness, was often so excessive, that in pursuing my favorite subject among the meadows, I have sometimes found myself in a kind of reverie. It is pleasant to me to recollect that these reflections always ended in devout acknowledgements to that Being from whom this and all other mercies flow."

But the most vivid illustration of Dr. Edward Jenner's unselfish nature and of his noble conceptions of the true objects of human life is found in his answer to the most tempting inducements to leave his native town and enter upon a professional contest for wealth and fame in the great city of London. We are assured by his biographers that after the full demonstration of the truth of Dr. Jenner's discovery by Mr. Cline, the latter urged him to settle in London, promising him £10,000 (\$50,000) per annum as the result of his practice.

To this, however, his deliberate reply was: "Shall I, who even in the morning of my days sought the lowly and sequestered paths of life, the valley and not the mountain; shall I, now my evening is fast approaching, hold myself up as an object for fortune and fame? Admitting it as a certainty that I obtain both, what stock should I add to my little fund of happiness? My fortune, with what flows in from my profession, is sufficient to gratify my wishes; indeed so limited is my ambition, and that of my nearest connections, that were I precluded from future practice I should be enabled to obtain all I want. And as for fame, what is it? A gilded butt, forever pierced with the arrows of malignancy."²

Did the combined temptations of offered wealth and fame ever receive a more fitting reply? And has there ever been penned a more stinging rebuke to the manifest commercial, money-making, fame-seeking spirit pervading the ranks of the profession of the present day. To have an intelligent appreciation of the beauties, the harmonies and the beneficence of nature, with genuine reverence for nature's great Architect; to labor diligently for the prevention and relief of human suffering, and the elevation of the race; and at the same time to be content with a competence sufficient to supply all our real wants, is not only a true exemplification of the letter and spirit of our national code of medical ethics, but it is equally an exemplification of the only sure road to human happiness here or hereafter. Such was preëminently the life and character of Dr. Edward Jenner, one of the noblest benefactors of the human race.

For an account of the present status of vaccination in our country, and the chief obstacles in the way of realizing all the benefits its faithful and universal application would confer, I refer you to the members of the various parts of this widely extended country who are expected to take part in the discussion which is to follow.

However, as the shades of sixty years of professional toil and 80 years of life are already upon me, and I may never again have an opportunity to address you even by proxy, I must be allowed to remind you that I deem this to be the true semi-centennial of this great national Association; and to congratulate you on the substantial accomplishment of the leading object which prompted its formation, namely, the placing of our system of medical education on a broader, more systematic and more efficient basis. I am filled with contentment and thankfulness that I have been permitted to live until this day. And I sincerely thank you for so patiently listening to this address.

SCIENTIFIC RESEARCHES RELATING TO THE SPECIFIC INFECTIOUS AGENT OF SMALLPOX AND THE PRODUCTION OF ARTIFICIAL IMMUNITY FROM THIS DISEASE.

Read at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY GEORGE M. STERNBERG, M.D.

SURGEON GENERAL U. S. ARMY,
WASHINGTON, D.C.

Gentlemen:—A complete review of the experimental researches which have been made with a view to demonstrating the exact nature and biologic characters of the specific infectious agent which by its multiplication in the body of a susceptible individual gives rise to the disease known to us as variola, or smallpox, would require a volume. But at the end of this volume I would be obliged to record as the principal conclusion reached, the fact that the specific infectious agent in this disease has not been demonstrated. It does not follow from this statement that the researches made have been without value. If this were so I might dismiss this portion of my subject without further remark. But the present occasion calls for something more than this: for, while we

² See Vol. II., Medical Portrait Gallery, Port. Edward Jenner.

are here chiefly to celebrate the centennial of Jenner's great discovery and to consider the beneficent results which have followed its extended application in the civilized countries of the world, we must also give attention to the unsolved problems connected with vaccination, and by a brief review of the literature relating to these problems endeavor to ascertain in which direction our efforts should be turned in future, with a view to their solution.

The principal problem which confronts us is the one already stated. What is the nature of the specific infectious agent? That it is a living microorganism of some kind can scarcely be doubted when we consider the general arguments in favor of a *contagium vivum* in infectious diseases, in connection with our exact knowledge of the etiology of a considerable number of these diseases. But it is proper, in this connection, to call attention to the fact that in the group of infectious diseases to which smallpox belongs—the eruptive fevers—no demonstration has yet been made as to the precise nature of the microorganism which we believe to be present in the infectious material by which these diseases are propagated. The demonstration that certain infectious diseases of man and of the lower animals are due to the presence of bacteria, having specific morphologic and biologic characters by which they can be differentiated one from another, led for a time to the inference that all infectious diseases must be due to the presence of microorganisms of the same class. But the negative results which have attended the extended researches already made give support to the view that the eruptive fevers must be due to microorganisms of a different class, inasmuch as our staining and culture methods fail to demonstrate the presence of specific bacteria in the blood or tissues. Bacteria have, however, been found in the blood and tissues, in a certain proportion of the fatal cases, in the diseases of this group; and these were supposed by some of the earlier investigators to bear an etiologic relation to the diseases in question. But the more precise methods of investigation introduced by Koch have made it evident that these bacteria are not directly concerned in the specific disease processes, and that they are to be regarded as accidentally present, or as representing a secondary infection. The bacteria found under these circumstances are for the most part micrococci, and especially the well known pus cocci—*staphylococcus pyogenes albus*, *staphylococcus pyogenes aureus*, and *streptococcus pyogenes*. The frequency with which these cocci are found in the eruption of variola and of vaccinia, both in the vesicular and in the pustular stages of development led to the description, by Cohn, of his *micrococcus vaccinae*. The description, as given in my translation of Magnin, published in 1880, is as follows:

"*M. vaccinae*, Cohn (*Microsphaera vaccinae*, Cohn.) Very small micrococci, $=0.5 \mu$ scarcely, isolated or united in pairs in recent vaccine virus and in the pus of variola pustules. By cultivation, chaplets of from two to eight cells may be obtained, then masses containing sixteen to thirty-two cells of 10μ and more in diameter." According to Cohn the micrococci of vaccine virus and of variola were to be regarded as different races of the same species. Evidently his conclusions were based upon insufficient data and preconceived notions. But it must be remembered that at the time they were formulated Koch had not yet resorted to the use of solid culture media and the

plate method for the differentiation of bacteria; and the essential requirements of a scientific demonstration of the etiologic relation of a microorganism to a specific infectious disease had not been stated by him, or generally recognized by those engaged in bacteriologic researches. Subsequent investigations have shown that various micrococci and bacilli are found in the pustules of smallpox and in vaccine lymph, and that no one of these, when isolated in a pure culture, will cause the development of a typical vaccine vesicle. Researches relating to the bacteria present in vaccine lymph were greatly stimulated by the offer, by the Grocer's Company of London, of a prize of £1,000 for the discovery "of a method by which the vaccine contagium may be cultivated apart from the animal body in some medium or media not otherwise zymotic—the method to be such that the contagium may by means of it be multiplied to an indefinite extent in successive generations, and that the product after any number of such generations shall (so far as can within the time be tested) prove itself of identical potency with standard vaccine lymph." This offer was made in May, 1883, but up to the present time, so far as I am informed, the prize has not been awarded.

Among those who were induced to make researches in competition for the Grocer's Company prize we may mention Dr. John Dougall, Health Officer of Glasgow. His "Competitive Essay" is published in the Glasgow Medical Journal of December, 1886, and January, 1887. He obtained cultures of micrococci from vaccine lymph, in the various media employed in his investigations, and made numerous vaccinations with these cultures. Some of these appeared to be attended with partial success, but his critical review of his own experiments shows that this apparent partial success was due to the fact that "natural and artificial lymphs (cultures) were nearly always used simultaneously, on the same arm, and in close proximity, and it was found that when artificial lymph proved successful (?) the vesicle was nearly always small and imperfect." In his "conclusion" Dr. Dougall says: "The results of this inquiry, based on the foregoing experiments, do not fulfill the terms of success in solving the announced problem. In other words, I have failed to cultivate vaccine lymph in artificial soils." Dr. Dougall, not being an experienced bacteriologist, apparently assumed that the micrococci obtained by him from vaccine lymph were all of one species; at least he gives no account of an attempt to differentiate species by the plate method. This differentiation has been made, however, by other bacteriologists. Thus Copeman (1891) says:

"As it was evident that more than one organism could usually be obtained by the inoculation of lymph into nutrient media, plate cultivations were made with the object of separating out the different varieties present, both gelatin and glycerin-agar being used for this purpose. In this manner I succeeded in obtaining pure growths of various microorganisms, of which those which almost invariably occurred included micrococci apparently much resembling, if not identical with, the following: 1, *M. pyogenes aureus*; 2, *M. cereus flavus*; 3, *M. epidermis* (? *Staphylococcus albus*, Klein).

"In these observations I find my experiments are in agreement with those of Pfeiffer, while doubtless these various micrococci correspond respectively with Buist's so-called orange, yellow, and white vaccine. In addition, I occasionally found another organism,

which from its morphologic and microscopic characteristics, I believe to be streptococcus pyogenes. In order to test what action, if any, these various microphytes were capable of exerting, they were inoculated, both in pure culture and mixed in various proportions, not only on the calf, but on the human being and on the rabbit, since this latter animal is apparently susceptible to vaccination performed in the ordinary manner. Such inoculations, for the most part, produced little or no effect, although inoculations of streptococcus pyogenes alone occasionally caused the appearance of a small circumscribed inflammatory patch around the point at which it was inserted. In one instance, also, a rabbit died, apparently of septicemia, after inoculation of a mixed growth of the various organisms previously mentioned together with a certain amount of broth in which they had been grown. In the whole series of inoculations, nothing resembling a vaccine vesicle was seen, so that it was, apparently, pretty certain that none of the organisms that had been isolated in the manner described could be directly concerned in the causation of vaccinia."

Pfeiffer, in addition to staphylococcus pyogenes albus, which was most constantly present, obtained the following species: Staphylococcus pyogenes aureus, occasionally; staphylococcus cereus albus, very frequently; four species of sarcinae (*S. lutea*, *S. tetragonus*, *S. aurantiaca* and *S. muscopus*), occasionally; proteus vulgaris and certain non-liquefying bacteria, occasionally. He also found occasionally in human lymph, and always in calf lymph, a species of saccharomyces.

Crookshank (1891) obtained from calf lymph the following bacteria: Specimen No. 1 yielded a torula, bacillus pyocyaneus and bacillus subtilis; No. 2, a bacterium, a variety of proteus, staphylococcus pyogenes aureus, yellow bacterium; No. 3, a bacterium, micrococcus, yellow bacterium and torula; No. 4, yellow micrococcus, white micrococcus, white torula, yellow sarcina, white diplococcus, staphylococcus cereus albus, and a mold fungus; No. 5, yellow sarcina, staphylococcus pyogenes aureus, yellow micrococcus, white bacillus, staphylococcus pyogenes albus, large white micrococcus, yellow bacterium, and a white micrococcus. Among the specimens of human vaccine lymph, No. 1, contained a white micrococcus, proteus and staphylococcus pyogenes aureus; No. 2, a micrococcus, a tetracoccus, a white liquefying micrococcus, and a yellow bacterium; No. 3, white micrococcus, yellow micrococcus, staphylococcus aureus and flavus, a bacterium, a white micrococcus, a bacillus resembling bacillus subtilis, staphylococcus pyogenes aureus, and a brown tetracoccus. Crookshank concludes that none of these bacteria are peculiar to vaccine lymph; "there was no bacterium constantly present in human and calf vaccine, and there was not one which could be regarded as the contagium. To sum up, most of them were well known saprophytic bacteria, and some were identical with bacteria commonly found in suppuration."

The experiments of Carstens and Coert (1878) show that the specific virulence of vaccine lymph is destroyed by ten minutes' exposure to temperature of 54 degrees C. And the writer's experiments (1879) show that various disinfecting agents tested—chlorin, sulphur dioxid, nitrous acid—destroy the infective virulence of lymph dried upon ivory points in about the same proportion as is required for the destruction

of some of the best-known pathogenic bacteria. But this does not prove that virulence depends upon the presence of a living microorganism, however probable this appears, for certain toxalbumins are likewise destroyed by a correspondingly low temperature and by the action of various chemie disinfectants.

Nikolsky (1892) obtained from the base of the pustules of smallpox a motile, liquefying, spore-producing bacillus which when introduced into the peritoneal cavity of rabbits is said to have given rise to a pustular eruption; the bacillus was recovered in cultures from these pustules. Grigorijew (1889) in three cases found a small bacillus, twice as long as thick, which slowly liquefied gelatin, and did not coagulate milk. Besser (1893) gives an account of the microorganisms found in the pustules of variola and adds to the list a bacillus found by himself in a single case. This does not grow in gelatin at the room temperature and is more slender than the bacillus of Grigorijew.

The results of the researches of Martin (1891) have been reported by Ernst (1893). He obtained various bacteria from the lymph of vaccine vesicles, and among these was a bacillus which he believed to be the specific infectious agent. This he was able to cultivate upon the surface of sterilized blood-serum of the ox, at 37 degrees C., and his cultures of the ninth generation are said to have produced typical cowpox when inoculated upon calves. He says: "The material 'takes' with the same certainty as the lymph from the vesicle. From the vesicles produced by it upon the calf I have vaccinated a number of children, in every case inducing vaccinia of the most perfect type." He also says with reference to his cultures: "These cultures, however, were not pure, but contained quite a variety of bacteria. In every instance the blood-serum was liquefied." As to the morphology he says: "The bacterium varies in form according to the various conditions of its nutritive environment and the consequent rate of its development. The most constant and prevalent form is a short, fine bacillus with rounded or nearly square ends. Those parts of the culture where the nutriment is apparently exhausted show the same bacilli in short chains, longer bacilli, and bacilli much enlarged at one end or the middle, as if in preparation for spore formation." As Martin's cultures were not pure we have no evidence that his successful inoculations were due to the particular bacillus which attracted his attention. Possibly a microorganism of another class was also present and was carried over from one culture to another. Ruete and Enoch (1893) have also reported successful vaccinations in the calf with a micrococcus which they cultivated from vaccine lymph.

Buttersack (1893) as a result of his researches arrived at the conclusion that there are numerous minute elements in vaccine lymph which do not stain and are sometimes arranged in chains. The subsequent researches of Landmann (1894) and others indicate that the supposed microorganisms of Buttersack are non-living albuminoid granules, artificially produced by his method of investigation. This view is confirmed by the investigations of Dräer (1894).

Guarnieri (1892), Monti (1894), Piana and Galli-Valerio (1894), and Clarke (1895), have observed ameboid microorganisms in the pustules of variola and in vaccine lymph which may prove to be the specific infectious agent in this disease. These are

described by Guarnieri under the name cytorycetes variolæ and cytorycetes vacciniæ. According to Clarke these ameboid parasites belong to the sporozoa. E. Pfeiffer (1895) has studied this parasite by inoculations into the cornea of rabbits, guinea pigs and calves.

Wassermann has recently (1895) reported his failure to obtain microorganisms in cultures from the variola pustules. He says: "At the suggestion of my highly honored chief I have made a bacteriologic examination of the variola pustules in cases 1, 2 and 4. Herr Geheimrath Koch had the kindness to inform me that he himself formerly in numerous cases, in which he made a similar investigation, had constantly found the contents of the pustules sterile. This I am able to verify from my own investigations. Naturally it is necessary to work with aseptic precautions. For this purpose the surface of the pustules was cleaned with alcohol and ether, and the contents then withdrawn with a capillary pipette. In this manner I obtained material from the pustules in all stages of their development, not only serum but also pure pus. This was cultivated upon human blood-agar, serum-agar, serum, and dextrin-serum-agar, both under aerobic and anaerobic conditions, but all of these culture media remained sterile, no microorganisms grew."

In certain cases of hemorrhagic smallpox Koch found constantly in the contents of the pustules a streptococcus—probably *S. pyogenes*—which no doubt represented a mixed infection.

That none of the bacteria which have been cultivated from vaccine lymph have anything to do with its specific virulence is indicated, not only by the fact that the inoculation of pure cultures of these various microorganisms gives a negative result, but also by the fact that vaccine lymph when mixed with glycerin after a time becomes sterile, so far as these microorganisms are concerned, without losing its power to produce a typical result when tested upon a susceptible individual. Copeman, has shown that such admixture, after a time, destroys the vitality of the micrococci and other bacteria present in the lymph, and that virus preserved in this way until it is sterile, as proved by culture experiments, is even more active than when first obtained. Copeman's conclusions have been confirmed by the independent observations of Cambon and Ménard, of Prof. Straus and others. And this method of preserving lymph is coming into general use. It has the manifest advantage of excluding the pus cocci and thus preventing the unpleasant complications which result from inoculating these pathogenic micrococci at the same time with the vaccine lymph. No doubt the excessive tumefaction, erysipelatous inflammation and ulceration which often result from vaccination are chiefly due to inoculation with these micrococci and especially with *staphylococcus pyogenes aureus* and *streptococcus pyogenes*. According to Prof. Straus glycerinated lymph which when fresh gave numerous colonies of various bacteria, including especially *staphylococcus pyogenes albus* and *aureus*, at the end of fifty to sixty days was found to be absolutely sterile. This method of excluding extraneous microorganisms should be employed by future investigators, who will thus have the advantage of conducting their experiments with a, presumably, pure culture of the vaccine microbe.

It seems to me, also, worth while to make some

experiments to determine whether successful vaccination can not be made, with such lymph, by a method which would insure the exclusion of bacteria from the locality into which the vaccine virus is introduced, thus giving an aseptic result. This would be readily accomplished if subcutaneous injection of the glycerinated virus could be substituted for the usual method of superficial scarification. That this may be possible is suggested by the experiments of Chauveau. In a paper published in 1877, eleven years after the publication of the report of the famous commission of which he was president, he says:

"When, in place of inserting the vaccine virus into the rete mucosum of the skin, we cause it to penetrate by way of the subcutaneous connective tissue, the virus manifests its action by two kinds of positive effects common to the three species" (man, horse and cow) "a more or less pronounced local tumefaction is developed, and the subjects acquire the vaccinal immunity exactly as if they had been vaccinated in the classic way."

The experiments of Raynaud (1877) led him to a similar conclusion. He says: "As regards the vaccinal pustule: The evolution of this pustule" (bouton) "is not necessary in order that immunity may be induced. This is produced after a subcutaneous inoculation, even when the development of the vaccine pustule is prevented."

Having briefly reviewed the evidence relating to the presence of microorganisms in the virulent material by which variola and vaccinia are transmitted from one individual to another I must now invite your attention to the second subject included in the title of my paper, viz.: *Scientific researches relating to the production of artificial immunity from this disease.*

In Jenner's "Inquiry," published in 1798, he gives an account of the observations and experiments which led him to the conclusion that cowpox results from the transfer of infectious material from "the heels of a horse affected with the grease"; and that when transmitted to the human subject, by contact in milking with the pustules upon the "nipples of the cows," "the person who has been thus affected is forever secure from the infection of the smallpox; neither exposure to the variolous effluvia, nor the insertion of the matter into the skin, producing this distemper." We now know that Jenner was mistaken in his inference that vaccination protects from smallpox during the lifetime—"forever after"—of the individual. It is generally recognized by physicians that the protection afforded is not absolute and that it is not permanent. Hence the necessity for revaccination, after an interval of several years, when smallpox is prevalent in a community. The fact that a single attack of smallpox is not always protective would lead us to expect that the immunity from vaccination would not be absolute, and experience shows that in every smallpox epidemic a certain number of persons who have been vaccinated fall victims to the disease; but experience also shows that the mortality among the vaccinated is very much less than among the non-vaccinated. The London Board of Health, from thirty returns sent to them—not selected—has given the following table:

	Number of Cases.	Deaths.	Percentage of Deaths.
Natural smallpox in the unprotected	1,731	361	20.85
Smallpox after smallpox	58	22	37.92
Smallpox after vaccination	929	32	3.44

The gradual loss of immunity from vaccination, as determined by revaccination, is shown in the following figures, which are given in a recent (1894) paper by Biedert. In the year 1889 smallpox was introduced into Hagenau, and twenty-one cases occurred. The physician charged with that duty revaccinated all of the school children with the result given below:

Age.	Number Vaccinated.	Successful.	Per cent.
6 to 7	288	94	33.0
7 to 8	292	187	63.8
8 to 9	222	161	72.5
9 to 10	221	176	80.0
10 to 11	306	273	85.8
11 to 12	413	367	88.6

We may remark in connection with this table that in Germany vaccination is compulsory, and all children must be vaccinated before the September of the year following their birth. All scholars who have not had an attack of smallpox must be revaccinated when 12 years old.

Questions relating to the practical application and results of Jenner's method of prophylaxis do not come within the scope of the present paper. But we must give some attention to a question of great scientific interest, which has been repeatedly investigated by the experimental method and upon which, nevertheless, divergent views are still held by members of the profession who have made a critical study of this evidence. The question is whether cowpox and horsepox are modified smallpox, as maintained by those who accept the evidence of successful inoculations, afforded by the experiments of Gassner, Ceely, Badcock and others, or whether these diseases are quite distinct and independent of each other as maintained by Chauveau, Fleming, Crookshank and others, who give reasons for believing that this evidence is unsatisfactory. The arguments in support of this last-mentioned point of view are so concisely stated by Fleming¹ that I shall take the liberty of quoting a considerable portion of his letter to the editor of the *Lancet* (Nov. 20, 1886). He says:

"For many years now, the medical profession in this country seems to be generally agreed that human variola and cowpox are one and the same malady, the latter being merely smallpox modified through transference to the bovine creature. In books, letters and lectures there is evidence of this belief, and the latest proof of its existence is to be found in the Harveian Oration recently delivered by Dr. Pavy, in which we find the following statement: 'It may now be regarded as an accepted conclusion that vaccine lymph is the virus of smallpox, modified by transmission through the cow.' If it be not rank heresy to throw doubts on a conclusion accepted by such high authorities in human medicine as Dr. Pavy represents, will you kindly allow me, a very humble student of animal medicine and comparative pathology, to dissent from this generally accepted conclusion, and to express strong doubts, or even entire disbelief, as to the one malady being merely a modification of the other. The question would not, perhaps, be of so much moment had not at least three serious accidents resulted from carrying the above conclusion into practice; and as more disasters may yet be due to the same notion, I submit that it is high time the supposed facts upon which it is based should be examined in order that the truth may be arrived at. The

most notable authority for the statement made by Dr. Pavy, in this country at least, was my old friend, the late Mr. Ceely, of Aylesbury, who reported that he had succeeded in producing cowpox by inoculating a cow with smallpox matter. But it must be remembered that he, at the same time, was experimenting with vaccine lymph, and the great probability is that he employed the latter when he thought he was using the former. At any rate, he never afterward succeeded in repeating his presumed success, though his subsequent trials were made under the most favorable conditions. The last attempt was undertaken 'not long ago, and only a short time before his death. On that occasion twelve heifers were purchased by the local government board and lodged in the Brown Institution, where they were inoculated by Dr. Klein, under the supervision and direction of Mr. Ceely; and though smallpox matter was literally poured into the incisions and the greatest care was observed throughout, yet cowpox was not developed in any of the animals. Similar failures have attended all other attempts, when these have been made openly and by two or more individuals. I may allude to those of the French commission, which included some of the most distinguished members of the medical profession in Paris, with the able veterinary surgeon, Chauveau, as operator; and the Italian commission, whose labors were carried on at Turin on a large scale and for a long time. All in vain, however, for smallpox could not be converted into cowpox, and the conclusion arrived at was in direct opposition to that which Dr. Pavy asks us to accept.

"Dr. Pavy speaks of the smallpox virus becoming attenuated in the cow, and that this attenuation manifests itself as cowpox. But if inoculation of the former produces the latter, then I contend it is not attenuation, but absolute and permanent transformation of the most startling and complete description, and such as can not be effected with any virus or microbes known. We are required to believe that by one remove of human smallpox—most infectious, fatal and generally eruptive disease—to the cow, we have produced a non-fatal disease, which can only be transmitted by inoculation, with an eruption quite localized at the points of inoculation, and otherwise widely different in its clinical and pathologic features, especially with regard to the eruption. Most astonishing of all, however, is the circumstance that this modified or attenuated smallpox, when carried back to its original soil in mankind, never resumes its original characteristics; no matter though it be carried through countless generations of human beings, it remains forever in its transformed condition. This does not happen with an attenuated virus, nor can any virus, by any artifice of man, become so utterly changed. Again, we all know how readily vaccine lymph, when inoculated in the calf or cow, will produce vaccinia. As I have pointed out, all attempts to develop the latter by inoculating these animals with variolous matter have resulted in failure, when made by those most competent to achieve success, if this were possible."

In support of the opposite and generally accepted point of view, I may be permitted to quote from an abstract of a paper by Copeman,¹ read before the Epidemiological Society of London, April 9, 1893:

"Whatever doubts might attach to some, especially

¹ Geo. Fleming, LL.D., Principal Veterinary Surgeon of the Army.

¹ S. A. Moulton Copeman, M.A., M.D., Medical Inspector, Her Majesty's Local Government Board, etc.

of the earlier attempts, and to those in which there was a suspicion of concurrent retro-vaccination, he was firmly convinced that Badcock, Ceely, Thiele and others in the past, as well as Voight, King, and above all Haccius, within the last ten years had repeatedly succeeded in transforming the lymph of typical variola into the best vaccine by successive transmissions through the bovine organism. In the earlier terms of such series it retained much of the virulence or activity of variola, but was even then essentially changed in being no longer communicable otherwise than by actual inoculation.

"In the cases on which the Lyons school relied in their denial of such transformation of variola into vaccinia the lymph or pus had not been absorbed and consequently was in no way modified, but the very same matter that had been inserted in the calf being afterward inoculated into the child naturally reproduced unmitigated smallpox.

"Haccius' experiments were, however, absolutely conclusive and unimpeachable, proving that vaccinia was but a modification of variola consequent on its cultivation in the cow."

The results obtained by Haccius and Eternod, which Copeman accepts as conclusive, are stated by the authors referred to as follows:

"In the first place, we affirm, that after having inoculated calves with variola virus, from seven different sources, and obtained from cases more or less grave, we have obtained every time, after the second or third generation"—*i. e.*, the second or third successive inoculation—"pustules which differed in no way, in their appearance, from the vaccinal pustules originating from cowpox.

"Our experiments show that the result of inoculations varies according to the method employed for introducing the virus. Scarifications and denudations alone have given useful eruptions, while incisions and subcutaneous punctures, such as are usually practiced, have given no result, or have only given rise to small red nodules, not suitable for propagation.

"It results from these facts that the inoculation of human variola in bovine animals causes two kinds of eruption, one which may be propagated and the other which can not.

"The eruption which can be cultivated does not give at the outset a vaccinal pustule having all of the typical characters. It requires, in general, to be transmitted through several successive generations in order to acquire them."

With reference to the successful results obtained by Badcock and by Ceely, we quote from a paper in the *British Medical Journal* (Nov. 26, 1881) by Dr. Hodgson, as follows:

"Although often failing afterward, it was Mr. Badcock's good fortune to have a first success. Obtaining from the late Sir (then Mr.) Cordy Burrows some lymph from a primary case of human smallpox, he inoculated a cow with it, and produced (in the judgment of Dr. Willis and Mr. Burrows) such perfect vaccine vesicles, that he has induced therefrom to vaccinate his own baby, and with the result again satisfying the medical men that genuine vaccine pocks occurred on the little boy's arm. From these, in turn, a supply of lymph was obtained, and was propagated on other children, uniformly with the same results; many other medical men taking part in the proceedings, or using the new lymph in their practices.

"Mr. Badcock's enthusiasm carried him forward, and led him, notwithstanding many failures and disappointments, to incur considerable expense in keeping up a stock of cows on which to continue his experiments. For twenty successive years did he persist from time to time, as opportunity offered, procuring through medical men fresh supplies of variolous matter, and using it on the cows. Altogether, he practiced on two hundred cows.

"Several of the two hundred animals he inoculated repeatedly. In only thirty-seven instances were satisfactory vaccine pocks considered to result; indeed, in four of these, they were not so finely developed as to encourage a transference from them of their contents. Consequently, the total number of cases in which typical vaccine pocks were produced, and which were considered eligible for vaccinating from (during the twenty years' experiments), was thirty-three. These successful cases were watched, in different stages, by various medical men, many of whom were public or practical vaccinators highly qualified to decide on their merits; and the lymph so obtained has been circulated throughout the civilized world. It continues to be held in high esteem in Brighton, where the three public vaccinators have each of them received gifts from the government three several times for the high standard of their vaccinations.

"The late Mr. Marson used Mr. Badcock's lymph for many years, and so did the late Mr. Ceely. The latter and Mr. Badcock commenced their experiments in the same year, unknown to each other; and Mr. Ceely, having succeeded twice only himself, afterward visited Brighton, and, having satisfied himself of the thorough reliableness of Mr. Badcock's doings, then ceased personally to experiment further—the more readily so, in consequence of the arduousness of his other occupations as a country hospital surgeon and general practitioner.

"Sir Thomas Watson and Dr. Bristowe, in their text-books on the practice of medicine, have both accepted Ceely's and Badcock's investigations, as furnishing the true bearing of cowpox to smallpox; and, as long ago as 1857, in the ponderous 'Blue-book' on vaccination, compiled under the superintendence of Mr. Simon, he thoroughly does the same. These are extracts from his report. 'Researches, subsequent to Jenner's, have settled this part of the question. It has been made matter of familiar experiment that the infection of smallpox may be communicated, by inoculation, from man to the cow, producing vesicles which present the physical characters of cowpox; and that the lymph from these vesicles, if implanted in the skin of the human subject, produces the ordinary local phenomena of vaccination, from which lymph may be transferred to other unprotected persons, all of which human beings will diffuse no atmospheric infection, and will afterward themselves cease to be susceptible to smallpox. The people thus protected are so, because the process has really given them smallpox of the most mitigated kind. The merit of this discovery belongs in the first place, to Gassner, in 1801; and, of corroborating it, in 1840, to Ceely and Badcock. The last mentioned has, during the last seventeen years, again and again derived a fresh stock of vaccine lymph from cows thus artificially infected by himself; has vaccinated with such lymph more than fourteen thousand persons, and furnished supplies of it to more than four hundred medical practitioners.'

The time at my disposal will not permit a more extended review of the experimental evidence; but in view of the positive results already referred to I believe we are justified in accepting it as a demonstrated fact that cowpox and smallpox have a genetic relation and that cowpox may be induced by inoculations with smallpox virus. The negative results which have so frequently attended such inoculations can not be accepted as establishing the contrary view. While this question could only be settled definitely by experimental evidence, we may call attention, as corroborative of the conclusion reached from an examination of this evidence, to the support which it receives from the demonstrated fact that both in man and in susceptible lower animals inoculations with the virus from either source confer immunity from the pathogenic action of the other. This cross immunity, so far as we now know, does not occur in infectious diseases which are not genetically related. Another significant fact is the frequency of cowpox in England at a time when smallpox was prevalent in that country, and its comparative infrequency since, as a result of vaccination, the prevalence of the disease has been greatly restricted.

The genetic relation of smallpox and horsepox is established, indirectly, by the experiments of Jenner and others, which show that inoculations of the virus of horsepox, or "grease," will cause the development of typical pustules of cowpox in bovine animals, and that from these a vaccine virus may be obtained which gives rise to typical results in man. Chauveau says that the horse "has a special aptitude to the natural or spontaneous development of the vaccine disease." Its special susceptibility is shown by the fact that a generalized vaccinal eruption, corresponding with that of natural horsepox, not infrequently results from cutaneous inoculations and also from intra-venous injections of vaccine virus. Such injections, according to Chauveau, "not only confer immunity, but quite frequently give rise to an exanthematous vaccinal eruption, the exact *fac simile* of the natural malady."

The experiments of Copeman, Reed and others, show that the monkey is also susceptible to vaccination and that after a successful vaccination it has acquired an immunity from the specific pathogenic action of the vaccine virus.

Reference has already been made to the experiments of Chauveau and of Raynaud, which show that vaccinal immunity may be produced by the subcutaneous injection of vaccine virus. Raynaud has also called attention to the fact that after such inoculations, as well as after vaccination by the usual method, the nearest lymphatic gland is considerably enlarged. The idea occurred to him that the specific infectious element might be retained in these enlarged glands, but he failed in obtaining any positive results from vaccinations with the juice of such enlarged glands. He also had negative results in subcutaneous inoculation made with lymph obtained from the lymphatic vessels between the point of vaccination and the nearest glands. But several grams of such lymph injected directly into the circulation of a horse caused an eruption of horsepox. In his summary of the results of his experiments Raynaud says: "It is then possible, finally, to detect traces of virulence in the lymphatic system, between the place of inoculation and the nearest lymphatic gland. Beyond this gland it is not found. This circumstance seems to indicate that the

glands may be concerned in the disappearance of virulence and the appearance of immunity, two facts simultaneous and correlative."

That immunity may be induced in the calf by intra-venous injections of small quantities of vaccine virus appears to be demonstrated by the experiments of Straus, Chambon and Ménard (1890). Chauveau had previously shown that the horse may be made immune by such injections.

Both Chauveau and Raynaud obtained negative results from their experiments with the blood of vaccinated animals. In a single experiment made in 1877 Raynaud obtained what appeared to be a positive result in a calf into the veins of which he had injected 250 grams of blood from another calf which had been vaccinated six days previously and in which the vaccinal eruption was fully developed. This animal proved to be fully immune, but subsequent experiments did not give a similar result and Raynaud abandoned the view, which he at first entertained, that immunity in this case was due to the transfusion of blood from a vaccinated calf. More recent experiments, however, seem to show that by the transfusion of a very large amount of blood from a vaccinated calf immunity may be induced. The experiments of Straus, Chambon and Ménard gave a successful result when the amount of blood transfused was as much as five or six kilograms.

Béclère, Chambon, and Ménard (1896) report that in their experiments the vaccinal eruption was considerably modified, in the calf, by subcutaneous injections of serum from an immune animal when the total amount injected was from 800 to 1,500 c.c.; also that lymph from the modified vaccinal eruption was attenuated, as regards its specific virulence. That complete immunity is not produced by the subcutaneous or intravenous injection of amounts varying from 50 to 1,000 c.c. is demonstrated by the experiments of Chauveau, of Raynaud, of Kramer and Boyce, of Beumer and Peiper and of the authors above mentioned.

The successful experiments of Prof. Straus and his associates lead them to conclude that the undiscovered "vaccine microbe" is present in the blood, in very small quantity during the period of eruption—at which time the blood was obtained which served for their experiments. A different explanation of the immunity resulting from the transfusion of so large a quantity of blood suggests itself as more probable, in view of recent additions to our knowledge relating to the production of immunity by antitoxins. If the immunity induced in the experiments referred to was due to the introduction of the vaccine microbe the result would not be likely to depend so largely upon quantity. A microbe capable of self-multiplication, if present in the blood transfused could scarcely fail to be in sufficient numbers to cause general infection when from 250 to 1,000 c.c. of this blood is injected into the veins of a susceptible animal. But in the experiments referred to immunity was not established unless a considerably larger quantity of blood was transfused. The experiments of Béclère, Chambon and Ménard (1896) show that blood collected from a vaccinated heifer some time after the complete dessication of the vaccinal eruption possesses immunizing properties. These results are confirmed by results obtained by Major Walter Reed, Surgeon U. S. A., in experiments on monkeys, made at the Army Medical Museum. Dr. Reed's experiments also show that a considerable

quantity of serum is required in order to establish a complete immunity from the specific pathogenic action of vaccine virus. When the quantity was insufficient a partial effect was noted, the vaccine vesicle appearing at a later date after vaccination, and in some cases showing an imperfect development.

Béclère, Chambon and Ménard have given the following summary of the conclusions reached by them, as a result of their experiments:

"1. The serum of a vaccinated heifer collected ten to fifteen days after vaccination, after the virulent period, possesses immunizing properties.

"2. The immunizing action of the serum of the vaccinated heifer is very rapid. The subcutaneous injection of a sufficient quantity, made immediately before vaccination by numerous sub-epidermic inoculations, modifies the subsequent development of the vaccinal eruption and may cause its almost complete abortion."

"4. The rapidity of the immunizing action of the serum of the vaccinated heifer, compared with the tardy immunity which follows the subcutaneous inoculation of vaccine lymph, demonstrates that the serum owes its immunizing properties to soluble substances and not to the presence of the microbes (still unknown) of vaccinia."

The experimental evidence heretofore referred to seems to support the conclusion last stated and experiments made by the present writer in 1892 show that the soluble substances upon which immunity depends when brought into contact with vaccine virus neutralize its specific virulence—presumably by destroying the vitality of the vaccine microbe. The positive results reported in my paper published (1892) in the *Transactions of the Association of American Physicians*² have since been confirmed by Kinyon and by Reed.

¹ The writer in 1893 made a series of experiments "upon unvaccinated children in two orphan asylums in Brooklyn, with a view to ascertain whether blood serum from an immune calf, or from an individual who had recently suffered an attack of smallpox, if injected into the subcutaneous tissues at the time of vaccination, would prevent the development of a characteristic vaccine vesicle. In these experiments from 1 to 5 c.c. of the serum supposed to contain an antitoxin of smallpox was injected near the point of vaccination, or, in some instances, into the other arm. The result was negative, even when serum was used from an individual who was just convalescent from a severe attack of smallpox. But it may be that a different result would have been obtained if a larger quantity of blood serum had been used, or if it had been injected into the circulation instead of into the subcutaneous tissues. More recent experiments by Kramer and Boyce (1893) and by Landmann (1894) also show that small amounts of serum from immune calves (5 to 10 c.c.) do not prevent the development of the vaccine vesicle; and that blood serum (35 c.c.) from one who had suffered a recent attack of smallpox did not have any noticeable effect upon the development of a confluent case of smallpox in a child 5 years of age (Landmann)."

(Quotation from the writer's work on *Immunity, Protective Inoculation in Infectious Diseases and Serum-Therapy*. Wm. Wood & Co., New York, 1895.)

² The following extract from my paper entitled "Practical Results of Bacteriological Researches," gives details of the experiments referred to:

"These experiments were made with the kind assistance of Dr. Wm. E. Griffiths, of Brooklyn, who has for many years been engaged in the production of vaccine virus, and consequently is an expert in the vaccination of calves and in recognizing vaccinia in these animals.

"Upon visiting Dr. Griffiths and making known to him my desires, I found him quite willing to assist me, and also that he had recently vaccinated, and consequently immune, calf in his stable. This animal had been vaccinated in numerous places upon the abdomen and thighs fourteen days previously. The vaccination was entirely successful, and a large number of quills had been charged from the vesicles which formed. At the time of my visit for the purpose of collecting blood-serum from this animal, dry crust still remained attached at the points where vaccination had been practiced two weeks previously. On the 28th of April I collected blood serum from a superficial vein in the hind leg of this calf. This blood was placed in an ice chest for twenty-four hours, at the end of which time the clear serum was drawn off in 'Sternberg's bulbs.' Four drops of this serum were placed in each of two small, sterilized, glass tubes; in one of these we placed three quills charged with fresh vaccine lymph from a calf. At the end of an hour the quills were removed, after carefully washing off in the serum the lymph with which they had been charged. In the other tube we mixed with the four drops of blood serum an emulsion made from a fragment of a perfectly fresh vaccine crust from the arm of a child; this was crushed upon a piece of glass and rubbed up with a little of the same blood-serum. The two tubes were now placed in an ice chest for twenty-four hours, at the end of which time the contents were used to vaccinate a calf purchased for the purpose. Dr. Griffiths carefully shaved the thighs of this calf and scarified each thigh in several places, as he is accustomed to do in vaccinating for the propagation of lymph. The contents of the tube con-

The experimental evidence recorded appears to me to indicate that the immunity resulting from vaccination, or from an attack of smallpox, is due to the presence in the blood of the immune animal of a substance which destroys the variola microbe, rather than to an antitoxin capable of neutralizing the toxic substances developed during the growth of this hypothetical microbe. As already stated, my own experiments show that direct contact with blood-serum from an immune animal neutralizes the specific virulence of vaccine virus, and I infer that it does so by destroying the vitality of the contagium vivum present in such virus. The antitoxins, as a rule, have no germicidal action; but we have experimental evidence which shows that immunity from the pathogenic action of certain microorganisms may depend upon the presence of a germicidal substance in the blood of the immune animal. Thus Gamaleña, Pfeiffer and others have shown that in animals which have an acquired immunity against infection by the spirillum of Asiatic cholera and against spirillum Metchnikovi there is a decided increase in the bactericidal power of the blood-serum.

If, as we suppose, the immunity resulting from vaccination is due to the presence of a germicidal substance in the blood the source of this substance is a question of great scientific interest, and its solution might lead to important practical results in the treatment of smallpox. Possibly this substance is elaborated by the lymphatic glands and may be obtained from the enlarged glands of a recently vaccinated calf in greater concentration than from the blood-serum of the same animal. This can only be determined by a series of carefully conducted experiments.

Already a limited number of clinical experiments have been made with blood-serum from an immune animal; but the results have not been very encouraging. The ascertained fact that very large amounts

taining lymph from the quills were rubbed into the scarified places upon one thigh, and the contents of the tube containing the emulsified crust into the other. On the 8th of May, nine days after the vaccination, the calf was carefully examined, and it was ascertained that the result of the vaccination was entirely negative.

"Evidently it was necessary to make a control experiment before we would be justified in ascribing this negative result to a neutralization of the virus by some special substance present in the blood serum of an immune calf. Possibly the blood of a non-immune calf might also, after an exposure of twenty-four hours, neutralize the specific virulence of vaccine lymph. The control experiment was made as follows:

"On the 9th day of May we collected blood from a vein in the leg of a non-immune (not vaccinated) calf; this was placed in the ice-chest for twenty-four hours, and the following day clear serum was collected in Sternberg's bulbs. Three quills, charged with fresh lymph from a calf, of the same lot as those used in the previous experiment, were placed in four drops of this blood-serum in each of two small glass tubes. As in the previous experiment, the lymph was washed from the quills at the end of an hour, and the tubes were placed aside in the ice-chest. At the end of twenty-four hours the serum in these two tubes was used to vaccinate the same calf which had served for the previous experiment. Several points were scarified upon the left thigh and upon the left side of the abdomen, which were carefully shaved for the purpose.

"At the same time the animal was vaccinated upon the right thigh and upon the right side of the abdomen with virus mixed with the blood serum from the immune calf. This serum, collected in Sternberg's bulbs on the 28th of April, had since been kept in the ice-chest. One hour before the vaccination four drops of this blood-serum were mixed with one drop of liquid lymph, which had been recently collected by Dr. Griffiths in a capillary tube from a vaccinated calf. At the same time three quills charged with bovine lymph were immersed in four drops of the same blood serum from immune calf. As stated, the animal was vaccinated upon the right side of the abdomen and upon the right thigh with this virus, which had been exposed for one hour to the action of blood-serum from an immune calf. The serum containing the liquid lymph was rubbed into the scarification on the right side of the abdomen, the serum containing lymph from the quills into the right thigh. On the 19th of May, eight days after the vaccination, the animal was carefully examined by Dr. Griffiths and myself, and the following results noted: Upon the left thigh and left side of the abdomen the vaccinations, from quills in non-immune blood-serum after twenty-four hours' contact—were entirely successful, the scarification being surrounded by characteristic vesicles and covered by characteristic crusts. Upon the right thigh, vaccinations from quills immersed in blood-serum from immune calf for one hour—and upon the right side of abdomen—vaccinations with liquid lymph mixed with blood-serum from immune calf, the result was entirely negative. Several of the scarifications had entirely healed; others were covered with a dry scab which was easily detached and under which the scarification was healing without any appearance of vesicles such as surrounded the scarifications upon the left side."

of blood-serum are required to produce immunity in a healthy animal appears to indicate that a specific therapeutic effect can not be expected from the subcutaneous injection of a few cubic centimeters of serum, or even from the transfusion of several hundred cubic centimeters. As already mentioned, the experiments of Chaveau, of Raynaud, and of Prof. Straus and his associates, upon calves, agree in showing that the immunizing dose of blood-serum is several kilograms, and that the transfusion of less than 1,000 grams usually has no appreciable effect.

In two cases of smallpox treated by Dr. Elliott, with serum collected by Kinyon (1895) the result is supposed to have been favorable, although one of the patients died. This patient received in all 60 c.c. of the serum, in doses of 15 c.c., injected subcutaneously. In the second, non-fatal case, 105 c.c. was administered in the same way "during a period of forty-eight hours." Dr. Elliott says: "There was no effect on the eruption in the first case. It is my opinion that the vaccine serum will shorten the course of variola if given in the papular stage of the eruption. The vaccine serum does modify the variolous eruption, even in the pustular stage, but does not shorten the attack. The most serious objection to its application is the largeness of the dose, 15 to 30 c.c., which leads the patients to object to its use."

Landmann (1894) injected 25 c.c. of blood-serum, from an individual who had recently recovered from an attack of smallpox, into a child, 5 years of age, suffering from an attack of confluent smallpox. No noticeable effect was produced.

Auché (1873) had previously reported a negative result from the subcutaneous injection of serum obtained from recent convalescents—6 c.c. in one case and 18 c.c. in another.

Béclère, Chambon and Ménard, in their recently published paper, to which we have already referred, say that they have made clinical experiments to determine the therapeutic value of blood-serum from an immune animal in seventeen cases of variola, and that the results of these experiments will shortly be published. Possibly their report may be more favorable than we now anticipate.

In view of the large quantity of blood serum required to produce immunity, and, by inference, to have a specific therapeutic effect in smallpox, it is evident that an effort should be made to obtain the immunizing substance in a more concentrated form. Already, Dr. Reed has made some preliminary experiments in this direction at the Army Medical Museum, and he has ascertained that a dried precipitate from the serum of an immune calf, obtained by the method of Brieger and Cohn, contains a substance which neutralizes the action of vaccine virus, when brought into contact with it before vaccination. A comparative test showed that the dried precipitate from the serum of a non-immune calf has no such effect.

The conclusions reached and suggestions made in this paper may be summarized as follows:

1. Smallpox, cowpox and horsepox are genetically related, being different manifestations of the same infectious disease in different genera of animals (Man, Bos, Equus).

2. The specific infectious agent of variola and of vaccinia has not been demonstrated. The extended experimental investigations which have been made indicate that it does not belong to the class of microorganisms known as bacteria.

3. Various bacteria are commonly found in the lymph from vaccine vesicles, obtained either from bovine animals or from man. Among these are the well-known pus cocci, and these micrococci are probably largely responsible for the erysipelatous inflammation and other unpleasant complications which frequently result from vaccination with such lymph.

4. Lymph preserved in glycerin after a time becomes sterile so far as the presence of bacteria is concerned, without losing its specific virulence.

5. Immunity may be induced by subcutaneous inoculation of vaccine virus, without the development of a vaccine vesicle; and it is probable that the subcutaneous injection of lymph preserved in glycerin would give protection without any of the septic complications so common as a result of vaccination by the usual method.

6. The blood-serum of immune animals contains a substance in solution which destroys the specific virulence of vaccine virus when brought in contact with it.

7. This substance is not present in sufficient amount to make the blood-serum of immune animals available for the production of immunity in man (or for the treatment of variola?). But it may perhaps be obtained in a concentrated form by chemical methods, and in that case would be likely to prove useful, and possibly specific as a therapeutic agent in this disease.

8. The immunity resulting from the subcutaneous injection of vaccine lymph, like that resulting from vaccination in the usual manner is gradually developed and is not complete until the eighth day,³ depending, no doubt, upon a multiplication of the infectious agent in the body of the susceptible animal. On the other hand, the immunity resulting from the transfusion of a large amount of blood serum from an immune animal to a susceptible animal is an immediate result of such transfusion.

VAGINAL HYSTERECTOMY FOR FIBROIDS OF THE UTERUS.

BY FRANKLIN H. MARTIN, M.D.

PROFESSOR OF GYNECOLOGY POST-GRADUATE MEDICAL SCHOOL, SURGEON TO WOMAN'S HOSPITAL. CHICAGO.

HISTORICAL.

Vaginal hysterectomy is closely associated in its early history with cancer of the uterus. Greig Smith says, that it is probable that incision of the uterus was practiced by the ancient Greeks, but it is certain that it was subsequently forgotten. Soranus, in his book of "Diseases of Women," who lived in Rome a century before Christ, describes the operation as a surgical procedure for prolapsus. The first authenticated description of vaginal hysterectomy subsequent to this was given by Berengarius, of Bologna, in 1507.

In 1560 Andreas A Cruce performed vaginal hysterectomy. J. Schenck a Grafenberg 1617 (Senn) relates a number of cases in which the uterus was removed through the vagina in whole or in part by ignorant persons who had not the faintest ideas to the difficulty or of the extent and gravity of the operation. In 1792 Saunonier removed an inverted uterus below a ligature. Hildanus 1616, Wrisberg 1785, Bernhard 1821 reported cases of accidental or unintentional removal of uteri by the vagina by careless midwives and others. Intentional removal of the uterus by surgeons have been reported by Zwinger, Vicussen, Baxter, Faivre, Alexander, Hunter, Joseph Clark and Jackson. (Senn.)

The real history of vaginal hysterectomy begins when it was deliberately planned and executed for the relief of definite pathologic conditions. To J. M. Langenbeck in 1813 belongs the credit of opening this page of history. He removed the uterus by enucleation, using neither clamps nor ligatures and his case recovered and lived many years. The post mortem demonstrated to his incredulous critics the truth of his claim. Sauter, Jan. 28, 1822; Elias von Siebold, April 19, 1823; Holscher, Feb. 5, 1824; Elias von Siebold, again July 25, 1825; Langenbeck again Aug. 5, 1825; Recamier, July 26, 1829; Langenbeck, again Aug. 18, 1829; Roux, Sept. 20 and Sept. 25, 1830; Recamier, again Jan. 13, 1830; Blundell, Oct. 16, 1830. Siebold 1831, Delbach 1839 are the bold pioneers who followed the lead of Langenbeck in Europe. From 1839 to the revival of Czerny in 1878 there are no records of European cases. In America, however, a few cases were put on record during this long interval. Palmer Dudley reports that Dr. John M. Esselman, of Nashville, Tenn., in September, 1834, removed an inverted uterus by means of the ligature, his patient recovering. This same surgeon repeated the operation successfully in August, 1843, for an inverted uterus containing a fibroid. This is the first vaginal hysterectomy for fibroids of the uterus I find recorded. The first vaginal hysterectomy for cancer deliberately undertaken and successfully executed in this country was performed by Dr. Paul F. Eve, of Augusta, Ga. April 16, 1850. (*Am. Journal of Medical Science*, 1858.) Dr. L. C. Lane, of San Francisco, operated for cancer Nov. 11, 1878, and at a later date in the same year on a second case for cancers. Both cases recovered. Lane executed this operation independently of Czerny, who revived the operation in Europe by performing his first operation April 12, 1878, or seven months earlier than Lane.

From the revival of Czerny and Lane, with the dawn of clean surgery, the operation of vaginal hysterectomy became a legitimate operation. In less than twenty years it has made wonderful strides. It has been performed thousands of times by hundreds of operators, and has, undoubtedly, been the means of adding many years to the sum total of human life.

VAGINAL HYSTERECTOMY FOR FIBROIDS.

It is argued that a patient suffers less real shock, on an average, when submitted to a vaginal hysterectomy than when operated upon by the abdominal route. The only rational explanation that can be forwarded to account for this fact is that the intestines and the peritoneum are not subjected to exposure to the air in the vaginal route, nor are they subjected to the handling which they are liable to receive in the abdominal operations. While in our improved methods, the abdominal contents are exposed and handled to a small degree compared to former times, at the same time we can not help but recognize that there is less shock after a perfect vaginal hysterectomy than after an abdominal hysterectomy in cases of like severity. A vaginal hysterectomy avoids the abdominal scarring which so many patients dread as a brand of mutilation which must be carried through life after an abdominal operation. Many patients I find have this wholesome dread to such a degree that they seem to be no comparison in their minds between the two operations. An abdominal operation contains all the horrors of a most dreaded affair, while

vaginal operation with no sign of mutilation left, is contemplated like a normal labor with dread but resignation. An abdominal scar, it is true, will frequently become the seat of considerable irritation and rarely the seat of severe neuralgic pains. There is always, too, the remote possibility of ventral hernias developing in an abdominal scar. It is also claimed, by not a few operators, that safer and more satisfactory drainage can be obtained, when it is required, through the vaginal route than by the abdominal. However, as soon as we undertake to do a vaginal hysterectomy on anything but the smallest kind of a fibroid, we are hampered by the narrow limits in which we have to do our work, and, therefore, if the tumor is of considerable size, the extra time its proper removal from the vagina requires, off-sets what is gained by non-exposure of the abdominal viscera. So that the rational surgeon must discriminate here, as everywhere else in surgery, and select the operation which best suits the individual case. If he has a small fibroid, or a large fibroid with relaxed ligaments and a large, roomy vagina, he should select the lower route; whereas, if he has a large fibroid high in the pelvis, or a small one with a narrow, contracted vagina and rigid tissues he should do a laparotomy and remove the tumor from above.

Methods.—Vaginal hysterectomy for fibroids may be divided into two grand divisions: 1, removal of the uterus and its fibroid masses as a whole without division, or vaginal hysterectomy proper; 2, removal of the uterus and its accompanying fibroid development in piecemeal or morcellment.

1. VAGINAL HYSTERECTOMY PROPER.

Indications.—Vaginal hysterectomy proper for fibroids must of necessity include only the smallest tumors, or at best fibroid uteri with long, slender subperitoneal projections. The operation is often the ideal method of treating small multiple fibroids, which are so frequently the seat of severe uterine pain and excessive hemorrhage. Fibroids of considerable size may frequently be treated by vaginal hysterectomy, when the uterus is low in the pelvis and the vagina is large and the tissues loose. It is an easy matter to turn a complete vaginal hysterectomy for fibroids into a morcellment should any unlooked for enlargement manifest itself.

TECHNIQUE OF VAGINAL HYSTERECTOMY PROPER.

The patient should be prepared with the same care and manner that I have described in my article on preparatory treatment for laparotomy. Special care should be maintained to render the vaginal tract and external genitalia aseptic. The patient should be anesthetized with ether. She should be placed in the exaggerated lithotomy position with the limbs supported by some mechanical device which will hold them firm and for any required length of time. Otherwise, they should be supported by strong skilled assistants on either side, who will also hold the vaginal retractors. Immediately before the operation begins a nurse or a third assistant should thoroughly scrub the external genitalia and the vagina with green soap. This should be thoroughly rinsed off, and the parts should be thoroughly washed with 95 per cent. alcohol and finally rubbed with 1 to 1,000 bichlorid of mercury and then douched off with sterilized water. Moist sterilized towels are placed around the field of operation. The operator takes a seat at the foot of the table on a small stool. At his right are his instru-

ments with the surgical nurse to do his bidding. At his left is the nurse who superintends the irrigator of sterilized water and handles the sponges.

Operation.—Two small vaginal retractors, with short broad blades, are introduced and held by the assistants so as to retract the anterior and the posterior vaginal wall and expose the cervix uteri. The cervix is grasped by a light pair of vulsellum forceps with four teeth, the uterus rapidly dilated by first introducing a small dilator and then a large strong one, until its interior can be reached and thoroughly explored with a sharp curette. The uterine cavity is thoroughly curetted and then rendered aseptic by washing out with a solution of 1 to 100 bichlorid of mercury. It is then loosely filled with sterilized gauze. Through the cervix, by means of a curved needle, is passed a strong double handling string of braided silk, and this is tied over the os uteri in such a way as to close the canal. The vulsellum forceps are now removed and the strong silk ligature is henceforth employed as

FIGURE 1.

a means of handling the uterus. The uterus is now drawn well down by making strong tractions and the cervix drawn back so as to expose the anterior utero-vaginal fold. With a curved scissors the mucous membrane of the vagina at its attachment to the uterus anteriorly is penetrated and the incisions carried to the right and to the left following the utero-vaginal junction, until the incisions meet posteriorly and the uterus is completely severed from the vault of the vagina (Fig. 1). The assistant now grasps the handling string and makes downward and backward traction, while the operator with the index fingers of both hands carefully separates the bladder from the anterior surface of the uterus. If there are any firm bands connecting the two organs, they should be severed with scissors near their uterine attachment, always keeping the point of the scissors against the firm uterine tissue. As soon as the utero-vesical fold of the peritoneum is reached with the fingers the two fingers should be separated laterally, so as to detach the bladder from the anterior surface of the broad

ligament, and also for the purpose of pushing the ureters, which pass under the broad ligaments near the cervix, well to the sides of the pelvis.

The assistants now draw the cervix forward and the operator separates the uterus from its posterior attachments and the two fingers penetrate through the peritoneum into Douglas' cul-de-sac. The fingers are then separated laterally tearing the peritoneum in that direction. A large dry gauze sponge, with a string attached, is pushed through this opening and spread out above the uterus. The broad ligaments and the appendages are then rapidly examined. The peritoneum in front of the uterus between it and the bladder is now torn through and the broad ligaments are the only attachments left between the uterus and the patient. If the uterus is not too large and the broad ligaments are loose and the vagina large, one pair of strong forceps will secure each broad ligament. The uterus is drawn well down and the operator slips his index finger of the left hand behind the left broad ligament and crowds the appendages toward the uterus until he can hook the finger over the ligament outside of the appendages. With the uterus held well down and steadied by one of the assistants, the other assistant holding the bladder well out of reach

forcing, a small pair of straight hemostatic forceps may be applied to the projecting free end of the severed tissue. Occasionally it is not practicable nor safe to include the whole broad ligament in one pair of forceps because of its width and bulk, while again it may be difficult to place the forceps on the whole ligament at once, because of a too narrow vagina or a highly situated uterus with short ligaments. Here the bulky base of each broad ligament should be clamped first, with short stout catch forceps and the ligaments severed up to within a short distance of the forceps' bite. The uterus then can be drawn down and the remaining portion of the broad ligaments can be secured in one pair of forceps on each side. The last forceps are placed on the uterine side of the first forceps. The forceps are now held by the assistants to their respective sides of the vagina with their handles separated in such a manner as to act as lateral retractors. The sponge is removed from the pelvis and the toilet of the peritoneal cavity is made by drying it with sponges on holders. The posterior retractor is now inserted and the operator seeks the edge of the peritoneum which covers the bladder, grasps it with a catch forceps and draws it down and with a running stitch of antiseptic catgut attaches it to the upper end of the anterior vaginal wall. An anterior retractor is now inserted and the edge of the peritoneum covering the rectum is attached to the upper end of the posterior vaginal wall in the same manner. This insures hemostasis of the anterior and posterior vaginal edges, and covers an otherwise uncovered gap of connective tissue space.

Drainage.—The forceps are widely separated, two narrow retractors hold open the vagina anteriorly and posteriorly, a square piece of sterilized iodoform gauze two feet wide is placed with its center over the vulva, and with a large pair of dressing forceps its folded center is carried well into the vagina beyond the ends of the forceps, so as to form a bag. It is then loosely packed with strips of sterilized iodoform gauze and the edges of the filled bag is left projecting several inches from the vulva. It is folded over the vulva. The handles of the clamp forceps are wrapped in gauze. A liberal supply of absorbent cotton is placed over and around the forceps and over the perineum and vulva, and all held in place by three small perineal bandages, one passing between the handles of the forceps and the other two outside of the forceps handles.

VAGINAL HYSTERECTOMY BY MORCELLEMENT.

Indications. Vaginal hysterectomy by morcellement may be done for fibroids of considerable size, the limit of maximum size on which the operation may be safely undertaken depending on the skill and experience of the particular operator. The writer does not favor the operation where the uterus is too large to deliver easily after bisecting, preferring to undertake such cases by the abdominal route. The operation is now performed every day, however, by an increasing number of skillful men on fibroids of every size, even on tumors reaching well above the umbilicus.

Polk, a firm believer in morcellement for fibroids, lays down the following indications: 1. Whenever the mass is largely within the pelvis, especially if it is fixed therein by adhesions. 2. Whenever the mass

FIGURE 2.

by a long narrow bladed retractor, the operator with his right hand slides a strong pair of Byford's clamp forceps (Fig. 2) over the broad ligament, the posterior blade following the lead of the index finger, which is still holding the ligament, until they include its whole width, and project half an inch beyond its upper edge when they are closed and locked. The jaws of the forceps should be examined carefully to see that they include all the tissues necessary, and that it compresses all portions sufficiently. The locks of the forceps should be securely tied. With the index finger guiding the scissors, the clamped ligament is now severed close to the uterus. If the uterus is not too large and the right broad ligament is long the organ can be delivered as the next step and when delivered the right broad ligament may be clamped with ease outside of the vulva. If this is possible the clamp should be applied outside of the appendages and the uterus cut away. Frequently, however, the uterus can not be delivered until the other clamp is applied and the ligaments severed. Under such circumstances the forceps should be carefully applied exactly like the first one and the ligaments divided with the scissors from below upward while the assistant makes slight traction on the uterus until the organ is free, when it is delivered. The broad ligament forceps are carefully examined now, to be sure that each is doing all the work required of it, viz., including the whole ligament in its grasp and finally compressing every portion sufficiently tight to maintain hemostasis. Should any portion need rein-

is soft and, therefore, compressible as in myoma and fibrocystoma. 3. In all other cases where we have a patient in good condition whose pelvis is shallow, where the vaginal canal is roomy, and in whom the evidence of a pyosalpinx above the pelvis brim are absent. Péan, Segmond, Richelot, Jacobs, Henrotin and others do not make suppurating appendages a contraindication to this method of operating.

TECHNIQUE.

Cases with Uterus only Double its Natural Size.—

In these cases the technique is very similar to that for simple vaginal hysterectomy, with the exception that the uterus is bisected with an antero-posterior incision.

Step 1: The vagina is severed close to the cervix, as in ordinary vaginal hysterectomy, and the uterus denuded until the posterior and anterior cul-de-sacs are opened.

Step 2: Grasp the anterior lip of the cervix on either side with strong bullet forceps or two well embedded handling strings, and making strong traction split the anterior wall of the uterus with strong scissors with the posterior blade guided by the uterine canal

FIGURE 3.

(Fig. 3). When the scissors have reached the limit of exposure of the uterus the edge of the split uterus at the highest point of the incision should be grasped by the bullet forceps, and with this new grasp the uterus should be drawn down still farther and the splitting process continued. When the uterus is usually movable or the broad ligaments unusually long, sometimes at this point the partially split uterus is completely anteverted and the fundus is delivered. As a rule, however, whenever it is necessary to split the uterus at all in order to remove it, the bisecting must be carried to completion.

Step 3: When the bisected uterus is well drawn down, the increased movability of the organ in consequence of being in two pieces enables one to clamp the broad ligaments with one, or at most two forceps, and the respective halves are removed. After one side has been cut away it is an easy matter to clamp and remove the opposite half.

Step 4: Finish operation and apply drainage as in simple vaginal hysterectomy.

Variations of Procedure.—If it is convenient it

is often better to attempt to clamp the broad ligaments immediately after opening the two cul-de-sacs, in order to save the patient as much blood as possible. When it is not possible to clamp the whole broad ligament, the base of the ligaments with the uterine arteries may be secured. As a preliminary every precaution should be observed to render the cavity of the uterus aseptic.

Cases with Uterus More than Double Its Normal Size.—In these cases the uterus must be removed by piecemeal. In order to accomplish this so as not to make a horrible failure, a thoroughly systematic course must be observed by one skilled in the details of pelvis surgery and surgical emergencies. No two cases are alike. Consequently no two operations are ever identical.

Step 1: Circular incisions around the cervix, after first grasping the anterior and the posterior lip of the cervix with strong forceps. The uterus is denuded anteriorly and posteriorly and the posterior

FIGURE 4.

cul-de-sac is opened. An attempt is then made to enter the anterior cul-de-sac.

Step 2: Clamp forceps are now placed on the base of each broad ligament high enough to include the uterine artery and its branches, and the ligaments are cut nearly as high as the point of the clamp.

Step 3: The cervix is split into halves by a lateral incision on the line of the uterine canal with strong scissors or a knife (Fig. 4).

Step 4: With the anterior lip well drawn down and firmly held, the posterior lip is drawn well down and amputated. The remaining stump of the posterior half of the uterus is firmly grasped in forceps, keeping the uterus well down in the field of operation.

Step 5: If the uterus is not too large at this point a single clamp forceps may be placed on the remaining portion of the broad ligament.

Step 6: With hemostasis well secured from this point on the splitting of the uterus is continued and morcellation is proceeded with by amputation of first one-half or a portion of a half and then the other, sever-

ing the broad ligaments by degrees until by piecemeal the whole uterus is removed. Care should be maintained to have a secure hold of the uterus with forceps at some point besides the point of amputation at all times, in order that it may not slip out of the field of operation. As soon as the uterine mass has been reduced sufficiently so that it may be delivered it should be removed. Care must be exerted to secure all large subperitoneal masses which from their situation might by carelessness be accidentally separated from the tumor and escape beyond the reach of the finger or forceps. As the morcellement progresses a finger in the posterior cul-de-sac from time to time learns facts of value to the operator.

Remarks. The care of the forceps and the care of the vaginal and peritoneal edges, after this modified operation, is identical to that after the simple operation. The toilet of the operation field and the drainage is the same. If adhesions exist they must be carefully separated. If the anterior cul-de-sac is elevated so that it can not be entered before amputation is commenced, amputation should be proceeded with and the uterus gradually drawn down until the cul-de-sac can be opened.

Accidents to be avoided.—Wounding of the bladder or intestines and clamping one or both carelessly are accidents which must be carefully guarded against in vaginal hysterectomy of any kind. Severing of important blood vessels before they are securely clamped is another annoying accident, because of the tendency of the unsecured blood vessels to retract into the loose connective tissue of the broad ligament, where they will continue to bleed out of reach of hemostatic forceps. To avoid this accident great care should be observed to securely clamp all tissues before severing, and if there is the slightest doubt about the security of any portion of the divided ligament after it has been cut a second clamp should reinforce the first. To avoid clamping the ureters the forceps should not be applied to the base of the broad ligament until the bladder is thoroughly separated from its anterior surface, until the finger can sweep between it and the broad ligament to the sides of the pelvis. This insures the pushing of the ureters out of the reach of the forceps. This same maneuver insures the integrity of the bladder also. If the bladder is found so adherent at any portion that it is not readily separated with the finger, scissors should be employed to dissect it from the face of the uterus or tumor, great care being observed to avoid wounding the bladder with the scissors by keeping the point of that instrument against the uterus. By following the imperative rule of separating the bladder early and keeping it out of the field of operation by the use of an anterior retractor, it will never be wounded. To avoid wounding the rectum the same care should be observed in entering the posterior cul-de-sac as is exerted in opening the anterior one. If one carelessly opens this pouch, it is an easy matter to strip the peritoneal covering of the bowel posterior to the cul-de-sac and miss entering the peritoneal cavity entirely; while by ignorantly pursuing this false track the rectum may be penetrated. To avoid this embarrassing predicament *stick to the uterus*. If one does strip off a portion of the uterine peritoneum it will do no harm and the rectum is safe.

USE OF LIGATURES FOR VAGINAL HYSTERECTOMY.

By some operators ligatures are employed for secur-

ing hemostasis instead of clamps. In simple, uncomplicated cases ligatures may be employed with ease. In morcellement, where high and excessive manipulation is required the ligatures are impracticable because of the difficulty of applying them, and because of the difficulty of preventing them from becoming loosened by the subsequent manipulation of the parts. When ligatures are employed they prolong the convalescence if they are left long and allowed to ulcerate away. The time required for the accomplishment of that act is from twelve to forty days. During all this time it requires great diligence on the part of the attendant to prevent infecting of the ligatures; in fact, it is seldom prevented. An offensive vaginal discharge bears evidence of the fact, until the ligatures are finally discharged. If ligatures are employed and cut short, with the idea of burying them, it frequently happens that they become infected, even when the greatest care is observed to preserve cleanliness. The reason for this is the necessity for drainage in almost all of these cases. The method of drainage makes the wound practically an open one. Hence the danger of some portion of the otherwise buried ligatures becoming infected. Once infected long months of pus discharge from vaginal fistula is the sequel. This is all avoided when hemostasis is secured by strong forceps, because the means of hemostasis (the forceps) are removed in forty-eight hours, and nothing is left of a foreign nature which may become infected.

AFTER-TREATMENT OF VAGINAL HYSTERECTOMY WITH CLAMPS.

Shock is treated on the lines laid down in my article of two weeks ago. I must, also, refer the reader to that article for the detail treatment of the bowels and care of the patient as regards drink, diet, etc. The bladder is emptied every eight hours with a catheter until the forceps and the first drainage is removed. The catheter should be employed oftener if it is necessary. The nurse employs an aseptic glass catheter with a small nozzle which will run the urine off into a bottle. The urethra is carefully exposed before the catheter is introduced and thoroughly wiped off with a saturated solution of boracic acid.

Forceps.—The locks of the forceps are carefully tied at the time they are put on to avoid accidental unclaspings of their blades. The handles are kept covered with sterilized gauze. If it gets soiled at any time it is changed. At the end of twenty-four hours all but the principal forceps are removed. The string securing the lock is cut, the lock unfastened carefully, the blades opened enough to loosen their grasp on the tissues and then they are carefully removed. At the end of forty-eight hours the main forceps are removed in the same manner. If the tissues in any particular case showed unusual tendencies to bleed at the time of the operation I allow the forceps to remain twenty-four hours longer. When the large forceps are removed they should be opened widely before an attempt is made to withdraw them, and then they should be brought out with a backward motion in order to avoid catching the tissues with the projection on the posterior blade.

Dressing. If the external portion of the drain becomes soiled with accidental discharges of urine or excessive drain fluid it should be removed and replaced with a new external pad of loose sterilized gauze as often as is necessary. Twelve hours after the last

forceps are removed about one-third of the external gauze drain should be removed and a fresh pad of gauze placed over the vulva. In twenty-four hours another third should be extracted, and in twenty-four hours more, or sixty hours after the last forceps are removed, all of the balance should be taken out. When the last gauze is removed an external irrigation should be employed of 1 to 5,000 bichlorid solution followed by a plain water irrigation. A small sterilized iodoform drain should now be carried carefully about three inches into the vagina on a strong pair of dressing forceps, and the end of the drain allowed to protrude from the vagina. Over this is placed an antiseptic absorbent pad. In twenty-four hours this drain is removed and then eighty-four hours after the last forceps are removed, and the peritoneum has had ample time to close, the first vaginal douche is given.

Douches.—This douche must be given with extreme care by a nurse who understands all the responsibility she is entrusted with. The douche point must be made of glass, bulbous, with openings directed only at right angles to it. The patient should be placed on her back at the edge of a bed with feet supported on two chairs. A Kelly pad should be under her buttocks. The reservoir containing sterilized water of a temperature of 105 should be placed but eighteen inches above the patient's hips, in order to have but slight pressure. The nurse after thoroughly preparing her hands, inserts two fingers into the vagina about two and one-half inches, and between the fingers extending to within one-half inch of their extremities is inserted the douche point. The water is turned on with every precaution employed to secure immediate and free return current. The douche is repeated in this way, the nurse introducing the fingers and douche point a little further each time until the vault of the vagina is reached, every twelve hours until the sixth day from the removal of the forceps, when 1 to 5,000 bichlorid of mercury solution may be substituted for the plain douche, always following the bichlorid douche by a plain one. It must be obvious why I insist on the great care in employing this douche. The peritoneal cavity is expected to close in a few hours after the gauze is removed. Frequently, there is no doubt, it is closed off a few hours after the operation is finished. Notwithstanding this tendency to early closure of the peritoneal cavity, carelessness in employing the first few douches, if free return stream was not provided and great pressure employed by placing the reservoir high, might result in breaking up the union of the tissues and fill the abdominal cavity with the fluids and *débris* of the vaginal tract. After each douche the vulva should be covered with an antiseptic pad. After each urination or movement of the bowels the external parts should be douched off with sterilized water and the antiseptic dressing renewed.

Getting Up.—Patients manifest a desire to get up earlier after vaginal hysterectomy than after abdominal operations. There is less prolonged reaction in the way of nervous exhaustion as there is less immediate shock with the vaginal operation. I allow my patients to begin to sit up on the twelfth to fifteenth day. They can leave the hospital from the twentieth day onward.

Results.—I have performed vaginal hysterectomy for uncomplicated fibroids of the uterus forty-one times; one death resulted from the operation. At least twenty of these cases were performed with clamps as the exclusive means of securing the broad liga-

ments. In the balance of cases ligatures of silk alone or ligatures reinforced with forceps were employed. The majority of my cases were small tumors. In two cases there was a troublesome hemorrhage within twelve hours after the operation, from the vaginal edges, which was, however, easily controlled by applying small catch forceps to the bleeding point. I opened the bladder in one of my early cases; it was subsequently closed in a secondary operation. I have never had secondary hemorrhage or the slightest oozing after removing the clamps. I have never had a vaginal hernia. I have never had a troublesome vaginal fistula. In one case where ligatures were used and left long they did not come away for nearly six months.

Dr. Edward Garceau of Boston, to whose writings on vaginal hysterectomy I am indebted in preparing this article, gave in his excellent paper on "Vaginal Hysterectomy as Done in France," in the *American Journal of Obstetrics*, Nov. 3, 1895, the following table of operations with their results, to which list I add my own cases. A list like the subjoined can not be said to represent the average mortality of the operation because it includes the work alone of the most experienced operators in this line in several countries. At the same time it must be remembered that this represents pioneer work in a comparatively new procedure.

Operator.	Cases.	Deaths.
Mayer	1	0
Péan	200	4
Jacobs	22	2
Mangiagalli	8	0
De Ott	100	0
Carle	22	0
Calderini	1	0
Bockel	3	0
Routier	6	0
Richelot	43	1
F. H. Martin	41	1
	447	8

This gives a mortality of 1.7 per cent.

SELECTIONS.

Amount of Carbonic Acid Exhaled from the Lungs.—The *Gaz. degli Osp. e delle Clin.*, March 28, describes an apparatus invented by Mosso for this purpose. Other kinds of apparatus are very complicated and not portable, while this one is comparatively simple and can be easily carried about. It consists of a rubber mask to put over the mouth and nose, terminating in a tube which carries the air through two Muller valves to a rubber bag, connected with which is the register and a water valve, ending above in a T-shaped tube. One end of this tube is connected with a syringe that pumps up the air through the connecting tubes, which contains an aqueous solution of barium hydrate. By removing the tubes the amount of carbonic acid is easily found. The proportions in several half-hour tests were, 11 grams of carbonic acid in 187 liters of air; 10 grams with 172 liters and after a meal, 228 liters with 14 grams of acid. In sleep one trial showed 193 liters with 13½ grams. The inventor proposes to make a comparative study of the elimination of carbonic acid after eating, fatigue and various illnesses.

Abdomino-Perineal Method of Extirpating a Rectal Cancer.—Some members of the Paris Société de Chirurgie have been experimenting with a new method of removing cancer of the rectum, which has as yet only been performed on one living subject, and who succumbed a few days after to accidental dyspnea. The large intestine is drawn out through an opening in the abdomen and a couple of ligatures made, four centimeters

apart, above the extreme limit of the neoplasm, and a section made between. The ends are ligated again and covered with iodoform gauze. An incision is then made in the recto-vesical perineal pocket, and the rectum below the section detached as much as possible. A circular incision is then made at the anus, after which the entire rectum is drawn up and out through the perineal incision which is then entirely closed. An artificial anus is then made from the end of the intestine above. This method is adapted to those cancers which extend from the anus twelve to fifteen centimeters upward, where the rectum can still be made to slide on the neighboring organs. If the growth prevents this slipping of the rectum it is beyond any operation. *Bulletin Médical*, March 29.

Varicella Fatal Through Intercurrent Laryngitis. Drs. Marfan and Halle have reported two cases of severe laryngitis, one preceding, the other accompanying varicella, in *Revue mensuelle des Maladies de l'Enfance*. In both cases it was "Löffler absent," in the second case, the infant being feeble, the attack was fatal. The first case, an infant of 3 years, was brought under observation after an illness of three days' duration. The voice was hoarse and respiration difficult, with the supra- and infra-tracheal depression. The fauces were reddened, but in other respects showed no abnormal condition. After twenty-four hours an injection of 20 cubic centimeters of antidiphtheritic serum was made and cultures taken. The same evening the first vesicles of varicella appeared upon the surface. The laryngeal symptoms increased, and on the following day called for tracheotomy. The first cultures from the throat and later ones made directly from the trachea by way of the canula demonstrated the absence of the Löffler bacillus. After three days the canula was removed and the case went on to complete recovery.

The second case occurred in a weekly infant of 9 months. When brought to the hospital with marked symptoms of laryngeal obstruction, a profuse confluent varicella eruption was noticeable. The throat was free from false membrane and was scarcely reddened, while no trace of vesicles was found upon the buccal mucosa or upon the pillars and uvula. This case was also regarded as probably one of primary laryngeal diphtheria complicating varicella, and an injection of antitoxin was made by Roux. Cultures taken at the same time subsequently showed the absence of diphtheria bacilli. Death occurred on the seventh day from acute diarrhea and bronchopneumonia. The autopsy showed a small, round, deep ulcer at the posterior part of the margin of the right vocal cord.

These two cases of varicella of the larynx determined a stenosis, giving the clinical picture of a true croup, and are in the authors' opinion unique examples. The only case of varicella involving the larynx previously reported is that recorded by Boucheron in his thesis ("Étude sur les complications respiratoires de la varicelle et relation d'un cas de varicelle du larynx," Paris, 1893), in which the affection took the aspect of a spasm of the glottis without symptoms of laryngitis. The case terminated fatally by suffocation during an access of the spasm. The authors conclude that involvement of the larynx in varicella occurs early, about or shortly after the appearance of the eruption, a point that serves to distinguish it from secondary and unrelated infections. Anatomically this laryngitis is characterized by small ulcerations, circular, few in number, seated usually upon the true cords. About these ulcers the mucous membrane may be the seat of hyperemia, more or less intense and extended. These two lesions explain the two forms under which the complication occurs, as is shown by the authors' cases on the one hand and by Boucheron's on the other.

NECROLOGY.

JOHN JOSEPH DALY, M.D., of Rahway, N. J., died April 11, in the forty-fifth year of his age. He was the mayor of that city and the day of his death was the anniversary of his last election to the mayoralty in 1895. He was born in Rahway in 1852, and was graduated from the Medical Department of the University of the City of New York in the class of '73. He practiced medicine and surgery in Rahway with much success. He was first elected mayor of Rahway in 1885, and was four times re-elected, and once defeated. He was city physician of Rahway for several years.

CLARENCE L. FITCH, M.D., died suddenly April 13, in New Haven, Conn., of heart disease. He was born in Walton, N. Y.,

38 years ago, and was graduated from the Dartmouth College in 1882. He had been in New Haven thirteen years and had built up a large practice. A widow survives him.

DR. ALEX. B. ERNST of Covington, Ky., died at his home April 21, from tuberculosis following repeated attacks of la grippe. Dr. Ernst was born in Covington, July 18, 1863, and his parents were one of Kentucky's most distinguished families. He was educated at Chickering Institute, Princeton College, and received his degree of M.D. from the medical college of Ohio in 1888. Dr. Ernst enjoyed a lucrative practice and was a most universal favorite among his associates and a much beloved physician to his patients.

J. B. K. MIGNAULT, M.D., of Detroit, Mich., April 25. He was born in Montreal, Canada, in 1817, and received his medical education at McGill College. In 1850 he went to Detroit after having practiced ten years in Mt. Clemens. After an active term of medical service during the rebellion he removed to Mt. Clemens and established mineral baths. In 1875 he returned to Detroit and retired from practice in 1882.

BOOK NOTICES.

Consumption: Its Nature, Causes and Prevention; with an outline of the Principles of Treatment, for all classes of readers. By EDWARD PLAYTER, M.D. Toronto: Williams Briggs, pp. 340.

We opened this book with an intention of glancing through it hastily, and ended in reading it carefully. It has been written in a clear, concise manner, and is so free from technical phrases that it will be easily comprehended by the non-professional reader. Indeed, it is one of the few books written on this subject that can be safely placed in the hands of the patient. Starting with a definition of consumption and a chapter devoted to the function of the lungs, a considerable portion of the work is devoted to the causation, giving the following among other causes: "The tubercle bacillus is an essential factor in the production of tubercular pulmonary consumption. The tubercle bacillus does not become a cause in the production of the tuberculous state, except in a special condition of the human body in what is termed a suitable soil. Persons with a defective respiratory action from any cause are more liable to have toxic substances formed in the body; and which probably influence the action of microorganisms present therein, including tubercle bacilli. The so-called soil for the pathogenic action of this bacillus in the lungs seems to be invariably furnished by persons with a defective breathing function as particularly evidenced by the 'outdoor' or 'pure air' treatment of the disease, with special lung expansion for increasing the breathing function. Particular stress is laid upon the belief that a defective respiratory function with the retention in the body of waste or excrete substances, and the toxic compounds generated thereby is the actual, immediate or exciting cause of consumption." Heredity, want of the natural body defenses, habits and conditions of life, the infectiousness and communicability of the disease, sources and dissemination of the bacilli, the *de novo* origin of the disease are discussed at length among the causative factors.

Part II is devoted to the consideration of the prevention of the disease, which is named as a special object of the book, being a public question which involves the eventual stamping out altogether, practically, of this most destructive of all diseases. This portion of the book should appeal, not only to the physician, but to every intelligent victim of the dread disease, and for this reason we believe it will be accepted as a book of instruction for our families in which consumption has already found its victim, or in which there is a marked predisposition to the disease.

A few pages are devoted to the climate and prevention, the book closing with a short chapter on a few general principles relating to the treatment.

THE

Journal of the American Medical Association

PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
 Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
 No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, MAY 9, 1896.

ANTHROPOLOGY AS A BRANCH OF MEDICAL EDUCATION.

Anthropology, as comprehensively defined by BROCA, is the science of man. Taken in its widest sense, it comprises not only anatomy, physiology, pathology, psychology, and the other studies usually included at the present day in the medical curriculum, but also archeology, ethnology, biology and allied subordinate sciences, that investigate man as an individual and in the aggregate, both specifically and in his relations to surrounding natural objects.

The study of man can not be separated from zoölogy, the science of all animal life, or of biology, which studies the functions of living beings, without giving rise to narrow, one-sided, and erroneous views. The study of the manifestations of intelligence in the lower animals, and the results attained by comparative anatomy and therapeutics, have thrown much light upon some of the most difficult problems in human pathology and clinical medicine. Pharmacology, indeed, may be said to lay its claims to recognition as a science principally upon physiologic investigations on the lower animals and upon practical deductions from results in the field of comparative medicine.

In a restricted and metaphysical sense, anthropology has been applied to the study of man in his relations to the Deity; but in the present consideration the term will be used only in its accepted scientific meaning, in accordance with the definition given above. Anthropology, in the first place, assigns man to his proper position in the scale of living beings, where he stands "the paragon of animals." It is true that structurally he can not be considered the peer of some of the inferior animals. He has not the physi-

cal strength of the gorilla, the rapid pace of the greyhound, the swimming power of the seal, the flying power of the bird or bat. His special senses are less keen, there are many animals which have superior acuteness of hearing, of sight or of tactile sense. His vitality, the ability to resist disease, to endure fatigue and hardship, are manifestly inferior to animals generally, speaking of them as they exist in their natural state. It is solely the extraordinary and excessive development of the cerebral hemispheres, especially in the anterior lobes, that places man in his elevated position in the scale of creation and separates him widely even from the most highly developed ape. There is also a manifest difference in the quality of the gray matter, as well as in the quantity, which of itself separates man from the anthropoid simians as from all other inferior animals, and to which due consideration should be given in discussing man's affinities and specific traits, and his claims to classification apart from inferior animals.

The question whether there was originally only one race of man or whether there were distinct types of mankind from the beginning, can be discussed more temperately at the present time than it could be at the period when NOTT and GLIDDOX wrote on "The Types of Mankind." Human slavery and the social problems arising from it, no longer invade our halls of science and disturb the philosophic calmness of debate. At present the weight of authority seems to be in favor of the theory of unity of origin. This is really in accord with the statement made by DARWIN himself, who says: "When naturalists observe a close agreement in numerous small habits, tastes and dispositions, between two or more domestic races, or between nearly allied natural forms, they use the fact as an argument that all are descended from a common progenitor, who was thus endowed; and consequently, that all should be classed under the same species. The same argument may be applied with much force to the races of man." This argument from analogy has considerable weight, and, at all events, encounters less opposition than it did a generation ago under different economic conditions.

Some three years ago, PROF. DANIEL G. BRINTON of Philadelphia, wrote a pamphlet on "Anthropology as a Science and as a Branch of the University Education" in which he made a strong appeal for the recognition of the claims of this science as a branch of instruction in our colleges. It would seem as if his arguments could be applied to our great medical schools with even more force than to the secular institutions. It would be a great gain to medical education if anthropology should be commenced in the preparatory course and concluded in a post-graduate course, after having been followed for the whole period of undergraduate study. In this way a systematic, comprehensive and consistent course could

be followed, which could be continued to any desired extent by those who felt themselves especially attracted to this science.

The first school of anthropology, according to DR. BRINTON, was founded by BROCA at Paris in the year 1876. This institution, beginning with five professors, now has ten, the demand for more extended instruction having steadily increased from its inception. It has very close relations to the medical course and the majority of its students are also students of medicine. A second school is now in operation in the same city, in connection with the Museum of Natural History at the Jardin des Plantes. A school has recently opened in Italy known as the Faculty of Anthropology in the University of Rome, under the special charge of PROFESSOR SERGI. There are departments of anthropology in the Universities of Munich, Berlin, Marburg and Buda-Pesth, and instruction is likewise given in this branch at Leipzig and a number of the other chief educational institutions of Europe. The University of Brussels has established a full chair of anthropology and a similar position exists in the Musée Polytechnique at Moscow. In the United States, regular courses on physical anthropology and ethnology have been given by DR. BRINTON, at the Academy of Natural Sciences in Philadelphia, since 1886. The University of Chicago and Clark University at Worcester, Mass., had also given instruction upon this subject, and Harvard University for many years has taught ethnology and allied branches, but up to 1892 no full professorship of anthropology has been established by any educational institution in this country. Since DR. BRINTON wrote, the University of Chicago has established a titular chair and will shortly commence systematic instruction in this department. Last year the University of Pennsylvania appointed DR. BRINTON to a newly created position in the Faculty, Professor of American Archeology and Linguistics, in recognition of his services to this particular branch of science.

The method submitted by DR. BRINTON, as the best one to be pursued by teachers of anthropology, is the subdivision of the study into four associated departments of nearly equal importance:

Somatology.—This studies the physical nature of man, his anatomy, physiology, and biology, so far as these bear on the distinctness of races, peoples and nations. Psychology, so far as it is an experimental and inductive science, belongs to this department.

Ethnology. This is in its methods, historic and analytic. It contemplates man as a social creature. It is more concerned with the mental, the psychic part of man, than with his physical nature, and seeks to trace the intellectual development of communities by studying the growth of government, laws, arts, languages, religions and society.

Ethnography.—This is geographic and descriptive in its plans of research. It studies the subdivisions and migrations of races, local traits, peculiarities, and customs; and confines itself to matters of present observation.

Archeology.—This comes in to supply the material, which neither history nor present observation can furnish. It pries into the obscurity of the remotest times and periods of man's life on earth and gathers thousands of facts, forgotten by historians and overlooked by contemporaries. Often these unconsidered trifles prove to be of peculiar value and furnish the key to the real life of ancient nations.

Necessary adjuncts to the systematic study of anthropology are properly equipped laboratories for practical observation and original investigation. Library labor consisting in courses of reading in the literature of the science, should also form a part of the assigned tasks of the student in this department.

Such a course of study as here outlined would prove especially attractive to those physicians, who take a broad and comprehensive view of the problems of disease from the biologic standpoint.

THE MONEY-COST OF A TYPHOID FEVER EPIDEMIC.

DR. CAMPBELL MUNRO, Medical Officer of Health for Renfrewshire, in his annual report for 1894 takes up the question of the pecuniary loss that follows a prevalence of infectious diseases. The epidemic of typhoid fever in Mid-Renfrewshire in 1893, caused 74 deaths out of 859 cases. As a first item in the bill of expenses, DR. MUNRO estimates that through loss of wages the community lost over \$16,000. The loss through the cost of the treatment of patients is placed at an average of \$25; DR. MUNRO has found that the average cost of a patient treated at the hospital was not less than \$40. On this basis the epidemic caused an expenditure of \$21,000 in treatment. The cost of funeral expenses is estimated at \$1,850, thus making for the three items of loss above enumerated, a total of \$37,850. The next item to be considered, the money-value of the lost lives, he calculates as follows:

"A quotation from the writings of FARR, the greatest authority on the subject, will best illustrate the position of the matter: 'As lands, houses, railways and the other categories in the income-tax schedules are of value, because they yield annual returns, so for the same reason, and on the same principle, the income of the population derived from pay of every kind, for professional or other services, and wages, can be capitalized; not precisely, it is true, unless the income of every person living were returned at least as nearly as incomes subject to income-tax; but sufficiently near to the true value to show that the value of the population itself is the most important factor in the wealth of the country. . . . The capitalization of personal incomes proceeds upon the determination of the present value, at any age, of the *future annual earnings* at that and all future ages.' The value to the community of an individual member is ascertained by deducting the capitalized future cost of subsistence of the individual from his cap-

itized future income. Proceeding upon these lines, FARR arrived at the conclusion that the 'minimum value of the population of the United Kingdom—men, women *and children*—is about \$800 a head; that is, the value inherent in them as a productive, money-earning race.' He estimated the value of the population of the United Kingdom, at the time he was writing, as equivalent to a capital sum of \$26,250,000,000, while the 'capital' of the country (using the term in its ordinary sense) amounted, according to Mr. GIFFEN'S estimate, to \$42,000,000,000.

"Adopting FARR'S figures as a basis for the calculation, I have made a rough estimate of the value 'inherent in' the persons who died in the course of this epidemic 'as a productive, money-earning race.' I find that it amounts to the very large sum of \$68,000 (nearly). So that the pecuniary loss to the community of Mid-Renfrewshire, arising in connection with the epidemic, amounts to the enormous total of \$105,000. A consideration of these figures may well suggest the reflection whether any investment is calculated to yield a better pecuniary return than the expenditure involved in the operations of the Public Health Department, which have for their main object the prevention of epidemics."

MISCHIEF-MAKING JOURNALISM.

In the same issue of our more or less esteemed contemporary, the New York *Medical Record*, in which it affected editorial ignorance of the AMERICAN MEDICAL ASSOCIATION, asking "What is it?" and in the same column is published a statement—"No Pay, No Work"—to the effect that "it has been decided by the Supreme Court of Illinois that the health authorities have no right to require physicians to report contagious diseases or births without pay," and, upon this obviously absurd proposition, proceeded to discuss the nice question: "Whether the physician, whose aim is the prevention as well as the cure of disease, is not morally bound to warn the community of danger when this can be done at a not unreasonable expenditure of time and labor," etc.—*more Bunsbii*.

The proposition was obviously absurd because, at least so far as Illinois is concerned—and the same is true generally of other States—the requirement is a statutory one and not, except in an executive way, a requirement of the health authorities. Nevertheless, and notwithstanding this absurdity, inquiry was at once made of the clerks of the three divisions, and of the official reporter, of the Illinois Supreme Court. The HON. ISAAC N. PHILLIPS, Official Reporter, replies: "No such decision by the Supreme Court of Illinois as that referred to in your letter of the 24th inst. has come to my knowledge." The clerks of the different divisions also assert that no such decision has been filed with them and that they "never heard of it before."

At this stage the JOURNAL had intended to ignore the matter, not anticipating that the statement would be accepted seriously elsewhere. But the current (May) number of the Cleveland *Journal of Medicine* shows what mischief the unfounded publication of the *Record* may work if still uncorrected. The Cleveland *Journal* says:

"An interesting fact apropos of the present discussion by the City Council [Cleveland] of a new health ordinance providing more stringently for the reporting of contagious diseases by physicians is noted in the *Medical Record* of February 22. [April 18]. The Supreme Court of Illinois has just decided that physicians can not be compelled to report on contagious diseases or to render any other public service without pay. This is the more remarkable because in many States there are valid laws compelling physicians to report births and deaths. It must be a peculiarity of Illinois law."

Our Cleveland contemporary is respectfully advised that this "peculiarity of Illinois law" need not embarrass the attempt to secure the new health ordinance in that city; that the "peculiarity" is only a figment of the *Record's* imagination; and that it will do well in the future to look to the carefully edited columns of this JOURNAL for authentic information rather than to the pages of a periodical whose insular prejudices recently betrayed it into making a boast of its ignorance concerning the representative medical organization of the whole country.

The *Record's* minor statement, to-wit: "That there is or was in existence in Connecticut a plan 'whereby the physician would receive twenty-five cents for each notification of a case of infectious disease or a birth,'" is thus contradicted by the veteran sanitarian and statistician, DR. C. A. LINDSLEY, Secretary of the Connecticut State Board of Health:

"Physicians have never been paid for reporting infectious diseases in this State. But they are paid twenty-five cents for each certificate of birth and death rendered to the town registrar, if rendered monthly as the law requires. The legal question of the power of the Legislature of Connecticut to authorize the enactment of ordinances requiring physicians to report infectious diseases without compensation was decided in the affirmative by the Supreme Court in 1887. See report of decision in Annual Report of Connecticut State Board of Health for 1889."

"EIGHTY PAGES IN THIS NUMBER."

Conspicuously displayed on its title page the New York *Medical Record* week by week announces the number of pages in each issue. That of last week reads "Seventy-six Pages in this Number"; that for the week before reads "Eighty Pages in this Number." The inference intended to be drawn is, of course, that these are the specified number of pages of reading matter in the respective issues. As a matter of fact, there were thirty-six pages of reading matter in each of these two numbers, and forty and forty-four pages of advertisements respectively, about one-fifth of which is advertising matter devoted to the interests of the commercial house by which the *Record* is owned. Without venturing to express an opinion on the relative merits of the two classes of matter, reading and advertising, still we can not refrain from speculating upon the mental caliber of the readers of that periodical who, as its editor evi-

dently thinks, can be gulled by such a specious pretence. The JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION is publishing nearly 40 per cent. more pages of reading matter in every issue than the *Record*—fifty pages as against thirty-six—and, owing to the size of type and page, fully twice the number of words. That the JOURNAL matter excels as much in quality as in quantity seems to be the verdict of a large and steadily increasing number of unprejudiced jurors.

THE JOURNAL TRAIN.

The JOURNAL train left Chicago at 12 o'clock on Sunday, May 3, by the "Big Four" road as advertised, in charge of MR. MCGINNIFF of that company. The weather was pleasant, the sun shone brightly, and the accommodations were excellent. Engine No. 193 pulled us into Cincinnati at 9:05 P.M., exactly on schedule time. Here we were turned over to the Queen & Crescent, and, as has been remarked by one individual, "Trouble began at this point." We had been informed, and the agreement was made accordingly, that no delay should occur; that our train should run through as a "special" from Cincinnati to Atlanta. Some of the party desired to know whether an opportunity would be allowed to take supper at Cincinnati, but as it was a "special" to run through without change, it was said not to be possible, and after waiting until 10:30 we were informed that it was not the intention to take our train out of the depot until the arrival of the Detroit "Medicine" train, under the charge of DR. MOYER, of Chicago, and DR. WHITMORE, of P. D. & Co. Their party consisted of about thirty-three people, who started over the "Monon" Route, but meeting with an accident were delayed somewhere in Indiana, and our party was compelled to wait for them until about 11:30 P.M. At that hour, becoming restless and impatient, and on representations made to the trainmaster in Cincinnati, the alleged superintendent of the Queen & Crescent Road, a certain MR. STEPHENS, was brought down to interview the passengers, and notwithstanding the desire of the party to proceed on their journey, he flatly refused to accommodate them in any particular. Not only that, upon representations having been made to him that the train should proceed, which by this time was composed of some of the most distinguished physicians of the Northwest and their families, he announced that the cars belonged to them, and that he would move them out of the depot when he got ready, or words to that effect. Arguments, persuasion and entreaties were of no avail to the all-powerful MR. STEPHENS, who finally becoming tired of the importunities, sent the train across the river to Ludlow, Ky., where they completed the allotted period of the detention and were finally joined by the delayed contingent as aforesaid. From

this time forward the train made an excellent run. We arrived in Chattanooga at 10:30 A.M., very tired, considerably disgusted and very hungry. We had a fair breakfast at Chattanooga, which tasted all the better, as some of our party had eaten nothing for twenty-four hours, thanks to the inhumanity of MR. STEPHENS. From Chattanooga we made a splendid run over the Southern Railway. The officers of that company made every effort to make the trip pleasant and speedy. We arrived in Atlanta at 3:30 P.M., where some of the JOURNAL party found the rooms which they had engaged at the Aragon Hotel already assigned to others. The originators of the trouble, including the alleged STEPHENS, were not extremely popular with any of the members of the JOURNAL party.

A number of physicians on the train made up their minds that they had learned something in the matter of travel over certain railroads, and that when it came to advising patients going South for the winter what line to take in order to have the most comfort and humane attention, they would know how to advise them. A more unfeeling and heartless treatment of passengers has seldom been witnessed than that received at the hands of MR. STEPHENS, of the Queen & Crescent.

The following is the list of passengers:

JOURNAL TRAIN LIST.

Dr. Wm. L. Allen, Davenport, Iowa; Dr. C. Abaly, Madison, Wis.; Dr. Jas. P. Boyd, Akron, Ohio; Dr. C. B. Burr, Flint, Mich.; Dr. John R. Brown, Indianapolis, Ind.; Dr. L. C. Cline, Indianapolis, Ind.; Dr. A. C. Cotton, Chicago, Ill.; Dr. D. W. Graham and wife, Chicago, Ill.; Dr. John B. Hamilton and wife, Chicago, Ill.; Mr. Wm. Whitford, Chicago, Ill.; Dr. D. B. Collins, Madison, Wis.; Dr. and Mrs. P. V. Carlin, Denver, Colo.; Dr. R. Beverly Cole, San Francisco, Cal.; Dr. D. H. Cunningham; Dr. Henry Day, Eau Claire, Wis.; Dr. W. B. Hill; Dr. Jos. Eastman and daughter, Indianapolis, Ind.; Dr. W. Eastman, Mineral Point, Wis.; Dr. H. Bert Ellis, California; Dr. and Mrs. D. S. Fairchild, Clinton, Iowa; Dr. L. M. Gregory, Stevens Point, Wis.; Dr. Alonzo Garcelon, Lewiston, Me.; Dr. J. B. Barber, Dunkirk, Ind.; Dr. T. C. Hood, Dana, Ind.; Dr. and Mrs. C. M. Hobby, Iowa City, Iowa; Dr. C. H. Hughes, St. Louis, Mo.; Dr. W. B. Hill, Milwaukee, Wis.; Dr. A. F. Jonas, Omaha, Neb.; Dr. Geo. F. Jenkins and wife, Keokuk, Iowa; Dr. J. V. R. Lyman, Eau Claire, Wis.; Dr. A. S. Lawbaugh, Opeckee, Mich.; Dr. I. N. Love, St. Louis, Mo.; Dr. Chas. McAllister, Iowa; Dr. W. D. Middleton, Davenport, Iowa; Dr. Donald Maclean and wife, Detroit, Mich.; Dr. E. E. Montgomery and wife, Philadelphia, Pa.; Dr. K. D. Mellier, St. Louis, Mo.; Dr. James T. Priestley, Des Moines, Iowa; Dr. Paul Paquin, St. Louis, Mo.; Dr. J. H. Ross, Kokomo, Ind.; Dr. G. William Reynolds and son, Chicago; Dr. E. R. Smith, Toledo, Ohio; Dr. N. Senn, Chicago; Mr. Enno Sander, St. Louis, Mo.; Dr. X. C. Scott, Cleveland, Ohio; Dr. G. W. Sloan, Indianapolis, Ind.; Dr. J. C. Shrader, Iowa City, Iowa; Dr. J. C. F. Thorne, Kokomo, Ind.; Dr. D. J. Townsend, Lehighville, Iowa; Dr. H. D. Thomason, Albion, Mich.; Dr. Fenton B. Turk, Chicago; Dr. Chas. True, Kankakee, Ill.; Mr. Chas. Truax, Chicago; Mrs. M. Watson Thornbury, Redfield, Iowa; Dr. B. F. Uran, Kankakee, Ill.; Dr. Lyman Ware, Chicago; Dr. G. V. Woolen, Indianapolis, Ind.; Dr. J. A. Work, Elkhart, Ind.; Dr. D. C. Wilson, Ironton, Ohio; Mrs. D. C. Wilson, Ironton, Ohio; Miss. V. M. Wilson,

Ironton, Ohio; Dr. P. A. Walling, Park Rapids, Minn.; Dr. J. E. Woodbridge, Cleveland, Ohio; Dr. B. M. Walrath, St. Paul, Minn.; Dr. Geo. W. Webster, Chicago; Dr. A. L. Wright, Carroll, Iowa; Dr. Wm. J. Younger, San Francisco; Dr. Henry B. Young and wife, Burlington, Iowa.

ELECTION OF OFFICERS.

As we go to press we learn by telegraph of the election of PROF. NICHOLAS SENN, of Chicago, to the Presidency of the Association for the ensuing year; GEN. GEO. M. STERNBERG, U. S. A., has been elected Vice-President. Members of the Board of Trustees: DR. E. E. MONTGOMERY, Philadelphia (re-elected); DR. JOSEPH M. MATHEWS, Louisville; DR. C. A. L. REED, Cincinnati; and DR. G. C. SAVAGE, of Nashville, to fill the vacancy caused by the death of DR. JAMES E. REEVES.

The annual addresses will be delivered by DR. AUSTIN FLINT, of New York, on General Medicine; DR. WM. W. KEEN, of Pennsylvania, on General Surgery, and DR. JEROME COCHRANE, of Alabama, on State Medicine.

The next annual meeting will be held in Philadelphia, the birthplace of the ASSOCIATION.

CORRESPONDENCE.

Dr. Reuben D. Mussey.

WILMORE, PA., April 29, 1896.

To the Editor:—I beg the privilege of thanking Dr. Hamilton, through the JOURNAL, for his article on the life of Dr. Mussey. I know of no doctor in the past, or present time, of whom I was so truly glad to learn, of his life and character, as that of Dr. Mussey.

Within the last few months, through the kindness of Dr. Parsons of Portsmouth, N. H., I learned of the life of Dr. Mussey, before his coming to Ohio, as given before the New Hampshire Medical Society, at its one hundredth anniversary, and now I have the excellent article, by Dr. Hamilton, with a good picture of Dr. Mussey; his autograph I have had for a long time, as found attached to my father's diploma, given to him at Dartmouth Medical College in 1835—Dr. Mussey was lecturing on anatomy, surgery and obstetrics at that time.

My father, Dr. Cyrus Blaisdell, who died when I was some six years of age, was a favorite student of Dr. Mussey, it would seem, who after receiving a thorough training in anatomy and surgery under Dr. Moses Sweat of Maine graduated at Dartmouth, remaining after that six months as a private student with Dr. Mussey, where he had the benefit of his teaching and friendship. Dr. Sweat at that time was one, if not the best, of the country doctors in the State of Maine, he having had the assistance for years of Dr. Alexander Ramsey of Edinburgh, Scotland, he having lectured in that city before coming to America. Sweat when an old man, past eighty, said Dr. Blaisdell was the best read student that he had ever had under his care.

In looking over files of letters, in the old leather trunk that did service for two generations of students, at Dartmouth and Brunswick colleges, I find a number of letters, written by Dr. Mussey, one also by Dr. Alcot of Boston, to my father saying that Dr. Mussey had referred him to Dr. Blaisdell for help, on a book he was then preparing on Vegetable Diet.

The letters show him, Dr. Mussey, to be so much like the character given him by Dr. Hamilton, that I can plainly see how true the article is, as written by Dr. Hamilton; the letters

show that he did not regard the practice of medicine the only duties of a doctor, but that there were moral and social duties that were required at his hands, and the letters show how ready he was to give credit for moral and religious worth, as found in his students, and to help them, as he best could by showing their good points to advantage, by calling the attention of those, who were able to judge best in these matters; he must have been a big hearted man, one whose conflict with life had not made him hard or selfish. I find among other papers, a part of a temperance lecture, which must have been delivered shortly after my father had left the medical school; it was about the time Neil Dow was beginning his temperance work in Maine, some sixty years ago. The lecture met with much favor, it would appear, in the rather scholarly town in which he had located. I was surprised, to see how fearless as a young doctor, he handled his subject, neither having fear of foe, or quoting favors, showing plainly the action of alcohol in its various forms on the human system, and its moral and political influence throughout the broad land of ours. It appears to me, although some sixty years have gone by, that he handled his subject with as much skill and force as those of this later day, and now I can see how fully he was prepared to battle with that great evil of all times, intemperance, by having the example and teaching of that great and religious man, Dr. Mussey, who labored so faithfully for the moral good of his students.

How much pleasure it no doubt would have afforded Dr. Mussey, could he have then known in life, that in years long after, when life's work was over, he should be so well remembered, as he is in the article given us by Dr. Hamilton, and it does seem good in these times of rush and push, on and on, when one is forgotten ere he is hardly gone, that one yet finds some, like Dr. Hamilton, who appreciate moral worth, and are willing to bring it before those who are about coming on to the field of action in life, and to whom it will be an incentive to do right, because it is right, without fear or favor.

Very truly,

IRVING C. BLAISDELL, M.D.

It may be One of Those Letters.

GROVELAND, MASS., April 29, 1896.

To the Editor:—I am surprised to find that the medical journal which professes to lead medical journalism in this country, has space to print this attempted slur at the AMERICAN MEDICAL ASSOCIATION. The question—"The AMERICAN MEDICAL ASSOCIATION, what is it?" reminds me of an experience we had in the good old city of Boston not long ago.

Among the heroes of the Civil War was Col. Robert G. Shaw, whose gallantry men who wore the blue or the gray were equally glad to honor. As a slight tribute to his worth, it was proposed to erect a statue to his memory, and the matter came up for discussion in the council. One of the rulers of modern Boston, an Irishman who, I presume, had not been very long in this country, arose and asked, "Who was Col. Robt. G. Shaw, anyhow?"

The AMERICAN MEDICAL ASSOCIATION, for some reason or other which I am not able to understand, has some very bitter enemies, and more the pity of it, among the medical profession of this country.

I greatly regret that I can not be present at the meeting in Atlanta. It would do me good just to look at the manly men, members of the medical profession from all sections of this great and growing country, who expend large sums of money, often denying themselves, to do honor to the ASSOCIATION. So in answer to the question, "The AMERICAN MEDICAL ASSOCIATION, what is it?" I would say for the benefit of those who do not know, that it is an association composed of medical gentlemen from every State and Territory of this Union, who meet for the benefit of medical science to learn how to control disease and be of service to their fellow men. The ASSOCIATION publishes

a journal which in every respect is a credit to American medical genius.

I remember that the editor of the *Record* once said to me that when he had a subject to discuss he would write a letter purporting to come from a hayseed in some way-back town, and then answer it. Perhaps this may be one of those letters.

With best wishes for the success of the AMERICAN MEDICAL ASSOCIATION and of its meeting in Atlanta, together with my sincere appreciation for the able manner in which our JOURNAL is managed and edited, I am, Very sincerely yours,

W. T. PARKER, M.D.

Recurrent Scarletina.

MONTPELIER, OHIO, April 29, 1896.

To the Editor:—The following is to me a unique case, and may prove so to many of the brethren. I therefore desire to report it. Was called some time in January of this year to see a boy 10 years of age, suffering from well defined scarlatina. It ran the usual course, desquamation being complete even to the finger and toe nails. Four weeks ago, being the last of March, saw him again, having scarlatina: case pursued usual course, desquamation as before. He had been up and around about a week, when a third attack seized him: desquamation is at the present time going on. The exfoliation is so complete and followed so soon after the second attack, that patient is rendered extremely sensitive, in some situations blood oozing through the skin.

Five years ago, according to the parents, the boy had an attack of scarlatina and was treated by a competent physician. This makes four attacks in the same person, the last three happening within four months. I should like to know if any of the brethren have similar experiences, or whether this case is particularly unique? Truly yours,

H. M. BYALL, M.D.

To the Members of the Medical Profession.

PHILADELPHIA, PA., May 1, 1896.

My two collective reports which are already published on Ice-cold Applications in Acute Pneumonia give a record of one hundred and ninety-five cases so treated, with seven deaths, or a mortality rate of 3.58 percent.

Being desirous of making as full a report as possible on this subject, I take the liberty of asking those who have tested this measure to kindly give me the result of their experience. Full credit will be given to each correspondent in the report which I hope to publish. Blanks for the report of cases will be furnished by me on application. THOMAS J. MAYS, M.D.

1829 Spruce Street.

Southern Baptist Excursion.

BROOKLYN, N. Y., April 29, 1896.

To the Editor:—I cut the enclosed slip from the *Watchman*: The Southern Baptist Excursion: The Seaboard Air Line will run a personally conducted excursion to Chattanooga, Tenn., for the Southern Baptist Convention to be held in that city May 8 to 14 inclusive. Solid vestibuled train. One fare for the round trip. For particulars address J. Strang, New England Passenger Agent, Seaboard Air Line, 306 Washington Street, Boston.

One would think that the railroad corporations could be, and would wish to be, as liberal to those who care for the physical as for the spiritual welfare of their patrons. I know the JOURNAL is laboring in that direction. This requires no personal reply. Yours truly,

N. W. LEIGHTON, M.D.

SOCIETY NEWS.

Medico-Legal Society of New York. At a meeting of this society held at the Marlborough Hotel, April 15, among the scientific papers read, was one on the Röntgen rays in medico legal surgery, by J. M. Bleyer, M.D.

The "Western Association of Eye, Ear, Throat and Nose Surgeons" was organized at Kansas City, Mo., April 10. Seventy-five surgeons were in attendance. Adolf Alt, of St. Louis, was elected president.

The Tennessee State Medical Society held its sixty-third annual meeting at Chattanooga, Tenn., April 14. President, G. C. Savage, M.D., Nashville. The delegates were welcomed on behalf of the citizens by Mayor Ochs, and by Dr. G. A. Baxter on behalf of the local members of the profession. Among the members who have been longest connected with the association appear the names of Dr. J. B. Lindsley, Nashville, who entered the society in 1845; Dr. T. Briggs and Dr. Thomas J. Maddin, in 1853.

Mississippi State Medical Association.—The twenty-ninth annual meeting of this association convened at Vicksburg, Miss., April 16; President, Dr. R. H. Haralson, of Forrest City. Hon. Murray F. Smith welcomed the association to the city. Dr. T. P. Lockwood, of Crystal Springs, in his response advocated the establishment of a medical department of the University of Mississippi and the erection of a college and hospital. President Haralson and others urged the necessity of such a department.

The Iowa State Medical Society, Dr. David S. Fairchild, of Clinton, President, held its forty-ninth annual session at Des Moines, Iowa, April 16, 17 and 18. The address of welcome was delivered by Hon. Sidney A. Foster, of Des Moines, to which J. M. Emmert, M.D., responded. Many papers on medicine, surgery, hygiene, etc., were presented. The session was well attended and much interest evinced. The officers elected for the ensuing year were: President, E. L. Baker, M.D., Indianola; Secretary, J. W. Cockenower, M.D., Des Moines; Assistant Secretary, C. C. Tuttle, M.D.; Treasurer, Geo. B. Skinner, M.D., Cedar Rapids. The next meeting of the society will be held at Marshalltown, Iowa.

District of Columbia Medical Association.—At the regular meeting of the Medical Association of the District of Columbia held April 7, the following officers for the ensuing year were elected: President, Dr. W. P. Carr; Vice-Presidents, Drs. Hawkes and Scott; Secretary, Dr. J. R. Wellington; Treasurer, Dr. H. M. Deetle; Counselors, Drs. Cook, McLain, Ober, Holden, Acker, Kober, T. R. Stone, Yarnell and D. O. Leech; Censors, Drs. Woodward, Ruffin and Mayfield; delegates to the meeting of the AMERICAN MEDICAL ASSOCIATION to be held in Atlanta, Ga., May 5, 6, 7, and 8, 1896, Drs. J. T. Johnson, Kleinschmidt, Belt, Sothoron, Heiberger, Franzoni, L. Eliot Rich, Woodward, Nordhoff, I. S. Stone, S. Muncaster, Magruder, Acker, Kober, Bowen, Nash, Wellington, C. G. Stone, Cook, Fry, Morgan, W. W. Johnston, Van Rensselaer, Bussey, F. Leech, J. F. Thompson, S. S. Adams, Lincoln, Hunt, McLaughlin, J. D. Morgan, Mayfield, Peter, Suter and Carr.

Medical Association of the District of Columbia.—At a special meeting of the Association held on the 23d ult. the following was adopted:

WHEREAS, There is now pending in both Houses of the Congress of the United States, a bill entitled "A bill for the further prevention of cruelty to animals," which, if enacted into a law will prohibit vivisection or animal experimentation in the District of Columbia, and effectively close the biological laboratories connected with the Surgeon-General's Department of the United States Army, Bureau of Animal Industry of the Department of Agriculture, and Marine-Hospital Service, and prohibit all illustrative experimentation on living animals in the medical colleges of this District; and

WHEREAS, The proposed legislation is being urged with unremitting zeal and persistence by the humane societies and their coadjutors throughout the country, by personal solicitations of Senators and Representatives, by letters and petitions setting forth charges of cruel and atrocious tortures upon dumb animals committed by investigators and experimenters in medical and biologic research, and by misrepresentation and perversion of facts established by biologic and experimental

investigation, to which the science of medicine owes its present stage of advanced progress and wider scope of beneficence; and

WHEREAS, It is not known to this association, or to any member thereof, that such alleged abuses and cruelties are being, or have been, perpetrated in any of the biologic or medical college laboratories in this District, and it is assured by those in charge of such laboratories that such charges are without foundation; and

WHEREAS, The medical profession throughout the country does not seem to realize the significance and importance of such proposed legislation, which, in its direct operation, will be limited to the District of Columbia, but in its indirect effects will add impetus and force to this crusade against the scientific progress of medicine in general, this association appeals to the AMERICAN MEDICAL ASSOCIATION for such expression of the consensus of medical opinion on the subject as it may in its wisdom see fit to promulgate; therefore, be it

Resolved, That the delegates of this association to the meeting of the AMERICAN MEDICAL ASSOCIATION, at Atlanta, Ga., be instructed to present this memorial to that ASSOCIATION and ask a prompt and favorable consideration; secondly,

Resolved, That a copy of this memorial be sent to the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, with the request that it be published in the next ensuing issue of that JOURNAL.

W. P. CARR, M.D., J. R. WELLINGTON, M.D.
President. Secretary.

The American Orthopedic Association.—Preliminary program of the tenth annual meeting to be held at Buffalo, May 19, 29 and 31, 1896:

The President's Address. Royal Whitman, New York.

Some practical points in the treatment of Lateral Curvature of the Spine. A. B. Judson, New York.

Some Etiological factors in Lateral Curvature of the Spine. E. G. Brackett, Boston.

Cases illustrating the absurdity of treating ordinary Lateral Curvature (Scoliosis), by Spinal Supports. Bernard Roth, F.R.C.S., London.

The rationale of Gymnastic Exercise and Pressure Correction in the treatment of Scoliosis. L. A. Weigel, Rochester.

The rapid cure of Rotary Lateral Curvature of the Spine and other postural deformities by means of thorough development, and corrective exercises with heavy weights. With a demonstration of the method. (By invitation). Jacob Teschner, New York.

A simple and efficient brace for Lateral Curvature. S. L. McCurdy, Pittsburg.

Congenital Misplacement of the Femur anteriorly. DeForest Willard, Philadelphia.

Further remarks on Congenital Dislocation of the Hip. Bernard E. Brodhurst, F.R.C.S., London.

Report of a case of double Congenital Dislocation of the Hip, treated by the Lorenz method of operation. Reginald F. Sayre, New York.

The Cure of Congenital Dislocation of the Hip by means of the "functional weighing" method, without open operation. Adolf Lorenz, Vienna.

Spontaneous Dislocation of the Hip. William J. Taylor, Philadelphia.

The treatment of Club-foot: (a) When to commence treatment and how. (b) The indications for mechanical treatment. (c) The limitations of mechanical treatment. (d) The indications for operative treatment. (e) Results in 343 operations performed by the writer. A. M. Phelps, New York.

Investigations on Flat-foot. E. H. Bradford, Boston.

Mechanical Support for Flat-foot. John C. Schapps, Brooklyn.

The Anterior Transverse Arch of the Foot. Joel E. Goldthwait, Boston.

Injuries of the Tarsus and the Ankle Joint. J. D. Griffith, Kansas City.

Subtendinous Exostosis. E. G. Brackett, Boston.

The mechanical treatment of Ingrown Toe Nail. Henry Ling Taylor, New York.

The operative treatment of Paralytic Deformities of the Foot with practical reference to Arthrodesis. V. P. Gibney, New York.

Some mechanical problems in the treatment of Pott's disease. John C. Schapps, Brooklyn.

The operative treatment of threatening abscesses in the high dorsal region. E. H. Bradford, Boston.

The treatment of Pott's Paraplegia with a report of two cases. LeRoy W. Hubbard, New York.

Osteomyelitis of the Spine. T. Halsted Myers, New York.

Suppuration in Joint and Spinal disease and its relation to

Tubercular Meningitis. An Analytic study. Samuel Ketch, New York.

A study of the action of Iodoform Glycerin in tubercular osteomyelitis. Harry M. Sherman, San Francisco.

Joint disease in Infancy. Augustus Thorndyke, Boston.

The use of Dry Heat of high temperature in the treatment of Chronic Joint Affections. William E. Wirt, Cleveland.

A theory of the Ultimate Etiology of Deformity and its practical application. Royal Whitman, New York.

The probable cause of the limp in the first and second stage of Hip Joint Disease. Harry M. Sherman, San Francisco.

Femoral Osteotomy for correction of hip deformity in adults, with a report of cases. (By invitation). A. R. Shands, Washington.

A report of cases of Osteosarcoma of the Hip. Arthur J. Gillette, St. Paul.

Division of the hamstring tendons by the open method for correcting malposition and securing rest in Tubercular Disease of the knee. Bernard Bartow, Buffalo.

Tuberculosis of the wrist and carpus. James E. Moore, Minneapolis.

Symptoms and treatment of Slight Knock Knee in children. Robert W. Lovett, Boston.

Two cases of Dislocation of the Patella treated by operation. Joel E. Goldthwait, Boston.

Some notes on Spastic Paralysis in children. F. S. Coolidge, Chicago.

Some recent modifications in the treatment of Congenital Wry Neck. William Adams, F.R.C.S., London.

Contracted Fingers. Arthur J. Gillette, St. Paul.

Congenital Club Hand, the report of a case treated by operation. (By invitation). C. Thomson, Scranton.

Rare cases from Practice. A. J. Steele, St. Louis.

A report of some cases of unusual Congenital Deformities. John Ridlon, Chicago.

Congenital defects of the long bones, a report of cases and operations. B. E. McKenzie, Toronto.

Deformities of the Humerus due to Rickets. Augustus Thorndyke, Boston.

A report of a Family of Anomalies. S. L. McCurdy, Pittsburg.

Readers will please prepare abstracts of their papers, in order that the proceedings of the meeting may be satisfactorily reported.

JOHN RIDLON, M.D., Secretary,
103 State Street, Chicago.

ROYAL WHITMAN, M.D., President,
126 West 59th Street, New York.

PUBLIC HEALTH.

The New York State Board of Health bulletin for month of February gives total deaths in the State 9,825 as against 8,789 as average for series of years for same month.

The Registration of the physicians of Hamilton County (Ohio) showed 790 who desired to practice in Cincinnati. The arrangement made by Dr. Chas. A. L. Reed, whereby registration was made at his office, met with hearty approval and merited the thanks of the profession, for by his action they were saved the trouble and expense of either sending their diplomas and affidavits to Columbus or making the trip in person. Dr. Frank Winders, the secretary of the Board, spent the three days in Cincinnati, and Dr. N. R. Coleman came down for two days to give any desired information. He made important rulings in several questions, among which were, as to whether the internes of hospitals, and physicians from outside the State who held college clinics here, were compelled to register. Both these he decided in the affirmative.

Ignorance of Adulteration no Defense.—In the enactment of the Ohio statute of 1884, "to provide against the adulteration of food and drugs," the supreme court of Ohio says, in the case of State v. Kelly, Feb. 25, 1896, that it was the evident purpose of the general assembly to protect the public against the harmful consequences of the sales of adulterated foods and drugs, and, to the end that its purpose might not be defeated, to require the seller, at his peril, to know that the article which he offers for sale is not adulterated, or to demand of those from whom he purchases indemnity against the penalties that may

be imposed upon him because of their concealment of the adulteration of the articles. In a prosecution under this law, it is not a defense that the accused was ignorant of the adulteration of the article which he sold or offered for sale.

The Water-cooler on Railway Cars and Typhoid Fever. According to the *Insurance Monitor*, the intimate relation of typhoid fever to the water tank of the railway car, was strikingly exemplified a few weeks since by the experience of the medical director of one of our principal life companies. His family had been sojourning for the summer at a popular resort. Very shortly after returning to his home, three children were simultaneously taken down with the disease. No other case had occurred among the numerous guests. The origin was investigated, and it was found that the water tanks on the train returning had been filled from a village well on the way. The fever was raging there among those who were using the water. The trifling quantity drank during the few hours of transit was sufficient to implant the germs of the disease.

Again the Oyster.—Our English cousins are very tenacious of an idea once lodged in their sensoria. They have convicted the oyster of various malefic powers, as in the causation of Asiatic cholera, typhoid fever, etc. And now whenever death follows the ingestion of the bivalve the odds are that it is in some way connected with the fatal result. Thus when Col. John T. North, the famous "Nitrate King," died suddenly a few days since, while presiding at a meeting of the nitrate companies of which he was the head, and it was learned that shortly before the meeting he had eaten a dozen oysters, what more natural than to conclude—*post hoc, propter hoc*—that the oysters had caused the death? We are seriously informed by cable that "the shells have been retained for examination." Those who have seen Col. North within the last few years will have no difficulty in believing that his sudden death was due to fatty heart rather than to his oyster luncheon *per se*, and no true American will be deterred by this untoward incident from indulging, in due season, in the *O. virginica* whatever he may think of the *O. edulis*.

Healthfulness of Buffalo.—The death rates of American cities are among the vexations of the sanitarian and the vital statistician. The total deaths may be known and recorded with substantial accuracy; but as to the population of any given city—well, one man's guess is as good as another's. In New York, for example, up to April 27, 1895, the population was "estimated" at 2,013,723, and the death rate for the week ended on that date—the total deaths reported being 885—was figured at 22.93 per annum in the weekly report of the New York Health Department. In the report for the following week this rate shot up to 25.07, while the deaths reported were 890, or only five more than for the previous week. The explanation is found in a footnote on the first page of the May 4 report: "Police census, April 15, 1895, 1,819,866"—a shrinkage of more than 7 per cent. in the "estimated" population. Similarly as to Chicago, which has been boasting of its "phenomenal healthfulness." Its alleged death rate of 15.24 per 1,000 in 1894, now turns out to be based on a population "padded" 5 per cent. by the school census people of that year; and its death rate of 15.11 for last year is based on a 2.05 per cent. increase over the "padded" school census figures of the previous year. Dr. Gram, Registrar of vital Statistics of the Buffalo Health Department, has chosen a better way. While he does not hesitate to figure out death rates on population more or less "estimated," he also gives a table of deaths reported year by year, showing an astonishing reduction in the past five years, as witness: 1891, deaths 6,001, rate 23.48; 1892, 5,697, 19.98; 1893, 5,711, 19.03; 1894, 5,280, 16.76; 1895, 4,681, 13.95. Assuming that the population has been stationary during this period, here is a falling off of nearly 22 per cent. in the actual number of deaths in five years. Dr. Gram says: "Undoubt-

edly the cause of this great reduction in the number of deaths is mainly due to the decrease in communicable diseases, including consumption, the percentage of deaths in these having decreased from 7.42 in 1891 to 4.04 in 1895." He somewhat ingenuously adds: "This fact [the decrease in the actual number of deaths] has undoubtedly manifested itself to most practitioners when they made a comparison between their present and past book accounts, and no small number have made investigations as to the cause." Verily, the physician who relies for his income on the demand for his services in the treatment and not the prevention of disease, has fallen on evil times. *Sanitas sanitatem, omnia sanitas!*

An Object Lesson for Antivaccinists.—The city of Gloucester, in the west of England, has for years been the center and headquarters of the antivaccination movement in that country. The authorities charged with securing vaccination have for nine years, or more, persistently and successfully resisted all efforts to compel them to do their duty. Naturally and logically, smallpox is now reaping its harvest. During the first three and a half months of the present year 1,300 cases had been notified and at last accounts fresh cases were occurring daily. The population of Gloucester is 42,000, so that during the period mentioned one out of every thirty-two or thirty-three of the inhabitants had already been attacked. In common with the general experience of all smallpox epidemics, as far as records of cases that have already occurred are available, they show amongst other things, that the heaviest percentage of mortality has been among the unvaccinated, and that where unvaccinated patients have not actually died they have suffered severely, and in a great number of cases will be permanently disfigured or blind. The vaccinated infants have escaped, whilst the unvaccinated ones have suffered heavily, and where adults who have been vaccinated, often inefficiently, in their infancy, have been attacked, the severity of the disease has been mitigated, and the attack has frequently been so mild as to be scarcely perceptible.

The *British Medical Journal*, April 25, says: "The epidemic has had a marvelous effect in promoting vaccination throughout the country, and has to a great extent counteracted during the last few weeks the mischief caused by the delay which has been allowed to occur in the issue of the report of the Royal Commission on Vaccination. The guardians of the Gloucester Union, after refusing for nine years to enforce the law, have at last, but too late, repented of their folly, and have issued notices urging parents and others to obtain the prompt vaccination of their children, as 'the only means of promptly stamping out the present epidemic of smallpox.' The result of this change of front, aided by the vigorous action of the Town Council, has been that within a few weeks upward of 25,000 vaccinations and revaccinations have been performed in a population of about 42,000. It is to be hoped that this scramble for vaccination during a panic will not result in the performance of much unprotective vaccination. At the same time, one after another of the apathetic and recalcitrant boards of guardians have resolved once more to enforce the vaccination acts, and to wait no longer for the long delayed report of the Royal Commission."

Health Reports. The following health reports have been received in the office of the Supervising Surgeon-General Marine-Hospital Service:

SMALLPOX—UNITED STATES.

Michigan: Bay City, Detroit, Ionia and Marine City, April 11 to 18, smallpox reported.
Kansas: Leavenworth, March 28 to April 4, 2 cases.
Louisiana: New Orleans, April 11 to 18, 37 cases, 28 deaths.
Florida: Pensacola, April 22, 1 case.

SMALLPOX—FOREIGN.

Bombay, March 17 to 24, 32 deaths.
Buda Pesth, March 25 to April 1, 2 cases.
Cairo, March 11 to 18, 1 death.

Calcutta, March 7 to 14, 6 deaths.
 Callao, March 8 to 15, 5 deaths.
 Cardiff, April 4 to 11, 2 cases.
 Cienfuego, April 5, to 12, 2 deaths.
 Dublin, April 4 to 11, 1 case.
 Guayaquil, April 3 to 10, 4 deaths.
 Hong Kong, March 1 to 14, 2 cases, 1 death.
 Leeds, April 4 to 11, 1 case.
 Madrid, April 1 to 7, 13 deaths.
 Montevideo, March 14 to 21, 1 case, 1 death.
 Odessa, March 28 to April 4, 11 cases.
 Prague, March 28 to April 4, 5 cases.
 Rio de Janeiro, March 14 to 28, 18 cases, 9 deaths.
 St. Petersburg, March 21 to 28, 13 cases, 2 deaths.
 Swansea, April 4 to 11, 5 cases, 1 death.
 Trieste, March 28 to April 4, 1 case.
 Santiago de Cuba, March 30 to April 4, 1 death.
 Southampton, March 28 to April 4, 3 cases.

CHOLERA.

Bombay, March 17 to 24, 3 deaths.
 Calcutta, March 7 to 14, 140 deaths.

YELLOW FEVER.

Rio de Janeiro, March 14 to 21, 638 cases, 459 deaths.
 Sagua la Grande, April 4 to 11, 3 cases.
 Santiago de Cuba, March 30 to April 4, 5 deaths.

ADDITIONAL REPORT RECEIVED MAY 1.

SMALLPOX—UNITED STATES.

Louisiana: New Orleans, April 18 to 25, 69 cases, 20 deaths;
 Shreveport, April 18 to 25, 12 cases in pest house.
 Michigan: Bay City, April 18 to 25, smallpox reported;
 Ionia, April 18 to 25, smallpox reported.
 Ohio: Dayton, April 16 to 30, 2 cases.

SMALLPOX—FOREIGN.

Acapulco, April 11 to 18, 2 cases, 2 deaths.
 Birmingham, April 11 to 18, 4 cases.
 Bombay, March 24 to 31, 47 deaths.
 Calcutta, March 14 to 21, 3 deaths.
 Cardiff, April 11 to 18, 1 case.
 Genoa, April 11 to 18, 1 case.
 Glasgow, April 4 to 11, 1 case.
 Guayaquil, April 10 to 17, 5 deaths.
 Leeds, April 11 to 18, 1 death.
 London, Eng., April 4 to 11, 21 cases.
 Madrid, April 7 to 14, 11 deaths.
 Moscow, April 21 to 28, 1 case.
 Naples, March 31 to April 13, 25 cases, 10 deaths.
 Odessa, April 4 to 11, 13 cases, 4 deaths.
 Paris, April 4 to 11, 1 death.
 Prague, April 4 to 11, 3 cases.
 St. Petersburg, April 4 to 11, 15 cases, 6 deaths.
 Swansea, April 11 to 18, 11 cases.
 Tuxpan, April 11 to 18, 8 deaths.
 Warsaw, April 4 to 11, 3 deaths.
 Alexandria, March 26 to April 1, 1 death.
 Cairo, March 26 to April 1, 3 deaths.

CHOLERA—FOREIGN.

Alexandria, March 18 to 25, 1 death.
 Bombay, March 24 to 31, 8 deaths.
 Calcutta, March 14 to 21, 173 deaths.

BUBONIC PLAGUE.

Hong Kong, March 14 to 28, 83 deaths.

MISCELLANY.

The Iowa Public Health Association will meet at Davenport, Iowa, May 19 and 20.

A Boston merchant, who declines to have his name published, is reported to have given \$100,000 to Harvard University to establish a department of comparative pathology.

Alabama Exempts Dentists from Jury Duty.—A law was passed in Alabama in 1895 providing that all practicing dentists in the State shall be exempt from jury duty.

Burden of Proof as to Insanity in Georgia.—Where insanity at the time of the commission by an adult of an indictable act is set up as a defense, the supreme court of Georgia holds, in *Keener v. State*, decided Dec. 13, 1895, the burden of proving the alleged insanity by a preponderance of the evidence rests upon the accused.

College Commencements.—Commencement exercises of the Maryland University School of Medicine, Baltimore, Md., were held April 16 with sixty-one graduates. Gross Medical College, Denver, Colo., graduated twenty-six new M.D.'s April 9.

Recognition of "Rush."—At a quarterly meeting of the council of the Royal College of Surgeons of England, held April 9, the President, Mr. Christopher Heath, being in the chair, it was resolved that Rush Medical College of Chicago should be added to the list of foreign institutions recognized by the Examining Board for the complete course of study required by the regulations.

Physicians Can Sell Drugs in Alabama.—A law was passed in Alabama in 1895 that all regularly graduated physicians, who have complied with the laws of the State, as they now are, entitling them to practice medicine, are also authorized to fill prescriptions of other physicians, compound medicines and poisons, and sell the same, and to carry on the business of a druggist, or a drug store, or apothecary shop.

Low Patent For Holding Artificial Teeth Invalid.—Feb. 14, 1896, the United States Circuit Court, E. D., New York, held in the case of *International Tooth-Crown Co. v. Bennett*, that the patent, No. 238,940, granted to James E. Low, dated March 15, 1881, for a method of permanently fixing artificial teeth to the mouth by bands around the natural teeth, in dentistry, is void, on account of prior knowledge and use.

Successful Serum Treatment of Leprosy.—*El Monitor Médico*, of Lima, March 1, reports the results of fifteen cases of leprosy treated with serum by Carrasquilla of Bogota. The disease was certainly arrested by the very first dose, and all the local symptoms gradually subsided; sensibility, appetite and cheerfulness returned, and Carrasquilla considers them practically cured.

Coal Mining Not Conducive to Malignant Disease.—According to the *British Medical Journal*, Mr. T. Law Webb, surgeon of two coal fields in Shropshire, says that books of the district registrar show that of all those whose deaths are registered as due to malignant disease during the past thirty years, only two are described as coal miners. This immunity is thought to be owing to the fact that they work underground, and do not drink casual water.

Tracheotomy Tubes for Race-Horses.—According to the *Boston Medical and Surgical Journal*, the prevention of "roaring" in race-horses otherwise valuable, has been a desideratum of horse breeders for many years. It has been accomplished by the simple surgical operation of tracheotomy. The value of this procedure is attested by the fact that in the Selling Steeplechase at the second January meeting at Manchester, England, the horses that finished first, second and fourth, wore silver tubes in their windpipes.

A National Conference of sanitarians, including representatives from all the State boards of health, will convene in Chicago June 10, and remain in session for at least three days. C. O. Probst, M.D., Secretary of the National Board, and John W. Scott, M.D., Secretary of the Illinois State Board of Health, with Commissioner Kerr and Dr. F. W. Reilly of the Chicago health department, have completed plans for the convention. The visiting delegates will be welcomed by Governor Altgeld on behalf of the State and by Mayor Swift for the city. Every State board has been asked to submit propositions for discussion, with the result that all topics of interest in sanitary science will be presented. The program includes excursions to, and inspection of the drainage canal, the cribs and intakes of the city water supply and the stockyards.

Heraldic Devices for Medical Men.—According to the *Brooklyn Medical Journal*, the tribute of a banquet has lately been attended in honor of the veteran galvano-cauterist, Dr. John Byrne. Dr. Shoop, responding to a toast, said he was re-

minded of the time when the late Sir James S. Simpson, the originator of chloroform anesthesia in childbirth, had lately come into his title, and a brand new coach was nearly ready for delivery to the new knight. He was at a loss for a suitable coat-of-arms and legend to put upon the carriage, and in his dilemma he consulted a friend who was somewhat of a wag. "Why, doctor," he replied, "paint on your carriage a new-born babe, and under it place the motto: 'Does your mother know you are out?'"

"Dr. Byrne, if you are in quest of a coat-of-arms paint the form of a lovely woman and inscribe the motto above her: 'Saved as by fire.'"

A Non-committal Certificate of Death.—Dr. Nathaniel K. Whittemore of Elk River, Minn., is regarded by the *General Practitioner* as a kind of local celebrity on account of his certificate of death tendered by him in a will contest case. The certificant was evidently willing to certify to the fact of death, but the cause of death was another matter. The certificate reads as follows: "This is to certify that Sarah Langen, supposed to be single, died on Feb. 8, 1895. I have had no memorandum stating just the cause of death, and I have had more to think about in caring for the living than thinking about the dead. I am quite certain that she is dead, and have certified to that fact at least once before. She was a patient of mine, and that ought to at least give me authority to know whereof I speak: and, possibly, that ought to be sufficient guarantee that she is dead."

Arsenical Fly-paper Used for Suicidal Purpose.—The *Medical Press and Circular* congratulates the Pharmaceutical Society of Great Britain for its energy in prosecuting unlicensed vendors of poisonous preparations, and makes note of the new departure taken in the direction of bringing actions against grocers who deal in poisonous fly-papers. A case of this description was recently heard in respect to the sale of twenty-five fly-papers, the composition of which on analysis showed an average of *eight grains of arsenic in each*. The governmental chemist for the prosecution agreed with the analysis that had been made, and he also pointed out that two grains of arsenic was a fatal dose for an adult. The only defense made was that wallpapers, posters, and various fabrics contained arsenic. But the judge declined to admit this evidence, and gave judgment for the plaintiffs, namely, £5 and costs. In regard to poisonous fly-papers, the use to which they are put for suicidal purposes has been repeatedly brought under public notice, and it is therefore highly essential that their sale should be restricted, at all events to those tradesmen whose business it is to deal in drugs.

An Itinerant Physician not Entitled to Practice. The supreme court of Rhode Island, Feb. 11, 1896, affirmed the decision, in the case of *Evans v. State Board of Health*, that here was a party who was to be regarded as an itinerant doctor, within the meaning of the statute relating to the practice of medicine in that State, which provides that "nothing in this chapter shall be so construed as to authorize any itinerant doctor to register or to practice medicine in any part of this State." He was a domiciled resident of Boston, Mass., and a practicing physician, making a specialty of the treatment of catarrh. His main or regular office was in Boston, and for years past, except when absent from the country or prevented by illness, he had visited Providence in the practice of his specialty on stated days each month. He had no office in Providence except the rooms he had taken in the hotels at which he stopped. He notified his patients of his visits by advertisements in a Providence newspaper, and had met them in his rooms at the hotels at the times mentioned in the advertisements. He had also during this ten years, for greater or less periods, been in the habit of visiting, in the practice of his specialty, Worcester, Springfield, New Bedford and Lowell, Mass., in the same manner as he had visited Providence. On these facts, the court holds that the decision of the State Board of Health, as above, was correct.

Not an Expert on Determining Facts.—A physician was called as an expert witness in a murder case where the defense was insanity. He testified that he had made an examination of the defendant before the trial, with reference to his life with his wife, the beginning of his domestic trouble, their continuance, a trip West and return, his attempt to get into business, his letters that he wrote to different people, his attempt at reconciliation, etc. He was then asked to state his conclusion as to the defendant's sanity or insanity at the time of the tragedy. Feb. 25, 1896, the court of appeals of New York holds *People v. Strait*, that the trial court was right in refusing to allow the question to be answered. It says that the witness was an expert on the diseases of the mind, but he was not an expert on determining the facts, where such facts had to be obtained from the statements of others. It then explains that it was essential that the jury should be informed as to the facts upon which the expert based his conclusions in order to determine whether they were well founded. If the facts were not disclosed his conclusions could not be controverted. He might have been deceived by a false statement prepared for the occasion, and for the purpose of making him a valuable witness upon the trial. This, with regard to information derived by the physician from statements made by others not under oath. But a physician may acquire facts from his own observation. There is much, continues the court, in the actions, conduct and appearance of a person that aids the physician in forming a conclusion as to the difficulty. The facts so acquired the physician may himself give in evidence, at least so far as they can be described.

Acquittal of a Physician Unjustly Accused.—A practitioner of Brooklyn, Dr. Carl F. Gessler, had a narrow escape from a trap prepared for him by an admittedly guilty midwife, abortionist, in conjunction with her servant. The midwife "turned State's evidence" in the expectation of having sentence ameliorated under plea of guilty. The case was one of fatal results after alleged criminal abortion, and the practitioner testified that he had no suspicion of criminality until, after the death of the patient, the midwife ran away. The closing scenes of the trial were replete with interest, because of the number of medical experts who testified in the doctor's defense. Among them were Dr. George R. Fowler, Dr. Francis H. Stewart, Dr. George H. Jeffrey, Dr. August H. Ritter, Dr. Charles W. Brandenburg and others. All were called as experts in different lines, and in answer to the long hypothetical questions said that the patient's death was in their opinion due to exhaustion caused by incessant vomiting; that her case was hopeless from the time that Dr. Gessler was called in, and that his treatment of her was absolutely proper. Each said that any operation performed with criminal intent, must have been prior to the doctor's first visit. The result was an acquittal. The guilty midwife was discharged by the judge, after a severe rebuke. The judge stated that if the law permitted he would with great satisfaction have imposed a sentence of murder, were it not for the fact that the effort of the district attorney to fasten the crime upon the physician made it possible for the midwife to go free.

Did not Show Required Qualification.—The second clause of chapter 1353, section 3, of Public Laws of Rhode Island, of May 16, 1895, the supreme court of that State construes as being intended to apply to physicians who, not possessing a diploma from a reputable and legally chartered medical college, indorsed as such by the State Board of Health, as required by the first clause of the section, had been in practice a sufficient length of time prior to Jan. 1, 1895, and with sufficient success, to have acquired an honorable reputation in the community as practitioners. Satisfactory evidence of possessing this qualification, so as to entitle him to a certificate to practice medicine, the court holds was not furnished, in the case of *Paquin*

v. State Board of Health, decided Feb. 11, 1896, where the testimony showed that the applicant was for several years prior to 1889 engaged in the dry goods and boot and shoe business; that in 1889 he took up by himself the study of medicine, and later in that year began to practice, chiefly, if not wholly, among the French residents of the town; that from the latter part of 1889 he gave his attention exclusively to the practice of medicine, leaving the dry goods and boot and shoe business to be managed by clerks; and that he continued his practice up to Jan. 1, 1892, some of his patients being satisfied with his services, and some not. And, on the ground that there was no evidence that on Jan. 1, 1892, he had come to be regarded by the community in which he practiced as a skillful and successful practitioner, and therefore had acquired the honorable reputation as a physician necessary to qualify him to practice contemplated by the statute, as above stated, the court confirms the decision of the State Board of Health denying a certificate to him.

Dislocation of the Spine and Consequent Hyperpyrexia.—The following case of the above-named complication is given by Dr. C. Lambette in *La Presse Médicale Belge*: A female, aged 40 years, was brought to the hospital at Schaarbeck, who had fallen back in the course of her work from a height of five feet, striking a solid horizontal bar about the region of the kidneys. Her health previously was invariably fine. The fall produced a luxation between the sixth and seventh cervical vertebrae, showing the spinal marrow, as the autopsy disclosed a complete diastasis of the two vertebrae. The lower limbs and muscles of trunk were completely paralyzed, pulse 120, respiration exclusively diaphragmatic. The unusual feature of the case was the sudden and excessive rise of temperature. One-half hour after accident it was 98 degrees. In twelve hours it was 102 degrees and in twenty-four hours it rose to 109.5 degrees when death ensued. Dr. Lambette draws the conclusion from it that there must be some nerve center in the region of the sixth or seventh vertebra which acts with great energy to control or modify the temperature of the organism. Destroyed by some lesion this center ceases to act as moderator of the temperature, which then rises unchecked, as is proved by the hyperpyrexia following this accident so immediately and to such an excessive extent. No possible infection could have occurred in this case and consequently it proves that fever is not necessarily of microbial origin, but may result from some lesion of a calorific nerve center.

Attention to Sanitary Practice in the Rural Districts.—The *Charlotte Medical Journal* editorially calls attention to the duties of the medical profession to their rural constituencies in the matter of disease prevention. That journal says: "While sanitation has made rapid strides in the great cities, it has not in the rural districts and small towns made the same progress. The principal points wherein reform is needed seems to be in the line of water supply, waste disposal and drainage. The complete abandonment of all shallow wells and the substitution of deep tube wells for isolated districts; for towns, a public supply drawn from uncultivated and uninhabited uplands, and the sanitary supervision of all such districts. In the matter of waste disposal, all privies and cesspools should be absolutely prohibited, and when water carriage is not available, the disposal of excreta by means of the ash or dry earth closet is the only proper method. Slop and wash waters are best disposed of by means of surface or subsoil irrigation over neighboring land; kitchen refuse, etc., should be burned in the range, or what is perhaps better, in a simple open-air furnace made of brick. In country houses, where water service is used, surface irrigation of the sewage, over some near-by field, is the plan to be desired. Drainage, both surface and subsoil, has been much neglected, but it is a potent factor in the healthfulness of a locality; it is really wonderful what

changes are wrought on a moist land by careful underdraining—it is the old story of the Pontine Marshes. The proper preparation of a building site is still another point; many houses of the poor are put down without any cellar, and the residual dampness in such a house can not fail to be a factor in disease. A cellar, five or six feet deep, with the walls properly constructed and a floor, underdrained if necessary, and then covered with several layers of bricks, pitch and concrete, make the proper and only proper foundation for a dwelling. How can these advances in sanitation be accomplished? By educating the people to the proper understanding of the value of sanitary affairs, and this rests with—the family physician.

Practical Testing of the Anti-Erysipelas Serum.—The Paris correspondent of the *Medical Press and Circular* states that Dr. Chantemesse has recently reported on the treatment of 501 cases of erysipelas by serum prepared by the Pasteur Institute, with a mortality of only 2.59 per cent. The effects of the serum are both local and general. Locally, at the end of twenty-four hours, a marked decrease of the redness, swelling and pain, is observed. Desquamation sets in at an early hour consisting of thick epidermic scales. Sometimes the lesion continues to spread but is arrested by repeated injections. Suppuration is very rare and where it existed before the treatment it is considerably diminished by the injections. The general condition of the patient improves rapidly a few hours after the injection; if the dose is sufficient the patient experiences a *bien être* well marked; the nervous disturbance and particularly the delirium are favorably influenced. The fever abates rapidly, to disappear altogether at the end of the second day, while the pulse diminishes in frequency and increases in strength. Where albuminuria has already set in, the injections cause it to disappear within forty-eight hours. The gravity and the duration of the affection are diminished by the serum treatment. The ordinary doses of serum varies between six and ten drams.

Alabama's Embalming Law.—One of the laws passed at the last (1894-5) session of the General Assembly of Alabama created a State Board of Embalming. This consists of five members appointed by the governor. They are required to be practical embalmers, having experience in the business and in the care and disposition of dead human bodies. It is made the duty of the board to prescribe a standard of proficiency as to the qualifications and fitness of those engaged and who may engage in the practice of embalming and the care of and the disposition of dead human bodies. Every person desiring to engage in the practice of embalming dead human bodies, must make written application to the board, accompanying same with a license fee of \$5, and then the applicant, having presented himself or herself before the board at a time and place fixed by it, is, upon due examination, to satisfy the board that he or she is of good moral character, is possessed of a knowledge of the venous and arterial systems, the location of heart, lungs, stomach, womb and other organs in the human body; the location of abdominal, pleural and thoracic cavities; the location of the carotid, brachial, radial, ulnar, femoral and tibial arteries; a knowledge of the science of embalming and the care and disposition of the dead, and has a reasonable knowledge of sanitation and the disinfections of bodies of deceased persons and the apartment, clothing and bedding in case of death from infectious or contagious diseases. To such an one the board will issue a license, which is to be registered in the probate judge's office of the county in which it is proposed to practice, and is to be displayed in a conspicuous place in the practitioner's office. The board is to be paid \$2 annually for renewal of registration. Nothing in this act is to apply to or in any manner interfere with the duties of any officer of local or State institutions, nor to any person engaged simply in the furnishing of burial receptacles for the dead; and the act

itself is only to apply to cities and towns having a population of 1,500 or over. The penalty for practicing or holding one's self out as practicing the science of embalming without having complied with these provisions is a fine of not less than \$50 nor more than \$100 for each offense, which goes to the public school fund.

Kitasato's Work in 1895 in Serotherapy.—Dr. Nakagawa writes to the London *Lancet* on the above subject, stating that Kitasato has lately published a detailed report of 353 cases treated at the institute with the serum prepared under his supervision. For those who have no access to the original a few brief extracts may be of some interest. Rate of mortality may be learned from the following: "Kitasato has collected from reliable sources 26,521 cases of diphtheria in Japan previous to serotherapy, with 14,996 deaths (56 per cent.); while of 353 cases treated here from Nov. 1894, to Nov. 25, 1895, there were only 31 deaths (8.78 per cent.). There is reason to believe that the mortality can be lowered if the treatment could be commenced early in the course of the disease. Thus in 110 cases in which injections were made within forty-eight hours after the invasion all ended in recovery. On the other hand, of thirty-three cases treated after the eighth day of the disease eleven were lost. Some of the patients were brought into the institute in a moribund condition, and six children died within five hours after admission, six more within ten hours; altogether twenty-one cases (two thirds of the total mortality) were lost within the first twenty-four hours. As to the effect of the serum on the course of the disease the first to be noted is: 1. The fall of temperature; in many cases the defervescence was almost critical, and, it takes place usually at the end of twenty-four to forty-eight hours. 2. The separation of the false membrane, which takes place as a rule after the return of the temperature toward the normal. Very large casts of the trachea and larger bronchi have been coughed up. 3. Urticaria-like eruptions were observed in very many cases, being in some quite severe and annoying. They, however, disappeared in a few days without any treatment. 4. In four cases marked albuminuria was observed at the time of admission. In these cases albumin disappeared from the urine in the course of the treatment. Pyrexia was accompanied by albumin in the urine, but there was no reason to believe that any renal trouble was caused by the injections. 5. Five cases developed paresis of the soft palate. I wish to note, in conclusion, that microscopic as well as culture examinations were made in every case, and Dr. Kitasato's report only deals with those cases in which Löffler's bacilli were demonstrated to be present."

Localization of the Variolous Eruption.—While smallpox is still prevalent in many parts of the country it may be worth while again to call attention to the procedure which has been more or less frequently resorted to for nearly half a century with a view of localizing the eruption on the trunk of the body and so save pitting of the face as well as reducing the dangers of corneal inflammation. Dr. George O. Butler in the May number of the *Cleveland Journal of Medicine* recounts that his attention was attracted to this method by a confederate surgeon at Frankfort, Ky., during the winter of 1863. His mode of treatment was, so soon as a case was diagnosed variola or varioloid, to apply a cantharidal plaster about ten or twelve inches square upon the anterior aspect of the thorax. As soon as vesication ensued, he would apply a flaxseed poultice, remove the cuticle, reapply the poultice for a day or two, then dress the blistered surface with savin cerate. The discharge from the raw surface was profuse. In addition to this local treatment cathartics, diuretics and diaphoretics were used as required. Dr. Butler observed this procedure in at least fifteen or twenty cases. The papillæ or red pimples, as large and hard as a birdshot, would disappear as soon as the blistered surface discharged freely.

There were no vesicles or pustules observed whenever the cantharidal plaster was applied before or during the papular stage. Two of the cases were treated without the local application, and they developed into typical cases of discrete smallpox. In some few cases vesicles were visible, and would dry up and disappear as would a varicella, the vesicle leaving no scar or pit. The duration of the disease was materially shortened, none being confined to bed longer than one week. During the following winter (1864), the disease appeared in Cleveland in an epidemic form. Dr. Butler had then returned and resumed practice and was fortunate enough to treat some twenty cases at their homes under unfavorable circumstances. He adopted the forgoing treatment, with recovery in each case without pits or scars, excepting upon the blistered surface which presented an immense pitted scar or cicatrix. In only one case were more than five or six visits rendered. Dr. Butler adds that he made some notes during Prof. A. C. Ackley's lecture on smallpox in the year 1853, wherein the application of an ointment composed of croton oil and tartar emetic was recommended for a similar purpose; and also that he was informed that previous to the war of the rebellion the physicians in the West India Islands pursued the blistering treatment with like results. In his history of the smallpox epidemic in Illinois, 1881-1883, the late Dr. John H. Rauch called attention to a case of smallpox reported by Dr. Charles Caldwell, in which two days before the eruption made its appearance the patient had a sore throat and applied a towel saturated with kerosene to the neck. Dr. Caldwell says: "When the eruption came out the pustules were all on the neck. If we only knew at the time that the patient was going to have the disease a blister or other counter-irritant to some part of the body might save the face." In a footnote to this case Dr. Rauch says: This expedient was in use in the Vienna General Hospital in 1863 (Schmidt's *Jahrbücher*, Band 133) and about the same time by Dr. Lyndon a confederate surgeon. (*Medical and Surgical Reporter*, vol. xlvii, 1882.)

Practical Notes.

Chewing-gum the Nucleus for an Appendicitis.—A youth of 18 years, of Peekskill, N. Y., was taken suddenly and seriously ill with an attack that was diagnosticated as appendicitis. An operation was performed and the diagnosis confirmed. The appendix was found to be ulcerated and perforated. It was removed and in it was found a globular piece of chewing-gum, upon the surface of which adhered a vast number of particles of partly digested food, making a lump about the size of a walnut. The recovery of the young man is still in doubt.

Stephen Smith's Amputation at the Middlesex Hospital, London.—The *Medical Press and Circular* gives an abstract of a clinical demonstration at the Middlesex Hospital of the above operation for the relief of thrombosis of popliteal and femoral arteries and gangrene of leg. The patient was a male, aged 57 years, but looking much older. Occupying the middle third of the outer surface of the patient's right leg was an ulcer more than six inches long, extending down to the interosseous membrane, to the tibia and the fibula; this was caused by gangrenous inflammation; the slough had nearly all separated, but the exposed outer surface of the tibia was necrosed. The foot was very edematous. Pulsation was felt in the femoral artery down to the apex of Scarpa's triangle, below which no arterial pulsation could be detected. The leg was removed at the knee-joint below the semilunar fibro-cartilages, the stump being covered in by lateral flaps taken from the leg according to the method of Stephen Smith. The femoral artery was found filled with a dark red thrombus; the arterial wall was not notably thickened or otherwise diseased. Mr. Gould said it was necessary in these days for a surgeon to justify very completely every amputation, but he believed that in this case there

was no other course opened to him to pursue. The existence of the thrombosis, together with the feeble state of the patient, rendered it probable that the ulceration would never heal, but even were healing to be obtained, the man would be left with a useless and troublesome leg. The extensor and peronei muscles were destroyed, so that the foot would be in a condition of paralytic equino-varus; and the anterior tibial and musculo-cutaneous nerves having also been destroyed, the dorsum of the foot would be deprived of all sensation, and would probably become quickly the seat of trophic sores. Having decided to amputate, the question arose as to the best method to adopt. He has chosen Stephen Smith's amputation through the knee-joint because it was attended with less shock and less hemorrhage than any amputation through the lower part of the thigh; if successful it would leave the man a better stump than an amputation further up. In the patient's feeble state Mr. Gould attached great importance to the little shock and trifling hemorrhage (in this case not amounting to half an ounce), and this was the chief reason that had weighed with him in his decision. He was aware, however, that this operation was in this particular patient attended with risk; the flaps of skin and fascia which he had reflected from the leg were very thin, and at the same time were of necessity long, and with thrombosis of the popliteal and femoral arteries there was danger that one or both these flaps would slough. He pointed out that the outer flap, owing to its less free blood supply, was more liable to slough than the inner flap. In speaking of the thrombosis, he drew attention to the probability of its being due to an extension of clot from the anterior tibial artery, the seat of disease, and not to extensive disease of the arterial wall, the disease differing wholly from another he mentioned, in which he recently performed the same operation for gangrene of the leg due to obliterative arteritis, and in which the popliteal artery was found to be filled, not with thrombus, but with organized fibro-cellular tissue.

Detroit.

THE COMMITTEE on medical legislation appointed by the medical societies of this city and State, met May 1. The name adopted was the Michigan League for Medical Legislation. The membership was extended to include any practitioner and the vice-presidents are to be one from each pathy. The second meeting will be held on May 8, for the election of permanent officers.

THE REPORT from the Health Officer for the week ended May 2, gives: Deaths 76, under 5 years 30; births, male 44, female 41. Contagious diseases: Diphtheria, 8 new cases, 2 recovered and none died: scarlet fever, 4 new cases, 11 recovered, none died.

THE DETROIT COLLEGE OF MEDICINE surprised its senior class this year by requiring every member of the class to write upon the final examinations. This was in the face of the fact that the regulations of the college allow that all whose standing for the term reaches a standard of 85 per cent. shall be exempt from final examination and following out this rule, last year's senior class were all allowed to pass except some half dozen men who were obliged to take a final. There were 79 graduates.

THE ANN ARBOR (Mich.) HOSPITAL which is at present crowded will probably remain open during the summer months.

Washington.

HEALTH OF THE DISTRICT.—The following report by the Health Officer for the week ended April 18 is made: The mortality of the District during the past week reached 116. In the previous week it was 112. The death rate was 21.90, as against 22.67 during the same period last year. Both the health and meteorological conditions evinced unusual variations from those of the last report. The mean temperature rose 28 degrees over that previously reported, and stood at a mean of 70 degrees. Accompanying the high temperature was

a high barometrical pressure, with southerly mild breezes, and with an almost even relative humidity. The maximum temperature for the week was 93 degrees and the minimum 37 degrees; range 56 degrees.

THE INEBRIATES BILL RECOMMITTED.—The bill to provide for the care and cure of inebriates in the District of Columbia was reported to the Senate adversely April 17 last and postponed indefinitely. On the 24th ult., a motion to reconsider was agreed to, and the bill was recommitted to the Committee on the District of Columbia.

SMALLPOX HOSPITAL.—The Commissioners have sent to Congress a recommendation that the following proviso be added to the item in the pending deficiency bill making appropriation to complete the smallpox hospital: "That the Commissioners of the District of Columbia are authorized to make rules and regulations for the government of the smallpox hospital, and to charge reasonable prices for the use of private rooms therein (when such use is not rendered necessary by the condition of the patient) and for the accommodation of persons not afflicted with smallpox, but allowed to enter said hospital in company with relatives or friends who are so afflicted."

MEDICAL VALUE OF THE X RAYS.—Prof. J. J. Kinyon, of the Marine-Hospital Service and professor of bacteriology of the medical department of Georgetown University, is conducting an interesting series of X-ray experiments before the medical students of Georgetown University at the medical department.

STAFF OFFICERS AT THE EMERGENCY HOSPITAL.—At the annual meeting of the attending staff of the Central Dispensary and Emergency Hospital, held on the 2d inst., Dr. Swan M. Burnett, was re-elected President, and Dr. W. H. Hawkes was elected to fill the office of Secretary. Both have held the office for the past twelve years.

WOMAN'S CLINIC.—The Board of Directors of the Woman's Clinic held their quarterly meeting at the hospital on the 2d inst. The reports of staff and officers showed the work of the institution to be on a steady increase.

WASHINGTON OBSTETRICAL AND GYNECOLOGICAL SOCIETY.—At the 246th meeting of the society held on the 1st inst., Dr. John Van Renselaer read a very interesting and instructive paper, with cases, on venesection and infusion of saline solutions in the treatment of uremic coma. A very full discussion followed.

TO ESTABLISH HARBOR REGULATIONS.—Mr. Babcock has introduced a bill in the House to establish certain harbor regulations in the District of Columbia. Under this bill it will be unlawful for any owner or occupant of any wharf or dock, any master or captain of any vessel, or any other person, to throw any dirt, ballast, oyster shells, vegetables, dead animals or ashes into the Potomac within the District limits, or on its shores below high water mark, unless for the purpose of making a wharf, duly authorized by the Commissioners. A violation of the act shall be punishable by a fine in the police court, not exceeding \$100 or imprisonment for six months, or both.

TO REGULATE NEW MEDICAL COLLEGES IN THE DISTRICT.—The Commissioners have returned to the President, with their approval, the bill regulating medical colleges. Under this bill all colleges will be required to first obtain a permit before opening their doors. The bill is aimed at quack institutions, which bestow diplomas without any other requisite save the payment of a small fee.

Cincinnati.

THE CELEBRATED PEARL BRYAN CASE is attracting much attention in the medical profession, owing to the amount of expert testimony being introduced. The questions as to whether the head was cut off before or after death, whether the deed was committed in Ohio or Kentucky, where the body was found, or what rôle the cocaine found in the stomach might play in the murder. The claim being made by the defense that they had administered cocaine to the girl in Cincinnati for the

purpose of producing or assisting in an abortion, and that while under this anesthetic she died, and the defense is therefore only guilty of manslaughter in the State of Ohio, the limit of punishment of which is seven years, while in Kentucky the same crime is a capital offense. The weight of expert testimony tends to prove that on account of the amount of blood found with the body, and the leaves surrounding the same being spattered with blood, the decapitation was done at that spot. It was also claimed that cocaine has not been successfully used to produce an abortion, or to hasten labor, by the profession. Both defendants are dental students.

A CASE IN THE CRIMINAL COURT last week brought out a delicate medico-legal question. A man being charged with shooting another offered the defense that the hospital authorities were responsible for his death, by reason of their negligence in the treatment of the case. The man was shot in the left side of the chest, the ball grazing the sternum, deflecting to the left, penetrated the pleura and lung and shattered a posterior portion of the rib. He died five days after, and the autopsy revealed death from progressive hemorrhage with a consolidation of the lung. The claim is made that had this case been properly operated upon at the time of the accident he would in all probability have recovered.

A CASE OF VARILOID turned up in the city last week and was taken to the Branch Hospital.

A YOUNG CHILD was received at the City Hospital last week suffering from a foreign body in the larynx. Tracheotomy was performed shortly before the child died. The autopsy revealed a large bean at the bifurcation of the bronchi.

THE ACADEMY OF MEDICINE adopted the report of the committee on "Directory for Nurses," and Sister Anna Kypke of the Losanti Sisters has been placed in charge of the registration, under the supervision of a committee consisting of Dr. R. W. Stewart, Dr. D. I. Wolfstein and Dr. G. M. Allen. The registration will be at the "Losanti," and when a nurse is called her name will then be placed at the bottom of the list, thus insuring impartiality in the selection of the nurses for calls.

THE INVESTIGATION of the Dairy and Food Commission by the Senate Committee has been completed and the committee has reported that it has failed to find where Dr. McNeal has neglected to endeavor to enforce the pure food laws, but that the preponderance of evidence goes to show that Amos Dye should be dismissed as counsel for the Commission on account of his connection with Mr. White, of "Paskola" fame, in the matter of a \$5,000 bribe alleged to have been made by Mr. White.

DR. D. W. YOUNG demonstrated before the Academy of Medicine the advisability of making traction in the line of the body in a case of dislocation of the head of the humerus with fracture of the surgical neck.

THE LEGISLATURE has passed the bill permitting the Medical College of Ohio to transfer its property and chattels to the Cincinnati University and become its medical department, thereby losing its identity as a medical college, and the building formerly occupied by the University will be used for the medical department. An important supplementary bill passed during the last day of the Legislature was one enabling the University to charge tuition in all departments except the academic, which must remain free to bona fide citizens of Cincinnati under the terms of its endowment.

THE MORTALITY REPORT for the week ended Friday, February 17 shows: Membranous croup 1, diarrheal diseases 3, diphtheria 2, measles 5, septicaemia 3, typhoid fever 5, other zymotic diseases 1; cancer 1, phthisis pulmonalis 9, other constitutional diseases 6; apoplexy 1, bronchitis 2, convulsions 5, gastritis 3, meningitis 8, nephritis 3, peritonitis 1, pneumonia 21, other local diseases 25; deaths from developmental diseases 7, violence 9; under 1 year 29; from 1 to 5 years 16; from all causes 137; annual rate per 1,000 20.35; deaths during preceding week 112; corresponding week 1895, 115; 1894, 120; 1893, 113.

THE PUBLIC SERVICES.

Army Changes. Official List of changes in the stations and duty of officers serving in the Medical Department, U. S. Army, from April 25 to May 1, 1896.

Capt. Aaron H. Appel, Asst. Surgeon, is relieved from duty as attending surgeon at Chicago, Ill.

Capt. Julian M. Cabell, Asst. Surgeon, will report in person to the president of the Army retiring board at Ft. Columbus, N. Y., at such time as he may designate, for examination by the board.

First Lieut. Benjamin Brooke, Asst. Surgeon, is relieved from further duty at Ft. Canby, Washington, and upon completion of his examination for promotion will proceed to Ft. Thomas, Ky., and report for duty at that station.

Capt. Guy L. Edie, Asst. Surgeon, will, upon the expiration of his present leave of absence, report for duty at the Presidio of San Francisco, Cal.

First Lieut. George J. Newgarden, Asst. Surgeon, is granted leave of absence for twenty-one days, to take effect upon his relief from duty at Fort Wayne, Mich.

First Lieut. Powell C. Fauntleroy, Asst. Surgeon, is relieved from duty at Ft. Riley, Kan., and ordered to Ft. Grant, Ariz., for duty at that post.

First Lieut. James S. Wilson, Asst. Surgeon, is relieved from temporary duty at Madison Bks., M. Y., and ordered to Ft. Clark, Texas, for duty at that post, relieving First Lieut. Isaac P. Ware, Asst. Surgeon. First Lieutenant Ware, on being thus relieved, is ordered to Madison Bks., N. Y., for duty.

The order detailing medical officers of the Army to attend the annual meeting of the American Medical Association at Atlanta, Ga., May 14 to May 16, 1896, is amended to direct them to attend said meeting from May 4 to May 6, 1896.

Navy Changes. Changes in the Medical Corps of the U. S. Navy the week ending May 2, 1896.

P. A. Surgeon H. N. T. Harris, detached from the "San Francisco," proceed home and granted three months' leave, with permission to leave the United States.

Asst. Surgeon F. M. Shipp, ordered to examination for promotion May 9 at New York city.

Medical Inspector G. F. Winslow, ordered to New London Station May 9.

Surgeon Clement Biddle, detached from the New London Station May 9 and ordered to the "Monongahela" May 14.

PROMOTION.

Asst. Surgeon J. M. Moore, promoted to Passed Assistant Surgeon, April 29, 1896.

Change of Address.

Brainard, B. F., from Kansas City to Martin City, Mo.

Brown, J. S., from Bear Polar to Salisbury, N. C.

Bannister, H. M., residence from Austin to 222 Harvey Ave., Oak Park, Ill.

Connell, D. R., from Chicago to Davis, Ill.

Dobson, S. J., from Chicago, Ill., to Jefferson, Kan.

Eaton, F. B., from Portland, Ore., to care Gordan W. A., San Jose, Cal.

Franklin, W. A., from Omaha to Leroy, Neb.

Gradle, Henry, from 65 Randolph St. to Room 608, 100 State St., Chicago, Ill.

Hayd, H. E., from 78 Niagara St. to 493 Delaware St., Buffalo, N. Y.

Hakanson, A., from 746 Cokes Ave. to 153 92d St., Chicago, Ill.

Harris, M. L., from Chicago Opera House Bldg. to 612 Reliance Bldg., Chicago, Ill.

Jordan, J. D., from Madisonville, Texas, to 819 W. Harrison St., Chicago, Ill.

Kuh, Edwin J., from 3415 Prairie Ave. to 4330 Drexel Boul., Chicago, Ill.

Kleith, Wm., from Chicago, Ill., to Columbus, Ohio.

Lundholm, E. M., from 329 E. 7th St. to 438 Sibley St., St. Paul, Minn.

Nason, J. E., from Sharpsburg to Taylorville, Ill.

McKeedy, W. C., from 2194 7th Ave. to 27 Whitehall St., New York, N. Y.

Maynard, F. B., from Sandy Hill to Brockport, N. Y.

Murrell, T. E., from St. Louis, Mo., to Albuquerque, N. M.

Mullen, T. R., from Omaha, Neb., to Marcus, Iowa.

Northrup, F. A., from Chicago, Ill., to 351 Scott St., Milwaukee, Wis.

Piper, R. J., from 160 State St. to 480 Grand Boul., Chicago, Ill.

Winn, G. L., from 435 W. State St. to 317 Wm. Brown Bldg., Rockford, Ill.

ADDRESSES.

THE RELATIONS OF MEDICAL EXAMINING BOARDS TO THE STATE, TO THE SCHOOLS AND TO EACH OTHER.

Presidential Address before the National Confederation of State Medical Examining and Licensing Boards, at its Sixth Annual Meeting held at Atlanta, Ga., May 1, 1896.

BY WILLIAM WARREN POTTER, M.D.

BUFFALO, N. Y.

EXAMINER IN OBSTETRICS, NEW YORK STATE MEDICAL EXAMINING AND LICENSING BOARD.

In assuming the duties of this chair my mind instinctively reverts to its first occupant, who as you all well know was the founder and organizer of this confederation, a pioneer in medical educational reform in this country, an earnest and forceful advocate of every reasonable method of advancing the standard in the United States. Though he was our leader he was also our companion and friend, and if he were yet living he would most likely continue to occupy the chair. To be regarded as worthy of the succession is an honor that I fully appreciate. Let us always keep green the memory of John H. Rauch.

INTRODUCTION.

There is food for much thought in assuming the direction of the affairs of this organization. It is a body unique among medical societies. It is without a parallel in medical history and has not even a complete record of its own work. This fault, however, I hope will not occur hereafter. The chief function of the confederation is to discuss questions relating to medical examinations for license, but it can not bind its members to follow its recommendations; nor does it so desire. In order to make the work of such a body effective all adhesion to it must be voluntary in character, not coercive.

There are, however, many collateral questions to consider if not to settle, but everything must be done with circumspection. We are on the threshold of new conditions. We may, therefore, with great propriety adhere to if not adopt for our guidance the ancient maxim, *festina lente*. We are without traditions, without precedents, without heredity. There is much wisdom, then, in making haste slowly that we may proceed to accomplish the end sought all the more surely.

POINTS OF AGREEMENT.

Of one thing I assume we are quite certain—namely, that there are no differences of opinion among physicians even of the several so-called systems of practice recognized by law—intelligent physicians—as to the propriety, even the necessity, of improved methods in medical education and increased standards of acquirements for entrance to the profession of medicine. It has taken considerable time and it has occasioned some severe contention to even reach this first landing-stage, but I think we are all

agreed at last on this point and I also believe the agreement will endure.

As to just what these reforms ought to be may not yet have been determined with unanimity, but I shall assume that all of the class named are of one opinion on some that are necessary. One of these is that there must be a better standard of academic preliminaries; another that ought to bring us together is that four years is quite short time enough to be devoted to medical collegiate training; and still another we ought to be united upon is, that an examination of each graduated physician by the State, separate and apart from the schools, is a necessary condition precedent to obtain a license to practice. These are three cardinal principles it seems to me on which reforms ought to be grounded, and it ought to be possible for all physicians to unite in an effort to secure legal enactments in all the States establishing these essential principles.

PRELIMINARY REQUIREMENTS.

In regard to preliminary requirements for matriculation in a medical school, there may be some difficulty in establishing all at once in every State a standard as high as it should be, but it seems as if we might agree upon a minimum below which no person may enter upon the study of medicine. It is as requisite for a physician to possess an education as it is for him to be a gentleman.

For myself I would insist that a high school diploma ought to be regarded as an index of the lowest limit of literary attainment for the novice. An entrance examination should be required of all who do not possess such a diploma or its equivalent, such examination to be conducted independently of the medical colleges. As I would have the graduate examined by the State for license separately and apart from the college, so I would have the candidate for admission to the study of medicine also examined by the State to determine his qualifications to enter upon that important duty. In other words, the State has the right to determine the qualifications of all who enter upon the practice thereof, and I am in favor of its exercising both functions.

Not until after four years study in a recognized medical college and the receipt of a diploma therefrom should a physician become eligible to license by the State, and then only after due examination by its medical examiners, none of whom should be medical college teachers. It has been claimed by some teachers that State examiners are neither competent to propound proper questions nor to mark them at their true value,¹ but I need not absorb valuable time in the discussion of a question that seems to be already definitely settled in the affirmative.

LIMITATIONS OF STATE CONTROL.

Thus the State again steps in and exercises her right to determine as to the adequacy of the training

a physician has received in the schools, and it issues a license to practice only to those found qualified. Hence, there are three stages of preparation for medical practice: 1. a preliminary training that shall at least equal that of a high school graduate; 2. four years' study in a legally incorporated medical college; and, 3. examination and license by a State board, none of whose members are teachers in a medical college.

In two of these stages the State plays an active part—namely, in the first and the last. The State must determine as to the competency of those who enter upon the study of medicine and also the qualifications of those who are admitted to practice. But this is the limit of the State's authority; beyond this it may not interfere; that is, it is not competent for the State to interpose its authority during the medical collegiate life of the student. Here the teachers are supreme and must be left untrammelled. They must be allowed perfect freedom to teach in their own way. Their function is to teach their students so well that they may pass any of the State boards, and they may be trusted to do it, else they will suffer not only the humiliation of rejected candidates but their classes will diminish in size, and, except in the endowed schools, their incomes will correspondingly shrink. Students will not be slow to detect this nor to select the medical college that will prepare them to obtain the State license with certainty.

While, therefore, the State may not interfere, as we have said, during the four years of medical college training, it yet exercises a watchful care in granting charters to medical colleges, issuing them only where the applicants are shown to be teachers of undoubted competence and men of integrity. A State must also be sure that the number of schools is not too great within its boundaries. Moreover, it should specify the essentials to be maintained, such as laboratories for teaching chemistry, physiology, anatomy, bacteriology and the like; also, that clinical teaching must be pursued and that hygiene, preventive and State medicine, and lastly, clinical midwifery must be taught,—the latter to the extent that each graduate must have attended at least six cases of labor.

SHALL THE EXAMINATIONS BE DIVIDED?

It has been held by some that it would be better to divide the State examinations, and at the end of the second year let students come up before the State board for examination in the so-called fundamental branches— anatomy, physiology and chemistry. This would unload the mind, say the advocates of this plan, of a great anxiety, and thus better prepare students to cope with the practical subjects— surgery, obstetrics, practice, materia medica, pathology and hygiene. It is doubtful if the State can legally lay its hands on a student after he has passed the entrance door of a medical college, even for the purpose of compelling a division of the examination such as has been proposed. The most it could do in the premises would be to *permit* him to take an intermediate pass examination if he so desired; but unless this were made compulsory it would doubtless fail to commend itself to any considerable number and so fail of its purpose. Besides, it could not be made to apply to foreigners or to students from other States. Taken altogether this plan may be said to be not only impracticable but most likely impossible to establish. Moreover, the theory of the State examination is that it is a post-graduate scrutiny and not an undergraduate test.

A QUARANTINE AGAINST THE UNQUALIFIED.

The number of States that in some manner supervise the practice of medicine is now proportionately large² and it is constantly increasing. Ohio is the latest convert and it is a genuine pleasure to welcome her to the fold. Our friends in that great commonwealth have occupied a trying position for some years, but at last have scored a good start and under the discreet leadership of able men who are handling the reins will reach the goal. Under the ratio of progress now making it will not be long before all the States will in some form or other establish a quarantine against unqualified doctors. But the great desideratum is to persuade each and every State to enact laws that shall require separate examination after graduation in order to obtain license to practise. Until each State shall deny the right to practise, except through license obtained on due examination and after graduation from a legally incorporated medical school requiring academic preliminaries and a four years' course, the struggle must continue.

By a law of the State of New York passed March 21, 1896, it is provided that all candidates for admission to the State examination must have studied medicine not less than four full *school years of at least nine months each*, including four satisfactory courses of *at least six months each*, in four different calendar years in a medical school registered as maintaining at the time a satisfactory standard. This section is to take effect Jan. 1, 1898. It is further provided in the same act that New York medical schools and New York medical students shall not be discriminated against by the registration of any medical school out of the State, whose minimum graduation standard is less than that fixed by statute for New York medical schools.

It will be readily understood, in the light of the foregoing extracts from the statute, how impossible it is for New York to recognize the licenses of any State that maintains a standard lower in any respect than its own. Nevertheless, whenever any State shall demand the same preliminaries and equal collegiate training, with a commensurately high final examination, certainly it then will be a pleasure for New York to establish reciprocity with it.

It is not my purpose to forestall the discussion on the question that is to come up later at this meeting, but it is not easily possible to omit some mention of this important subject, inasmuch as it is just now very much in evidence all over the country. New York has been criticised³ by other States for not recognizing their licenses, but her position in refusing to indorse the licenses from States where the standard is lower must be conceded to be impregnable. To recognize licenses from States in which the requirements are less would be to deal unjustly with her own citizens, and to yield advantages over them to those coming from without her boundaries.

A NATIONAL LICENSING BOARD.

Another question that has been raised in certain quarters is the propriety of creating a national licensing board. Dr. C. E. Farnum, of San Francisco, I believe, has suggested that such a board be detailed from the medical corps of the army and navy⁴; and that the licensees of this board receive a degree or title similar to the English F. R. C. S., such, for instance, as "Fellow in Medicine and Surgery."

It seems to me that a national examining and licensing board is not only unnecessary but quite im-

practicable at present, and I doubt if it ever becomes a measure of expediency. Up to the present, Congress has very wisely interpreted the Constitution to relegate police regulations to the several States and has declined to interfere in such matters. The power of Congress to create such a board, even were it so disposed, is seriously questioned by well-informed men both of the legal and medical professions. Moreover, the vast machinery required to carry on the work of such a board in territory of such wide domain as ours, would at once suggest an adequate reason for condemning the scheme even if there were no other. As to the proposition of our friend from the Pacific coast to create a board from the public services that shall have power to confer a special degree, it would appear to most of us, I am sure, that our essential need now is fewer degrees and better education. Furthermore, we need not superimpose this Herculean task upon our good friends of the medical corps of the army and navy in addition to their already burdensome duties and responsibilities.

Let us wait then until the States themselves—those that have not already done so—advance their standards to the line of requiring preliminary education equal to a high school course, four years' medical collegiate training and a separate State examination for license after graduation. When this is done in our fifty-three States and Territories⁶ it will be quite time enough to delegate to the general government the duties and powers now exercised by each State in this matter.

A UNIFORM MINIMUM STANDARD OF REQUIREMENT.

While, therefore, it is practically impossible at present under existing laws to establish a uniform minimum standard of requirements in all the States, there is yet hope that year by year this desideratum may be more nearly approached until ultimately it is attained. Amendments to imperfect laws must be fostered and States without practice laws must be encouraged to enact them, to the end that their citizens may not be discriminated against by the other States.

It has been suggested that a committee of supervision might be created by the examining boards in those States that require examination after graduation for license, forming a syndicate and each appointing a representative to such central body. The duties of this committee merely would be to formulate a uniform standard for the guidance of the State Boards represented in the committee. As fast as States enacted or amended their laws to meet the established grade of requirements, their boards would be entitled to representation on this central committee; so, whereas only a small committee at first would be created, in the end it would comprise a membership equal to the whole number of States and Territories.

RECIPROCITY OF LICENSURE.

Between the States represented in this committee, of course, there would be established a reciprocity of licensure. But let us pause for a moment, to inquire as to the necessity of desirability of reciprocity. I confess that I am not among the number that regard reciprocity as of great importance. Whenever a sufficient number of States shall advance their standards to a common minimum level of requirements, and these shall demand first, a high school course as an entrance minimum; second, four years' medical collegiate training as a condition for a medical degree; and, third, a separate post-graduate examination for license—when, I repeat, these shall be the requirements for

the practice of medicine in at least twenty States, it will by quite time enough for these commonwealths to establish reciprocity among themselves. Until then let the migratory physician pay the penalty of his itinerancy by taking the examination of his new sought State. If he is well equipped he will be perfectly willing to do so; if not then let him seek another occupation. Whenever twenty States shall form such a reciprocal syndicate it will not then be long before the others in self-protection will advance their standards to the minimum these shall have established.

THE STATE SHOULD EMPLOY ONLY LICENSED PHYSICIANS.

It is impossible to create new conditions such as we are entering upon without meting out hardship to some. All border-line students and young physicians naturally feel themselves aggrieved, and they vehemently demand special rulings or statutes to fit each particular case. But we must begin somewhere to draw the line between the old way and the new, and the few ought to yield gracefully to the many. The particular good must not stand in the way of the general good.

The State is ever jealous of her rights and of the welfare of her citizens. She is particularly so of their health, which means economy. She has assumed to decide who shall and who shall not minister to the sick and injured and she especially has determined to administer the laws of prevention with a constantly increasing rigidity. Her public health officers must be men of education and executive capacity. It will not be long, I trust, before no person will be commissioned in any of these great offices who does not possess a State license. If this were made the rule we would soon hear less complaint in regard to the State examination: while, on the other hand every spirited young graduate would be anxious to take it. Such action would tend to remove prejudice against the system and would in many ways strengthen the hands of those who are engaged in this reform.

HOW SHALL FOREIGNERS BE DEALT WITH?

One of the difficult problems confronted is in dealing with foreigners. These men come to this country in large numbers without knowledge of our language, where they are told that everything is as free as air, hence they expect to be admitted to practice at once without let or hindrance. Finding a State examination necessary they plead poverty and demand leniency because of their imperfect knowledge of the English tongue. The question presented may be formulated about as follows: "Shall one rule be established for our own countrymen, and another less rigid for these strangers?" I trust not and I hope the answer will be a unanimous negative. The injustice of such discrimination against our own citizens is too apparent to admit of argument. I would not make one rule for one class of candidates and another for another class, but I would administer the laws with impartiality, governing all alike.

If one of our fellow-citizens should present such examination papers to a foreign board as these men generally offer to most of ours, he would be denied even the semblance of a hearing. His application would be dismissed without ceremony. Let it be remembered in connection with this that the country is not suffering for the want of doctors, and can wait without material injury until these men shall master the English language and otherwise conform to

our rules—until they can place themselves on the same footing in every respect with our own countrymen. When they present themselves in a clear identity, with a legal diploma properly authenticated, and take our examination successfully, then we will gladly issue to them licenses to practice, but they should be made to understand at once that they can obtain them in no other way. This question is attracting the attention of medical journals in different sections of the country and has lately been discussed by one "in a most decided and uncompromising manner.

BOARDS NOT ANTAGONISTIC TO THE COLLEGES.

It has been asserted in certain quarters that the State boards are antagonistic to colleges, that they are setting up standards of their own, and that their rules are oppressive to the schools. Nothing, in my view, could be further from the truth. The real facts are that the boards and the colleges are working along parallel lines to accomplish the same end—namely, an improvement in the quality of physicians admitted to practice in the United States. Moreover, there is a harmony of action between them that is remarkable, considering the radical changes that have necessarily been wrought in methods of teaching as a result of the practice laws. If the schools in many instances have waited for mandatory laws to raise their standards and increase their years of study, that is because the rank and file of a great profession has risen in its might, and through its constituted State medical societies has demanded laws of the several State legislatures that should advance the cause of higher medical education. The examining boards are merely the servants of the people in this matter, are simply instruments through which their will obtains definite expression.

There can be no antagonism against the schools in this needful reform. They are as much interested in it as are we. We are not enemies but friends. The college teachers are more than glad to be relieved of much of the detail of educational reform, and thus to be enabled to address themselves solely to clinical, laboratory, recitative and didactic teaching. They prefer not to concern themselves about entrance examinations, thus avoiding the thousand and one questions that are constantly being put by the students on this and kindred subjects relating to detail. The object of the schools is to see to it that young physicians are properly equipped to practice medicine, while the purpose of the boards is to determine that physicians have been adequately instructed to merit a State license.

In a recent conversation a distinguished teacher in one of the first medical schools in the land remarked: "The faculty of which I am a member desires to teach our pupils so well that they may be enabled to pass any examining board—army, navy or State. If perchance we fail to do so now and then, or if some escape our scrutiny, we are only too glad to have the State board reject such and send them back for further training. We approve of the good work done by the examining boards, and are glad to have them supervise our methods to the end that incompetent doctors may not be sent out from our college." Words of this character coming from such a distinguished source can not fail to do good. They express the entire relationship that ought to exist between the schools and the boards. If teachers all felt this way and so expressed themselves whenever occasion pre-

sented, it would serve to strengthen the hands of the examiners, increase their usefulness, and so benefit the cause of educational progress.

I fear, however, teachers in many instances have engendered in the minds of students a dread of the boards and, by innuendo if not by words, belittled their work.⁷ Students are taught in some schools in a way to lead them to suppose that the only object of colleges is to prepare them to successfully compete for the State license. It is forgotten, apparently, that the real aim should be to teach them how to be good physicians. If they would stimulate in their classes a respect for the boards and instruct them that the State license is a parchment to be highly prized and eagerly sought, it would tend to create an atmosphere around them that would prove of lasting benefit to the cause. It affords me pleasure, however, to refer in this place to two notable exceptions to the condition I have just delineated. Professor Hinkel, of Buffalo, devoted his introductory lecture to a college course, not long ago, to the subject of State examination for license,⁸ in which he fully set forth the system in operation in New York, and instructed the students as to the importance of the measure. Professor Tucker, of Albany, chose as the title of his opening lecture last fall at the Albany Medical College: "State Control in Medicine."⁹ He, too, carefully analyzed the new system and gave deserved credit to the examining boards. There are undoubtedly many similar instances where teachers have taken occasion to speak well of examinations by the State for license, but I need not refer to this subject in greater detail at this time.

MEDICAL JOURNALS ARE AIDING.

It is a satisfaction to know that the medical periodical press is very nearly unanimous in its support of the principles advocated in this paper. Moreover, it is an active ally that is constantly busy in disseminating information on the subject, and urging on the most efficient and highest order of reform. While it is true that at first many were skeptical, some were lukewarm, and a few were open enemies of the scheme, now it is a pleasure to affirm that there is not a single medical magazine, weekly or monthly, between New York and San Francisco and from Maine to Texas,¹⁰ which is not an aggressive coadjutor, while many are propagandists of the faith. These magazines are leaders in thought and molders of opinion, and under their influence we may hope soon to advance and unify standards until all States and Territories of the Union will practically establish the same requirements for obtaining license to practice.

A VOICE FROM THE TRANSVAAL.

A strong argument for uniformity of methods and standards throughout the Union is presented, incidentally, in a recent letter addressed to the *Medical Record* by Dr. Gordon Messum, chairman of the Transvaal Government Medical Board. The rule followed there is for the board to register only such physicians as present diplomas which entitle the legitimate holders to practice in the whole of the country where such diploma has been issued, and for which a minimum of four years' medical study is required. The board finds it difficult, writes Dr. Messum, to decide on the merits of the various diplomas issued in the different American States (is there special wonder?) and asks information on the following points:

1. Are there State universities or colleges whose degrees are recognized as giving the right to practice throughout the whole of the United States of America?

2. Can we obtain a list of universities or colleges which demand a four years' course, and can the approximate date be given when such four years' course became compulsory in such college?

3. Is there a list of the universities and colleges whose degrees are recognized by the medical board of the United States of America?

4. Are there registers of the qualified men in each State, or is there a general register for the whole of the United States of America on which the name of every qualified man can be found?¹¹

Here is the South African republic refusing to admit to practice any physician with less than four years' collegiate medical training, while many States in the Union yet hesitate to establish that minimum. When this confederation has made adequate answer to the voice from the Transvaal it will have accomplished a very essential part of its mission.

A CONDITION OF UNREST.

The fact must be apparent to every one who has given the questions arising out of State licensure much thought, that many of the difficulties which we are meeting, some of which I have considered, arise from the fact that we are in the midst of a period of unrest. The doctors are clamorous, legislators are feverish and students are excited. Nearly everybody having to do with the subject directly or indirectly seems to be uncertain as to opinion and unstable in action. Many appear to be standing on tiptoe all agog, waiting to hail something newer and stranger than that which went before. It is not unlike the excitement that follows upon the discovery of a new bonanza, but a period of quietude will soon follow if this confederation assumes its appropriate place and wisely exercises the functions that properly belong to it. It must begin now to take cognizance of our environment and make suggestions for its betterment.

It is this restless spirit that gives birth to so many incongruous and untimely suggestions. Now, it is a proposition to divide the State examination; then, to create a national examining and licensing board; again, a demand for reciprocity of licensure, and at another time legislatures are appealed to to reduce the barriers to entrance upon the study of medicine, as recently happened in the State of New York. These and other propositions are hurled at us one after another, singly or in groups, with a rapidity that would dismay any but the intrepid, and with an audacity worthy of disciplined ranks. And this before the State boards have fairly formulated their work, or, at any rate, before any tangible results of the system are manifested. But let it be remembered that "thrice is he armed that hath his quarrel just," and so we may take much comfort in the thought that the people, though slow to arouse themselves to reforms, when once they determine on a line of policy that is just and needful, are seldom turned aside until their full purpose is accomplished.

CONCLUSION.

But I detain you too long from the enjoyment of the intellectual feast that awaits you. The recent action of Harvard University in giving notice that a degree will soon be required for an entrance to its medical school,¹² and the statement that the University of Pennsylvania will raise her standard¹³ indicate

that a movement has commenced of a most substantial nature. Though there is a vast field before us in which to labor for the advancement of educational standards there is every reason for encouragement from the support that medical teachers, medical journals, educators and many other people of intelligence are affording us.

This organization ought to be the means of hastening on the work to a considerable degree. An interchange of thoughts and methods through the annual conferences of this body will tend to unify and standardize much of the work that otherwise would be without system or harmony. This body, to borrow the thought of another, ought to act as a kind of professional clearing house,¹⁴ and I trust it will soon come to be so regarded by all interested in educational progress. Let me also suggest that the *Bulletin of the American Academy of Medicine* be made the medium during the intervals of our meetings for an interchange of thought on all matters of interest to the confederation. It has been made, by formal action, the official journal of this body, and its columns are open to all its members. The American Academy of Medicine, and the Association of American Medical Colleges, are to be regarded as our allies in the field in which we labor. It is fitting, therefore, that these three bodies should record their work in the pages of the same magazine, which is a journal devoted especially and exclusively to improvement in medical education.

Finally, let me urge united action by all the friends of medical progress everywhere throughout the land to the end that the education of American physicians may be brought to a standard that shall be high enough at least to make them the peers of their European confrères. The reproach cast upon us through a refusal to recognize our diplomas in Europe can not be overcome until we rise in our might and determine to wage a relentless war against ignorance, which shall not cease until an American State license to practice medicine is recognized as a passport to good professional society in every civilized country in the world.

WAS GOLDSMITH A PHYSICIAN?

Delivered before the Johns Hopkins Hospital Historical Society.

BY JOHN MORRIS, M.D.

BALTIMORE, MD.

The great difficulty in tracing out the history of the medical education of Goldsmith, particularly that portion of it which he is said to have acquired at Leyden and Padua, is due to the fact that no biography of him was written by his contemporaries. It is a remarkable circumstance that the greatest genius of his age, indeed one of the greatest of any age, should not have had a biographer until fifty years after his death, when Prior, his countryman and admirer, favored the world with his most interesting life of Gold-

smith, the material of which was gleaned from many obscure and imperfect sources. This is more remarkable when we remember that he was pronounced the greatest poet of his time by Sir Walter Scott; that he had written the best novel of the century, according to Goethe; the best history in the opinion of Dr. Johnson (no mean critic); essays that were and still remain the charm of every household; a natural history the most delightful and instructive in the English language up to his day; plays that will last all time when those of the 17th and 18th centuries will be forgotten, and still more those of the 19th; biographies charming in diction, purity and simplicity of style—that this man, only equaled in history as a writer by Voltaire, should have been overlooked by his contemporaries and allowed to depend on the sympathy and love of an after-generation for the perpetuation of his memory. Even the place of his birth has been disputed. Four counties claim him as their own.

Septum urbes certant de stirpe insignis Homeri,
Smyrna, Rhodes, Colophon, Salamis, Chios, Argos, Athenæ.

Even Dr. Johnson, in the celebrated epitaph which many of us have seen in Westminster Abbey, places the year of Goldsmith's birth as 1721 when it was actually 1728, and names Elphin as his birthplace, whereas it was Pallas or Pallasmore.

His first teacher was Mrs. Elizabeth Delap, who pronounced him one of the dullest boys ever placed under her charge, in fact, "impenetrably stupid." Dr. Streat says "he was considered by his contemporaries and schoolfellows, with whom he conversed on the subject, as a stupid, heavy blockhead, little better than a fool, whom every one made fun of."

At the age of six he was placed in the hands of Thomas Byrne, the village schoolmaster, a most original character, whom he has immortalized in the *Deserted Village*. This man Byrne had a very chequered career. He believed firmly in all the folklore of his time, fairies, brownies, elves, good people, witches, etc. He was a great authority with the villagers who were amazed by his learning.

"And still they gazed, and still the wonder grew,
That one small head could carry all he knew."

No doubt that Paddy Byrne, as he was familiarly called, left his impress on the life of his pupil and imbued him with that love of wandering and adventure, vagabondage it might be termed, which characterized his career.

At this time he read with great avidity what were termed the "Cottage Classics of Ireland." This collection embraced such stories as the *History of the Irish Rogues and Rapparees*; *Lives of Celebrated Pirates*; *History of Moll Flanders*, of Jack the Bachelor (a notorious smuggler), of Fair Rosamond and Jane Shore, of Donna Rozena, the Spanish Courtesan; the *Life and Adventures of James Freney*, a Famous Irish Robber; *Ovid's Art of Love*, *The Devil and Dr. Faustus*; *Parisinus and Parisinus*; *History of Witches and Ghosts*; *Montelea, Knight of the Oracle*; *Seven Champions of Christendom*; *Mendoza's Art of Boxing*; the only good volumes to be found in the series were several excellent spelling books.¹

¹ The poet in after years, speaking of this time, said: "Happy could so charming an illusion still continue. I find that age and knowledge only contribute to sour our disposition. My present enjoyments may be more refined but they are infinitely less pleasing." The pleasure the best actor gives me can no way compare with that I have received from a country wag who imitated a quaker sermon. The music of the finest singer is dissonance to what I felt when an old dairymaid sung me to

After passing through Paddy Byrne's curriculum, Goldsmith was put under the charge of the Rev. Mr. Griffin, the schoolmaster of Elphin, and entered upon studies of a higher character. He was first intended for mercantile life, but his fond mother thought him a genius. The plans were then changed and he was fitted by Mr. Griffin for the University. His career under this gentleman was not a brilliant one. It was marked by his usual characteristics, indolence, negligence and recklessness. He was afterward removed to the school of the Rev. Patrick Hughes, a classical scholar. Here, strange to say, he made considerable progress in the classics, thus fitting himself in some degree for his mission at the University.

Goldsmith never wished to enter the University, if we may judge by what he says in a letter written to his brother long afterward: "A boy who understands perfectly well Latin, French and the principles of the civil law, and can write a fine hand, has an education that may qualify him for any undertaking."

He entered Trinity College as sizer on June 11, 1745. There are five classes of students in Trinity, a sizer being the lowest, noblemen, noblemen's sons, fellow commoners, pensioners taking precedence. A sizer is compelled to perform menial duties in consideration of getting his commons and tuition free. The indignities and humiliations of such a position no doubt affected Goldsmith's whole character, as well as the brutality of his tutor, Mr. Wilder. Dr. Wilson, who was his fellow student, thus writes: "While he resided in the college he exhibited no specimens of that genius which in his maturer years raised his character so high. Squalid poverty and its concomitants, idleness and dependence, probably checked every aspiring hope and repressed the exhibition of his talents, and the savage brutality that shone so conspicuous in the truly amiable gentleman (Mr. Wilder) who was to rule his studies under the notion of a tutor who was far better calculated to frighten than allure. I well remember, for he was in the class below me, that his tutor examining him in the senior sophomore class, commenced his judgments with a *male* and ended them with *valde bene*. It was a mistake that the good doctor (the tutor) often fell into, to think he was witty when he was simply malicious. Possibly the world is obliged for his (Goldsmith's) works to his idleness and miscarriages in the college, which deprived him of all hope of rising in the church to a curacy, on which he might have comfortably starved to a good old age."

Goldsmith's great love of the classics and hatred of mathematics may have been in a great measure due to his dislike of Dr. Wilder, who was a great mathematician and afterward published several able works upon the subject. Goldsmith said that mathematicians were men of inferior intellect, a sentiment which many persons will accept. Ovid and Horace were his delight, as readily might be supposed from his character and temperament; even Livy and Tacitus, after he managed the difficulties of the latter, became to him charming reading. This was no doubt owing to the descriptions of emotions and events which harmonized with his taste for travel and adventure. For Cicero he had no liking and for this I do not blame him, for Cicero is an author who only has charms for legal and theological prigs.

It is scarcely necessary to dwell on the four years

tears with 'Johnny Armstrong's Last Good Night,' or the 'Cruelty of Barbara Allen.'

college life of Goldsmith. His career at the University was not at all creditable and he got into many difficulties and was at one time about to be expelled. Stunned by the cruel and bitter taunts of his tutor, he determined not only to leave the college, but his native country, and for this purpose he sold his books and clothes and started for Dublin, intending to embark at Cork for America. He loitered about Dublin, spent all his money, and was compelled to return penniless and humiliated to his friends, who by their entreaties secured his reëtrance to the University.

At length he took his final degree as Bachelor of Arts in 1749 and left the scene of all his trials, sorrows and disgrace. There was some difficulty in proving in after years that he had secured this degree, on account of some of the college records having been lost, but Prior, after the greatest amount of laborious research, finally procured sufficient evidence of the fact.

It was then determined by his friends, much to his disgust, that he should prepare for holy orders. This required two years of probation. These two years he spent in absolute idleness. Most of his time was passed with his boon companions at the "Three Jolly Pigeons." His companions at this hostelry are supposed to have been Tony Lumpkins and his associates: "Dick Muggins, the exciseman; Jack Slang, the horse doctor; little Aminidab, that grinds the music box, and Tom Twist, that spins the pewter platter."

At length the two years transpired and Goldsmith appeared before the Bishop of Elphin to apply for ordination. On this occasion he was brilliantly arrayed, in his usual taste, in a pair of scarlet breeches. He was rejected. After this he made a second attempt to sail to America and see the world. He took passage from Cork, but was detained there three weeks by the weather, and the ship sailed in the night without him. Penniless, and after many adventures, he returned again to his friends on an old hack called Fiddle Back, a sorry sight indeed.

It was then determined that he should study law and £50 was advanced by his dear old uncle Contarine for that purpose. He set off for London to enter on his studies at the Temple, but, as was generally his fate, he fell into bad company at Dublin, was beguiled into a gambling house and thus stripped of his £50. After a time his friends brought him back. It was then determined, after a consultation among them, that, inasmuch as he had failed in divinity and law, the one thing left was the profession of medicine. A purse was again made up and in the autumn of 1752 Goldsmith made his appearance in Edinburgh as a medical student. He attended the lectures and attached himself to a medical society composed of students. It is not necessary to dwell upon his habits here. The same old rôle, and Edinburgh was at that time the worst place in the world for a man of his temperament. The tavern was the Areopagus, and as the greater number of Goldsmith's intimates were unfortunately Irish students, we may clearly judge of the character of their pursuits and pastimes.

I will relate an incident which as it has a medical bearing may not be uninteresting. At one of these *séances* (orgies would perhaps be the better word), a dispute arose in regard to ghosts, some of the company contending for the possibility of spirits returning to their former homes. One of the disputants sailed the next day for London, but the vessel had to put back through stress of weather. This was not

known excepting to one of the believers in ghosts who, in concert with the returned student, concocted a trick ("put up a job" is the modern term) to play on the unbelievers. That night at a meeting of the students the discussion was renewed. One of the most active opposers of the ghost theory was asked whether he would doubt ocular demonstration. He still continued his argument. Some kind of hocus-pocus maneuvers were gone through and the student who had sailed for London immediately made his appearance. The doubter fainted, became insane afterward and ended his days in a madhouse. This incident is related by Dr. Farr, who was a fellow-student of Goldsmith.

After spending two winters in Edinburgh in idleness and dissipation Goldsmith prepared to finish his studies on the continent. As usual Uncle Contarine's purse was emptied. He wrote to his uncle as follows: "I intend to visit Paris, where the great Farhein, petite Du Hamel de Monceau instruct their pupils in all the branches of medicine. They speak French and consequently I shall have much the advantage of most of my countrymen as I am perfectly acquainted with that language, and few who leave Ireland are so." This last statement is amusing in the extreme, for all the French Goldsmith knew was what he picked up from the Irish priests in his neighborhood, who were at that time, owing to the penal laws, educated in France. He said himself that when he left Ireland he only took away "his brogue and his blunders," and I am sure that the French that he took with him was a very insignificant quantity. "I shall spend the spring and summer in Paris and the beginning of next winter go to Leyden. The great Gaubinus is still alive there, and 'twill be proper to go, though only to have it said that we have studied in so famous a university." Whilst it would appear that the acquirement of knowledge was the *motif* for his visit to the continent it was in truth a mere pretext to get away for the enjoyment of travel and adventure.

Among the professors at that time at Edinburgh was Moiro, professor of anatomy, whom Goldsmith pronounced an able orator; Plume, professor of chemistry, who, Goldsmith says, understands his business well, but delivers himself so ill that he is but little regarded; Alston, professor of materia medica, speaks much but little to the purpose. The professors of theory and practice, he continues, say nothing but what we may find in books (which he never consulted) and speak in so drowsy and heavy a manner that their hearers are not many degrees in a better state than their patients.

Among his fellow students were men who afterward attained considerable distinction, viz., Dr. Joseph Fenn, Sleight and Mr. Lauchlan Maclean. The Letters of Junius were at one time attributed to Maclean. Another fellow student with whom Goldsmith kept up an intimacy in after life was Dr. William Farr, Fellow of the Royal Society, who had been educated under the eminent Dr. Doddridge; Meade was also, I believe, a fellow student.

It is not necessary to dwell upon the many escapades and troubles that befell Goldsmith on his way to Leyden. He was arrested and put in prison before leaving England: the ship that he proposed to sail in was lost at sea, but he finally arrived safe at Rotterdam, whence he journeyed on foot to Leyden. He writes from here, "Physic is by no means taught so well here as in Edingburgh; and in all Leyden there

are but four British students, owing to all necessities being so extremely dear, and the professors so very lazy (the chemist professor excepted) that we don't much care to come hither." Among the British students mentioned was Dr. Ellis, who afterward became a famous physician, and who always befriended him by loans of money and a great deal of good advice which was not heeded. To eke out his slender resources Goldsmith undertook to teach the Hollanders the English language, but as he did not understand a word of Dutch and had but a smattering of French, picked up from the Irish priests at Ballymahon, he met with indifferent success and soon abandoned the enterprise.

He remained about a year at Leyden, attending the lectures of Gaubius on chemistry, and Albinus on anatomy. I think his attendance at the lectures was merely nominal for the reason that he devoted himself almost entirely to general literature. He obtained no degree at Leyden, according to the statement of all his biographers. Almost penniless he left Leyden to journey to Paris. He started on this romantic journey with one spare shirt, a flute and a single guinea.

"Blessed," says one of his biographers, "with a good constitution, an adventurous spirit, and with that thoughtless, or perhaps, happy disposition which takes no care for to-morrow, he continued his travels for a long time in spite of innumerable privations." Some incidents of this journey may be gleaned from *The Traveler*, and the philosophic vagabond in the Vicar of Wakefield. It is believed that he stopped at Louvain, and Glover, one of his friends, says that Goldsmith obtained the degree of M.B. at this well known university. None of his biographers, however, give credit to this statement.

His journey from Louvain to Paris was characterized by many romantic adventures. His flute was his main reliance, if not his sole support. His performance on this instrument was not highly artistic. He describes it himself:

"How often have I led thy sportive choir,
With tuneless pipe, beside the murmuring Loire!
Where shading elms along the margin grew,
And freshened from the wave the zephyr flew;
And haply, though my harsh touch, faltering, still,
But mock'd all tune and marred the dancer's skill,
Yet would the village praise my wondrous power,
And dance, forgetful of the noontide hour."

At Paris he attended the lectures of Rouelle, a famous chemist of that day. Rouelle was the first to discover the composition of the diamond by submitting it to combustion. Goldsmith claims to have mingled in the best society in Paris, and to have made the acquaintance of Voltaire. In his biography of this distinguished Frenchman, written many years afterward, he gives a most interesting account of a discussion on a literary subject which took place between Voltaire and Fontenelle. This controversy lasted until three o'clock in the morning. There is a great deal of doubt concerning the acquaintance of Goldsmith with Voltaire, and some of his biographers believe it to be purely imaginary.

Goldsmith, leaving Paris, wandered through Germany and Switzerland and we next find him in Geneva. He thus speaks of the Germans: "But let the Germans have their due: if they are often a little dull, no nation alive assumed a more laudable solemnity or better understands all the little decorums of stupidity. Let the discourse of a professor run on never so

heavily, it can not be irksome to his dozing pupils, who frequently lend him their sympathetic nods of approbation. I have sometimes attended their disputes at graduation. On this occasion they often dispense with learned gravity, and seem really all alive. The disputes are managed between the followers of Cartesianism, whose exploded system they call the new philosophy, and those of Aristotle. Though both parties are wrong, they argue with an obstinacy worthy the cause of truth; *Nego, Probo*, and *Dislinguo* grow loud. The disputants grow warm, the moderator can not be heard, the audience take part in the debate, till at last the whole hall buzzes with erroneous philosophy."

At Geneva Goldsmith became tutor to a mongrel English youth, but after traveling some weeks together they quarreled and parted at Marseilles. Again he started on foot in old vagabond way to journey through France, Piedmont, and some of the Italian states and finally reached Padua. On this pilgrimage Goldsmith's flute served but little purpose in procuring him food and lodging, as in that beautiful land every one is a musician. He says, however, that he had acquired another talent, that is skill in disputation, by which he secured a living from day to day. In all the foreign universities and convents there were upon certain days philosophic theses maintained against every disputant, for which if the controversialist managed his argument well, he could claim a gratuity in money, dinner and a bed for one night. Goldsmith was kindly received by the inmates of these universities. "With the members of these universities," said he, "I could converse on topics of literature, and then I always forgot the meanness of my circumstances." This happy custom came down from the middle ages, and obtained even in England up to the time of Henry VIII.

He remained but a few months at Padua and there is no proof at all that he obtained a medical degree at the famous university of that city, a university which many of the greatest men in history had attended and secured degrees, including the renowned Albertus Magnus and the immortal Harvey. The great teacher in Harvey's time was Acquapendente, who taught the doctrine of Sarpi in regard to the office of the valves of the veins. In a life recently published of Fra Paoli Sarpi it is claimed that Harvey got his first views in regard to the circulation from the teachings of Acquapendente.

Leaving Padua, Goldsmith once more turned his face toward England. His wonderful flute, as formerly, supported him during his journey through France and finally, after two years absence, he landed at Dover in the early part of the year 1756. He complains at this time of the difficulties he had to encounter in getting employment, being without friends, recommendations, money, or impudence and, above all, the fact that he was an Irishman. He applied to a country apothecary for a situation, but all the learning of Leyden and Padua could not secure him the place.

His medical career in England I shall dwell on very briefly. After reaching London, then as now, the great *refugium*, he was reduced to many straits. He first secured a position as *usher*. He held this but a short time. In the Vicar of Wakefield he gives an amusing account of the requisites for an usher. "Have you been bred apprentice to the business?" "No." "Then you won't do for a school." "Can you lie three in a bed?" "No." "Then you won't do for

a school." "Can you dress the boys' hair?" "No." "Then you will not do for a school." "Have you a good stomach?" "Yes." "Then you will by no means do for a school." "I have been usher in a boarding-school myself, and may I die of an anodyne necklace, but I had rather be under-turnkey at Newgate. I was up early and late; I was browbeaten by the master, hated for my ugly face by the mistress, worried by the boys." Goldsmith said afterward speaking of this time: "After all the fatigues of the day, the poor usher of an academy is obliged to sleep in the same bed with a Frenchman, a teacher of that language to the boys, who disturbs him every night an hour, perhaps, in papering and filleting his hair, and stinks worse than a carrion with his rancid pomatums when he lays his head beside him on the bolster."

After vacating the place of usher he was employed by a chemist named Jacob, who took compassion on his destitute condition. Here he remained for a few months. Hearing that his old Edinburgh friend, Dr. Sleigh, was in London, he called on him and was received with the greatest kindness, though Dr. S. did not recognize him at first on account of the shabbiness of his appearance. Through the friendship of Dr. Sleigh and other friends whom he found in London, Goldsmith was able to establish himself as physician in a very humble way, in Bankside, Southwark. He practiced here for a very short time. The poor flocked to him in numbers, but the rich gave him an extremely wide berth. He lacked the polish, the address, the *savoir faire* necessary to secure their favor. At that time in England, nor for many years afterward, as there were no registration laws in existence, a medical degree was not necessary. Dr. Farr gives a very amusing account of his appearance as a physician, dressed in a professional suit of black, to which added a wig and the gold headed cane, indispensable in those days. The coat was a second-hand one of rusty velvet with a patch on the left breast. Goldsmith always pressed his three-cornered hat on this patch to hide it, and the efforts of his poor patients to relieve him of his hat and his efforts to retain it were very amusing.

He soon abandoned the practice of physic and took charge of a classical school in Surrey, kept by the Rev. Dr. John Milner. Leaving this school he applied for a place as surgeon's mate in the East India service, no doubt influenced by the example of Grainger and Smollett, who had served in the navy as surgeons, but to the utter horror of his friends, he failed to pass his examination at Surgeon's Hall. From the records of the College of Surgeons it appears that Goldsmith underwent his examination on Dec. 21, 1758.

I now come to the last episode in Goldsmith's medical career. He had written many essays and sketches and a great variety of hackney work, which gave him only bread and a "lodging next the sky," when *The Traveler* appeared, the first publication which bore his name, and which at once gave him a place among the first literary men of the time. "I was glad," said Sir Joshua, "to hear Chales Fox say it was one of the finest poems in the English language." "Why were you glad?" rejoined Langton: "you surely had no doubt of this before." "No," interposed Johnson, decisively; "the merit of *The Traveler* is so well established that Mr. Fox's praise can not augment it, nor his censure diminish it."

As his fame augmented, under the advice of his friends, Goldsmith attempted to secure a more regular and certain support by resuming the medical profession. He started out in great style; hired a man servant, purchased a new wardrobe at much expense; and procured the professional wig and cane, purple silk small clothes, and a scarlet roquelaure buttoned to the chin; a not unfitting garb for a medical man of that period, though rather unsuited to our own day.

He did not practice very long. A lady of that time describes him as strutting into the apartments of his patients swaying his three cornered hat in one hand and his cane in the other, and assuming an air of gravity suited to the solemnity of his wig. The last scene I quote from Irving, who, in turn, quoted from Prior, and is as follows: "He soon, however, grew tired and impatient of the duties and restraints of his profession; his practice was chiefly among his friends, and the fees were not sufficient for his maintenance; he was disgusted with attendance on sick-chambers and capricious patients, and looked back with longing eyes to his tavern haunts and broad convivial meetings, from which the dignity and duties of his medical calling restrained him. At length on prescribing to a lady of his acquaintance who, to use a hackneyed phrase, 'rejoiced' in the aristocratic name of Sidebotham, a warm dispute arose between him and the apothecary as to the quantity of medicine to be administered. The doctor stood up for the rights and dignities of his profession, and resented the interference of the compounder of drugs. His rights and dignities, however, were disregarded; his wig and cane and scarlet roquelaure were of no avail; Mrs. Sidebotham sided with the hero of the pestle and mortar; and Goldsmith flung out of the house in a passion. 'I am determined,' said he to Topham Beauclerc, 'to leave off prescribing for friends.' 'Do so, my dear doctor,' was the reply; 'whenever you undertake to kill, let it be only your enemies.'"

Finis coronat opus!—It would be to me the highest pleasure could I truthfully claim this great man, for so Dr. Johnson terms him as a member of our profession; but after very faithful research, with an honest hope that I could discover proofs of his having obtained a medical degree, I am constrained to declare that his education did not fit him for a professional life or that any university, under the most lax conditions, could have granted him a degree; therefore, the verdict must be in Scotch fashion, "not proven."

ORIGINAL ARTICLES.

ONCE MORE ON ANTITOXIN.

BY CARL STRUEH, M.D.

CHICAGO.

In the issue of the *JOURNAL* of January 25 of the current year, there appeared a short article of mine entitled "Criticism of the Antitoxin Treatment from a Different Standpoint," in regard to which I received a very interesting letter from my friend Dr. X. at St. P., in which letter the doctor opposes in a most instructive manner some remarks which I have made in my article. As Dr. X. apparently represents the opinion of the majority of the advocates of the antitoxin treatment, I am very much indebted to him for giving me the permission to discuss the contents of his letter in the *JOURNAL*.

Dr. X., in short, says: 1, that the statistics we have, at the present time, command of are made from such cases which were proven to be diphtheria from a bacteriologic examination, and that these statistics in comparison with those we had under the old treatment are so much in favor of the antitoxin that we must ascribe the lower mortality to the latter; 2, that he believes in the efficacy of the drugs for local and general treatment, so that he does not think the exclusion of the drug treatment is the cause of the lower mortality; 3, that he has seen most surprising changes in the course of the disease, which changes he could only ascribe to the serum treatment; 4, that he has never seen any ill effects from the antitoxin; 5, that he saw some recoveries from croup under the serum treatment without intubation or tracheotomy having been required; 6, that he does not agree with my saying that "it is not the rule that from a child being sick with diphtheria the majority of the family becomes infected," and he believes that by immunization many a child can be protected against diphtheria; 7, that he believes we will have a serotherapy for typhoid in the future as we have for diphtheria now.

I am well aware that it is not an easy task to successfully contradict these statements. Still we will see what can be said against them.

In regard to the first statement I fully admit that we possess quite a number of statistics which give very much credit to the antitoxin. I undertook to inquire about the death rate with the serum treatment from the health commissioners of different cities in the United States, and received a great number of statistics, some of which show the following figures:

NEW YORK CITY.

Diphtheria and croup; case fatality, first, second and third quarters of each year, 1891 to 1895 inclusive:

Year.	Cases.	Deaths.	Percentage.
1891	3,686	1,349	36.59
1892	4,158	1,540	37.04
1893	4,721	1,763	37.34
1894	7,446	2,284	30.67
1891 4	20,011	6,936	34.66
1895	7,921	1,543	19.43

Reduction in death rate first second and third quarters of 1895, as compared with average death rate for corresponding periods of previous four years, 16.23 per cent., or a reduction of 43.94 per cent. of the previous rate.

Case fatality, fourth quarters of 1891 to 1893 inclusive, and 1895.

Year.	Cases.	Deaths.	Percentage.
1891	1,678	621	37.01
1892	1,126	566	50.26
1893	2,400	795	33.13
1891 3	5,204	1,982	40.13
1895	2,465	433	17.52

Reduction of death rate, fourth quarter of 1895, as compared with average death rate for corresponding periods of the years 1891-1893 is 22.61 per cent. or a reduction of 56.31 per cent. of the previous rate.

Table showing case fatality in diphtheria and croup in New York city for the period Jan. 1, 1895, to Oct. 6, 1895 (during which antitoxin was employed), as compared with the period between Jan. 1, 1891, and Oct. 6, 1891. The figures denote the percentage in periods of four weeks.

	1894	1895	1896
January 27	43.30	25.77	
February 24	39.43	24.43	
March 24	34.20	20.31	
April 21	36.00	20.68	
May 19	35.96	20.76	
June 16	30.50	20.58	
July 14	27.06	12.23	
August 11	30.51	19.63	
September 8	33.15	23.74	
October 6	29.76	18.93	
November 2		16.66	
November 30		21.02	
December 28		16.32	
January 25			15.97
Total cases	6,876	7,475	3,373
Total deaths	2,337	1,582	580
Average case fatality	33.93	21.16	

INDIANAPOLIS.

Report for the seven months ending Jan. 31, 1896.
Before using antitoxin:

1895	Cases.	Deaths.
July	4	3
August	26	6
September	70	27
October	132	25
Total	232	61

Showing the per cent. of deaths to the number of cases to be 26.29 in a hundred.

After using antitoxin:

	Cases.	Deaths.
November, 1895	93	10
December, 1895	65	12
January, 1896	44	5
Total	202	27

Showing a death rate of 13.36 per cent. to the hundred cases.

ST. LOUIS.

In the first six months of 1895 there were reported to the health office 645 cases of diphtheria of which 164 proved fatal, which was a mortality of 25.4 per cent. In the last six months of 1895 there were reported 2,233 cases, of which 355 proved fatal, which was a mortality of 15.8 per cent. The record of diphtheria in St. Louis for the past ten years is as follows:

Year.	Cases.	Deaths.	Percentage.
1886	2,826	719	25.44
1887	3,108	927	29.82
1888	1,658	564	34.01
1889	1,240	345	27.82
1890	667	185	27.73
1891	771	249	32.29
1892	671	208	31.00
1893	613	242	39.47
1894	751	238	31.69
1895	2,878	519	18.03
Total	15,186	4,196	

MINNEAPOLIS.

The total number of cases reported in 1895 was 569, with 114 deaths (mortality 20 per cent.). In 131 cases antitoxin was used, with 11 deaths (mortality 8.4 per cent.). The previous year the total number of cases was 191, with 54 deaths (mortality 28.2 per cent.).

Statistics similarly favorable are reported from a large number of places where antitoxin has been used. And yet I doubt that these reports, even if they were all unobjectionable as such, are appropriate evidence already for deciding definitely, as a great number of physicians do, upon a question of such comprehensive

signification. In the first place, we must not forget that statistics as such are most unreliable, because every individual case differs from others so that we always compare unequal values. Furthermore, endemic, epidemic and other circumstances cut such a figure that it at the least seems very risky to decide upon the value of a new remedy from the experience of one or a few years. In the Children's Hospital at Basel, for instance, the mortality in 1876 was 34 per cent., in 1886 only 6 per cent. Had they used any new remedy during the latter year, the decrease in the mortality would undoubtedly have been ascribed to the new treatment.

How much the statistic results of the serumtherapy must depend upon other influences we learn from the difference in the mortality, which various observers claim, as is shown in the following percentage figures:

Stockholm 2, Holland 7, Minneapolis 8.4, Chicago, 8.93, Paris Children's Hospital (Lebreton and Magdelaine, 330 cases) 12, Rumpf 12, Ganghofer 12.72, Baginsky 13, France 13, Indianapolis 13, Bokai 14, Washburn 14, Hungary 14.3, Italy 14.4, Soltmann 14.6, Germany 14.8, Austria 14.9, St. Louis 15, Berlin 17.4, New York City 19, Constantini 22, Vienna 22.8, Kossel 23, England 23, Widerhofer 24, Roux, Martin, Chaillou 26; Milwaukee 27, Waingen 28, Körte in grave cases 58.2, medium 29.8, light 3.3, Gnädinger 40, Trieste (252 cases) 63.

So we see that the mortality ranges from 2 per cent. to 63 per cent., a difference hardly possible if the treatment were a "specific." There are other reports from which we learn that the difference in the mortality before and after the use of antitoxin does not at all give proof of the value of the serum. The Friedrichshain statistics, for instance, show the following mortality:

1888, 32 per cent.; 1889, 34 per cent.; 1891, 1892, 1893, 38 per cent.; 1894 (February to November, serum period), 33 per cent.

So in 1888, when no antitoxin was used, the mortality was lower than during the serum period in 1894.

I note the same feature in the Milwaukee statistics. In 1891 the death rate is lower than during the serum period in 1895.

MILWAUKEE.

Year.	Cases.	Deaths.	Per-centage.
1890	827	241	29.13
1891	1,480	400	26.79
1892	1,193	400	33.53
1893	620	209	33.71
1894	436	175	40.13
Total.	4,565	1,425	31.19
February, 1895 ¹	433	117	27.02

Very important are the statistics which show the actual number of deaths from diphtheria and croup in the city of Berlin, viz.:

1881, 1,953; 1882, 1,913; 1883 (severe epidemic), 2,561; 1884 (severe epidemic), 2,446; 1885, 1,802; 1886, 1,535; 1887, 1,304; 1888, 1,070; 1889, 1,252; 1890, 1,549; 1891, 1,057; 1892, 1,405; 1893 (serum period), 1,643; 1894 (serum period), 1,430.

This table shows that the antitoxin did not cause any decrease in the actual number of deaths from diphtheria whatever, even allowing for the increase in population.

There are also reports which show an equal or even lower death rate by the use of other treatments than is claimed for the antitoxin treatment. So in Basel the average mortality in 4,479 cases which were treated during 17 years, was 12.6 per cent.

Dr. S. Schwarz, of Constantinople, recommends treating diphtheria by insufflations of sozodol-sodium and

flowers of sulphur, besides giving for internal use chlorate of potassium (15.22 gr. : 3vi, a tablespoonful every hour) and ext. of nux vomica (2 to 3 times daily) right from the beginning of the disease in order to prevent post-diphtheritic paralysis. Under this treatment he claims to have a mortality of 8 to 10 per cent. and only 2 to 3 per cent. (!) if the cases comes under treatment at an early stage. (*Wiener medicinische Wochenschrift*, 1895, No. 43.) I should think that without this nefarious treatment the death rate would have been considerably lower.

Dr. N. Rosenthal, of Berlin, reports 271 cases which were treated (locally and generally) with sol. of sesquichlorid of iron, a mortality of 8.2 per cent. resulting. (*Therapeutische Monatshefte*, 1895, No. 11.) On the other hand we possess reports showing an increased mortality under the serum treatment. The *Lancet* of Oct. 26, 1895, states that "the mortality from diphtheria in London was more than 40 per cent. in excess of the corrected average for the fortieth week of the last decennial period," in spite of the antitoxin. We also must consider that those statistics which are so much in favor of the serum treatment, are not all unobjectionable. In regard to the statistics of Behring, the main representative of the serum-therapy, for instance, I refer to an article, Serum-therapy and Statistics by Dr. A. Gottstein, Berlin, which appeared in the *Therapeutische Monatshefte*, 1895, No. 11, and in which Behring's statistics is criticized in a very illucidating way by Gottstein presenting authentic figures which were furnished by the Royal Health Department of Berlin, and which relate to all Berlin hospitals and to all cases which were reported by local physicians, so that these figures represent a collective statistic of all Berlin. According to Gottstein the lower mortality must in a great measure be ascribed to the fact that since the introduction of the serum-therapy almost twice as many cases were reported as before, so that Behring does not go by the real number of cases which occurred, but by the number reported. Since 1884 there is existing in Berlin an ordinance making it obligatory for physicians to report diphtheria cases, and in 1887 disinfection was made compulsory. Everybody who knows to what inconveniences the general practitioner subjects his patients and himself in complying with these two ordinances, will understand that perhaps the majority of the physicians ceased to report all of their cases, that in other words the number of reports decreased.

In 1894, two Berlin physicians were indicted for not having reported diphtheria, and the state's attorney motioned for punishment by imprisonment, a circumstance which caused a rapid increase of the reports. Behring's own table shows this fact. There were reported:

	1st Quarter.	2d Quarter.	3d Quarter.	4th Quarter.
1889	978	945	1,075	1,243
1890	1,120	1,019	1,136	1,237
1891	830	763	763	1,086
1892	879	822	875	1,267
1893	1,027	952	1,107	1,275
1894	1,114	1,085	1,058	2,028

So the fourth quarter of the year 1894 shows almost a duplication of the number of cases which were reported. Or does Behring believe that twice as many cases occurred? "If he does," says Gottstein, "we can claim with the same right that the introduction of the serum-therapy was the cause of the increase of diphtheria."

¹ The month in which antitoxin commenced to be used in Milwaukee.

If, however, twice as many cases were reported as before, it is not surprising that the death rate decreased for the figures undoubtedly include many mild cases which previously were not reported.

A statistic which, it seems to me, does not carry much weight, is the one which emanates from our Chicago Health Department and which I find reported in the periodical *The Clinique*, 1895, February 15, No. 11. It is stated in this statistic that since the introduction of the serum-therapy the mortality has decreased from about 52 per cent. to less than 9 per cent., a change which we should all welcome with delight were it not for the fact that the compilers of this report compared a statistic of 1,047 cases treated with antitoxin to one of only 61 cases treated without it. Such a report is absolutely worthless, for the reason that comparative statistics should always relate to an almost equal number of cases. Besides the report fails to enlighten us as to what (drug) treatment was employed in the sixty-one cases.

I was very much surprised when in a Chicago daily paper I read an article which was written in commendation of the serum treatment and in which all the figures favorable to antitoxin were given as I find them recorded by the health department, that no mention at all was made of those sixty-one cases to which the 52 per cent. relate. The statistic as I find it in *The Clinique* is as follows:

Total number of cases of diphtheria visited	1,221
At request of attending physician	1,169
Charity patients (no physician in attendance)	52
Total number found convalescent on arrival	63
Total number found dead on arrival	50
All other cases	1,108
Total number suffering from diphtheria	1,108
Total number treated with antitoxin	1,047
Total number in which antitoxin was not used	61
Total number recovered under antitoxin treatment	961
Total number died under antitoxin treatment	86
Death rate under antitoxin treatment 8.93 per cent.	
Total number in which antitoxin was not used	61
Total number of these known to have died	32
Death rate when antitoxin was not used 52.46 per cent.	

A statistic similar to that of Chicago was some time ago reported from Boston, where the mortality was said to have decreased from about 50 to 16 per cent. the latter relating to sixty-nine cases of which eleven died, quite a good percentage for a "specific." If I should lose every sixth patient I would hardly feel as though I had a specific. From the few statistics I have cited as examples, we see that they are so contradictory, objectionable and depending upon other influences that we certainly can not yet rely upon them very much. We must also consider that when a new remedy has once gained favor, in the first flood of enthusiasm those practitioners having favorable results are always more anxious to report their cases than those having unfavorable ones. And yet one of the latter amounts to more than ten of the former, because it shows the limits of the efficacy of the treatment. Even those unfavorable reports already existing are not sufficiently considered by the antitoxin enthused physicians. We must, therefore, extend our observations over a greater length of time and wait for other epidemics, before we can form a definite opinion, as far as the statistics are concerned, if we insist on laying so much weight on them.

I personally believe that the mortality has decreased under the antitoxin treatment, but I largely ascribe this decrease to the exclusion of the drug treatment,

² "Not used" either because the case was hopeless when seen (?), or the administrator feared the result of its use—as, for example, on the fourth day or later, or because the family or the attending physician changed attitude after calling on the department and refused its use. I should not think they would declare a case hopeless until they used their "specific," especially if it is, as they claim, harmless.

as also good results were obtained in the tuberculin treatment after creosote had been excluded.

The report from the Kaiser and Kaiserin Hospital at Berlin seems to support this assertion. "The average mortality in this hospital was in the neighborhood of 50 per cent. before the use of antitoxin, but upon its introduction the death rate was reduced to below 10 per cent. Then during two months (July and August) the supply of serum having failed, the death rate rose to the former general average, again to fall to the low rate upon the renewal of the antitoxin treatment."

This report deserves consideration in so far as we can exclude endemic conditions as being the cause of the decrease of the death rate. It would, however, be very interesting to know what local and general treatment they used before the introduction of the antitoxin treatment and at the time, when the supply of serum failed. They certainly did not leave the cases without any treatment. If it was the old drug treatment, we can easily explain the fluctuation in the mortality. Even Virchow who was made an advocate of the serum therapy by these "brutal figures," does not seem to have taken into consideration the effect of the interim treatment. It seems to me that the average practitioner does not sufficiently consider the harmfulness of the drug treatment, for we often hear a physician say that he used no other treatment besides the antitoxin and that he obtained splendid results, which, therefore, in his opinion could only be ascribed to the serum. I think quite differently; just because he had not used any other treatment, he had such good results. Again, there are physicians who use antitoxin with their entire former treatment and claim to have obtained better results than before. But this does not prove much either, as apparent good results can be obtained even by a harmful treatment, if the endemic, epidemic and other conditions are favorable, as we see, for instance, from the report of Dr. Schwarz to which I have previously referred. Still I find as a rule that the drug treatment is either entirely excluded or applied in a modified form, when antitoxin is being used. This brings us to statement No. 2 concerning the drug treatment. First I wish to say a few words in regard to the local treatment which is mainly based upon the principle of antiseptics and which is carried out by the following five manipulations: Gargling, spraying, insufflating, swabbing and cauterizing. Now, supposed, but not admitted, that the bacilli diphtheriae were the main part in the disease, and supposed that these bacilli were not burrowed in the mucous membrane, but were located right upon the diphtheritic membrane and could easily be reached by our manipulations, I do not understand what effect these manipulations could have. We know, and this has been proven by experiments, that a bacillus must be exposed to an antiseptic solution of a certain concentration for a certain length of time in order to be destroyed. If the antiseptic solution is not of the necessary strength or if the bacillus is not exposed to the antiseptic for the necessary length of time, our efforts toward destroying the bacillus will be futile. I refer to Sternberg's manual of bacteriology (1893), in which he gives extensive tables of the effects of different antiseptic solutions upon the various bacilli.

We must also consider that a far stronger solution than is required to kill bacilli will be necessary to destroy the spores. We must also consider that in presence of organic material in association with bacte-

ria the disinfectant can be neutralized before the living bacteria are destroyed. For instance, the cholera bacillus in bouillon is destroyed in one-half hour by a solution of HgCl 1 to 6,000, while in blood serum 1 to 800 was required to destroy it in the same time. These facts make our local treatment by antiseptics absolutely worthless and teach us that our raid on the bacilli by these means is all in vain. As far as gargling, spraying and insufflating are concerned I think it impossible to reach the bacilli by these manipulations; even if it were possible the effect of the antiseptic would be of too short a duration to destroy the germ. Still I use gargling and spraying (merely with pure water) not to affect the bacilli but only for cleansing purposes and as a tonic to stimulate the circulation in the fauces. The other two manipulations, swabbing and cauterizing with antiseptics, astringents, etc., oppose the first law in the treatment of acute diseases, viz., to give absolute rest to the diseased organ. Instead of doing so we keep up a continual irritation and congestion to the locus morbi. Furthermore I think it entirely wrong to remove the diphtheritic membrane which is only the local manifestation of general toxemia. That the membrane is an inseparable factor of the process of the disease, although there is no satisfactory explanation for its existence, we see from the fact that as long as the fever and the general symptoms exist, it quickly returns when removed, while after their disappearance the dissolution of the membrane quickly follows. So it appears to me that our local treatment as such is merely illusory and valueless; it is based upon theoretical principles which are derived from experiments on bacterial cultures and which can never be carried out in practice. But the local treatment is not only worthless in itself, but very harmful otherwise. I have already mentioned the harm done by the continual irritation and congestion caused by swabbing and cauterizing, the removal of the membrane and the destroying of the tissue. Furthermore we must consider that a part of the applied solution is always swallowed and absorbed into the system. And will we say that these drugs after having been absorbed do not cause toxic effects before we can ascertain these from outward appearances? But even if the drugs did not produce any direct toxic effects, they would disturb the natural healing process which represents those complex symptoms we generally call disease. They must be eliminated from our system, and this elimination depends in the last instance upon the vital energy which at the same time is engaged in overcoming the disease and in eliminating the products of the same. And it depends upon the severity of the infection and the amount of vital power the body possesses, whether the patient recovers in spite of the two-fold demand or if he succumbs, because his vital energy was not sufficient to cope with both disease and drugs. I need not say that I think the internal medication with antiseptics such as chlorate of potassium and the like just as injurious and illusory as the local treatment, for we will never succeed in making the blood an antiseptic solution to kill the bacillus or its products without destroying the blood itself. As great as the discovery of external antisepsis is, there will never be an internal antiseptic, and the sooner we entertain this idea, the better for ourselves and our patients. Why I discredit those other drugs we use for internal medication, such as sesquichlorid of iron, tincture of iodine and others, I will explain more elab-

orately in a future article in which I will state my position concerning the drug treatment in general.

I still maintain that the drug treatment in diphtheria is merely imaginary and only produces ill effects which undoubtedly have a great influence upon the mortality and the course of the disease. And I do not see why the exclusion, even if only partial, of this treatment shall not give better results than we obtained before. The better results with the present treatment of typhoid for instance, are also not due exclusively to the hydropathic treatment, but in a great measure to the exclusion of the drug treatment.

As long as no extensive investigations have been made into the combined drug and antitoxin treatment of diphtheria, my assertion that the exclusion of drugs is partially accountable for the better results, is not contradicted. Whoever has had sufficient experience with physiologic therapy, will not at all be surprised at the lower mortality which is claimed for the antitoxin after excluding the drugs. He will only be surprised that not more patients died from diphtheria under the old drug poisoning, a treatment which evinced the wonderful capacity the vital power possesses and which showed how much a human being can endure.

In regard to the third statement I do not doubt a moment that many physicians have seen very favorable changes in the course of the disease under the antitoxin treatment, and I believe that such favorable changes lead more physicians to become followers of the antitoxin treatment than the statistics do. But the question is: Are these changes, even could we exclude endemic and epidemic conditions, to be ascribed exclusively to the serum? If we leave nature alone and do not disturb her wise provisions by applying drugs, the good results of which are merely imaginary and which only manifest toxic effects upon the system, we can see many most remarkable changes in the course of the disease, changes which we formerly made impossible by our drug treatment, and which we therefore can accomplish more readily by substituting the less harmful antitoxin.

It is surprising to note what great effect any such unexpected favorable change has upon the medical attendant. I know physicians who were opposed to the serum treatment, but who became most enthusiastic promoters of it, having injected antitoxin in but one or two cases in which they could observe some improvement afterward. If, however, a physician once believes in the efficacy of the serum, he will meet with enough cases in which he can find some advantageous changes, such as decrease in temperature, improved general condition, more rapid dissolution of the membrane, and so on, which he can ascribe to it. Any other less harmful treatment, if used in every acute disease of which fever is a pronounced symptom, would show the same efficaciousness as the serum treatment for diphtheria does to-day.

It would be a thousand times better to pay more attention to those cases in which the antitoxin failed to succeed than to be so much enthused over those showing some good results which are merely incidental in many instances. We can not sustain the infallibility of the serum-therapy in those cases which terminate in death, by saying that death was due to a mixed infection, or that the cases did not come under treatment early enough. The latter excuse, it appears to me, is made too often, and not always in a very logical way. If we inject antitoxin into a child who

perhaps was sick for four or five days, and this child dies, the treatment came too late, while if it recovers we are surprised at the wonderful efficacy of the remedy. I think this is a very illogic way of reasoning. If no fatally ending case injected on the fourth or fifth day proves anything against the antitoxin, no case which recovers, under the same conditions, is proof of the efficacy of the remedy. Beside, it is not at all proven that the antitoxin is an almost sure cure when injected the first day, as some enthusiasts claim. We can corroborate this by numerous reports, for instance: Dr. J. Winters, in the *New York Medical Journal* of Feb. 15, 1896, states that in the Willard Parker Hospital, in 1895, they injected antitoxin on the first day of the disease into 108 children with a mortality of 10.09 per cent.

Furthermore, most of what has been claimed for the antitoxin as, for instance, decrease in temperature, improvement in the general condition, more rapid dissolution of the membrane, and so on, has already been abandoned. I refer again to the report of Dr. Winters, stating that in the Willard Parker Hospital in April, 1895, it was left to the patients, respectively their parents, to decide whether antitoxin should be used or not. Those cases which were not treated with serum proved to take just as good a course, if not a better one, as those in which antitoxin was used. A similar report is made by Prof. Soerensen of Copenhagen (*Therapeutische Monatshefte*, March, 1896).

As far as the fourth statement is concerned, I consider the serum-therapy less harmful than the former drug treatment; still its employment does not seem to be altogether devoid of danger. I only wish to call attention to the very valuable investigations of Dr. James Ewing, who found that the antitoxin caused a diminution of the red blood corpuscles and extensive changes in the leucocytes, and he concludes that these changes are likely to lead to obstructions in the capillary circulation, to changes in the kidneys, to necrotic foci in the liver, to pneumonia areas in the lungs, to obstructions of the cerebral circulation and possibly to convulsions.

In regard to the fifth statement I doubt whether our short experience of only two years is sufficient to decide the value of the serum treatment in membranous croup, as the type of laryngeal diphtheria varies too much. In some epidemics almost every case of croup ends in recovery, while in others most of the cases terminate in death. A severe epidemic may teach us quite different from what we believe to-day. That the praise of antitoxin, as far as its use in croup is concerned, is not so unanimous as is claimed, we see from numerous reports. Vierordt, for instance, claims a mortality of 40 per cent. under the serum treatment.

Beside, it is difficult to understand what effect the antitoxin should have in a case of diphtheria in which the general symptoms scarcely attract our attention and in which the localization of the membrane and the mechanical occlusion of the glottis are the only danger. And also I do not understand why the antitoxin should be timely enough in croup, a diphtheria which perhaps existed four or five days or longer, while in other cases we require the antitoxin to be injected on the first or second day in order to be of benefit to the patient. By the way, I believe there are quite a number of cases diagnosed as membranous croup which in fact are but catarrhal croup, because it usually is impossible to make a laryngoscopic exam-

ination in a child. Even if the patient shows diphtheritic membranes on the tonsils a croup can be spasmodic. I lately was called to a 12 year old boy who showed a slight rise in temperature, severe general symptoms, swelling of the maxillary glands, a small membranous spot on the left tonsil and an "exquisite" croupy cough. The parents requested me to use antitoxin, which I declined. I made a laryngoscopic examination and convinced myself that the boy had no diphtheritic but only catarrhal croup. Had the case concerned a younger child in which a laryngoscopic examination had been impossible, and had I used antitoxin, I would have taken the case to be membranous croup and would have ascribed the recovery to the influence of the serum. But even if a physician had the opportunity to employ the antitoxin in a large number of cases of croup during a longer period and in different epidemics, I would not summarily ascribe his better results to the serum, unless I would know the kind of treatment he formerly employed and now excludes under the serum treatment.

I do not see why the dissolution of the membrane in the larynx, which is only a part of the whole healing process, should not be benefited by the exclusion of the drugs just as much as the dissolution of the membrane in the pharynx does.

I finally wish to call attention to the report of Bertin (*Gazette médicale de Nantes*, 1895, No. 4), who used plain horse serum in three cases of membranous croup, all recovering which leads me to believe that antitoxin is not a specific. These cases were as follows: 1. Five year old girl. Diphtheria of pharynx; membranous croup; swelling of the maxillary glands; Löffler bacillus found; 20 c.cm. of not immunized horse serum injected on the third day of the disease. Rapid improvement. On the sixth day all symptoms have disappeared. On the ninth day severe urticaria over the whole body which heals gradually. 2. Nineteen year old girl. Diphtheria of pharynx; membranous croup; swelling of the maxillary glands; Löffler bacillus found. On the second day 20 c.cm. of not immunized horse serum injected. On the following day peeling off of large pieces of the membrane. Urticaria and alarming general symptoms. Complete recovery twenty-two days after the onset of the disease. 3. Four year old boy. Croup and symptoms of suffocation; Löffler bacillus found. In the evening of the second day 16 c.cm. of not immunized horse serum injected. Great improvement the following day. Complete recovery in the course of four days. Urticaria after another week.

As to the sixth statement, I can only say that Dr. X.'s experience is different from mine. I do not say, of course, that there are instances in which most of the members of a family get infected from a case of diphtheria. But looking over my experience, and I judge from this only, I must say that extensive contagion occurred but in the minority of my cases. To show that I am not isolated in my opinion I wish to call attention to a very instructive treatise (Bacteriological Investigations of Diphtheria in the United States) by Dr. Wm. Welch, Professor of Pathology at the Johns Hopkins University, which appeared in the *American Journal of the Medical Sciences*, October, 1894. Welch found in a group of 113 cases of pseudo-diphtheria (which differs from true diphtheria only by absence of the Löffler bacillus) occurring in 100 different families, that only in nine families the

disease affected more than one member, and in a group of 70 cases of true diphtheria occurring in 50 different families, in only 13 families was more than one member affected.

The question whether the immunizations have such a great prophylactic value as is claimed, is, it seems to me, not yet settled. Hilbert, who favors the prophylactic use of antitoxin, states that in 64 children whom he immunized, he saw "but" 7 infections, which equals 11 per cent. To judge from my own experience I hardly think that in more than 11 per cent. of my cases contagion took place—without immunization. But even if the antitoxin had an immunizing effect, this effect would be of short duration only and might do more harm than good. It does not appear to me that the large dose of carbolic acid injected with the serum, should be so indifferent. It also seems very peculiar to think that an agent which, like the antitoxin, is said to possess the power of neutralizing such a pernicious poison as the toxins of diphtheria are, should be so harmless.

Concerning the seventh and last statement, I firmly believe that for typhoid we will never have a serum-therapy which will amount to very much, because typhoid runs a more regular course than diphtheria does, so that we do not come in contact with so many unexpected favorable changes as we do in the latter disease. Still, very industrious efforts have been and are being made to discover an antitoxin for typhoid; I only refer to Fränkel, who has largely experimented for this purpose. Lately Dr. Klemperer of Strassburg thinks he has discovered an antitoxin against typhoid and has made experiments with it on dogs. He even employed it on five patients, and is of the opinion that he obtained a good result in so far as the disease took a mild course (*Berliner Medizinische Wochenschrift*, 1895, No. 28). But in spite of these industrious investigations, I do not believe that there will ever be a serum-therapy for typhoid which will be superior to the hydropathic treatment, as far as the mortality, the course of the disease and the *restitutio ad integrum* are concerned.

What I have said in the foregoing lines is, of course, only my personal view of the matter. If I should be mistaken in every or any part, I would be thankful to have some one refute my assertions. The subject is of such great importance that it ought to be discussed from every possible standpoint, and whosoever is opposed to the serum treatment, no matter what his reasons may be, should come forward and proclaim himself, though he may not receive the attention paid those who boast of the wonderful efficacy of the new remedy, an efficacy for which they have no more scientific proof than they have for the efficacy of most of the drugs. What do we know of the antitoxin and its action? Nothing. Nobody knows what antitoxin is. For what does it matter, if we are told that "the antitoxins are products of bacteria formed in the blood of the animal body, though we do not know the process of the formation of these antitoxins and their chemie nature," or if, as Roux believes, "the antitoxins are produced by cells, but not by the white blood corpuscles." Similar philosophic explanations are given in regard to the action of the antitoxin, but of what benefit is it if, as Roux believes, "the injection of antitoxin will not cause neutralization of the bacterial poison, but a rapid process of immunizing." Another explanation, for which we hardly can give any positive proof, is that of Pohl. Pohl says "the

greatest part of the albumin in the alimentary canal is transformed into lymph cells inside the lymphatic tissues of the intestinal wall; that means it is organized into a living form of albumin. Those leucocytes which have been so formed in the intestinal walls are thrown into the circulation and perish inside of the circulatory channels and in the tissues. So that a few hours after each meal active albumin will be present in solution in the blood. If now we inject into rabbits or sheep pure cultures of erysipelas, for instance, the streptococci will perish in the animal body in great numbers, and it is very probable that the albuminous part of their bodies will combine with the active blood albumin, the immune protein, and form immune proteidins which kills anthrax bacilli."

Others claim that the antitoxin causes an increased leucocytosis, but this explanation is also objectionable. We know that leucocytosis in an acute disease sets in only after the acute stage is passed, a fact which proves with undoubted certainty that it dare not set in before. If we, therefore, should succeed in producing it at an earlier stage, we would disturb the healing process in which every single cell has its definite place and time and function. Again, others explain the effects of the antitoxin by the amount of carbolic acid injected with the serum.

It is also claimed that there is nothing specific in the diphtheria antitoxin, but that it only produces a stronger reaction. This idea seems to be supported by Bertin, who had good results with non-immunized horse serum, and by Emmerich, who reports excellent effects in diphtheria from injections of erysipelas antitoxin.

To judge from my experience, I think there is nothing which can equal the physiologic treatment in producing a powerful reaction which, by the way, is superior to the one caused by the antitoxin, inasmuch as no ill effects are produced, as is the case in the serum treatment.

The serum-therapy stands on the same footing as the drug treatment, being only a matter of belief, and as long as a physician believes in the latter, he can not be blamed for believing in the former. But those practitioners are to be blamed who in their enthusiasm go so far as to call other physicians criminal, because these do not follow their way of jumping at any new treatment which is presented. The day will come when this order of things will be reversed, and those using the serum treatment will be placed in the same light as those not using it to-day. And the adroitness with which those enthusiasts of to-day will extricate themselves from the affair will only be equalled by the facility with which they will take up the next fad that comes along. If there were a hundred diseases which could be treated on the principle of the serum-therapy, and in ninety-nine this treatment would prove to be a failure, there would yet be physicians who would try it in the hundredth, although their experience in the other ninety-nine diseases should have taught them that the system they followed was erroneous.

The serum-therapy will undoubtedly be the prevailing treatment in diphtheria for a long time, because it is used in an acute disease in which any treatment has a good chance, especially if it is much less harmful than the drug treatment. The serum treatments we have had and will have in chronic diseases, will only be of short duration. But also the antitoxin treatment of diphtheria will not last forever. Some severe epidemic may occur in which the diphtheria antitoxin, alone or in conjunction with the streptococcus antitoxin, will be

found wanting in spite of a timely employment. And then it will go the same way the other inoculations and vaccinations for syphilis, anthrax, cholera, hydrophobia and tuberculosis went. Yet I want to say that I am far from thinking that those industrious investigations which have been and are being made concerning the serum-therapy, are in vain. On the contrary, they will be of great benefit to mankind, for they will finally convince us that we can not rely upon the blood serum of a horse or any other animal, not even on that of another man, but only upon our own individual serum.

And they will teach us that only by a hygienic way of living can we immunize ourselves; that means, improve the physiologic functions of our body and the bactericide power of our blood. They will also teach us that in disease we can rely upon the same agents only, on which natural immunization is based and of which physiologic treatment consists.

643 W. 12th Street.

GENERAL SEPTIC PERITONITIS TREATED WITH SEPTICEMIC SERUM.

BY W. A. MACFARLANE, M.D.

CHICAGO.

Mrs. H., age 30; general health fairly good; eight years ago gave birth at the eighth month to a healthy child; it lived three days. She became pregnant in about one year and at end of third month miscarried. About five years ago was called to see her for the first time. On examination found os dilated to some extent, with double laceration of cervix; most extensive on left side. Found patient had had considerable hemorrhage. Decided to prevent miscarriage if possible, as they were anxious to have children. Succeeded in stopping the hemorrhage to some extent before leaving. Was called the next morning in great haste; found her considerably prostrated from loss of blood and flowing profusely. Decided at once to dilate and deliver, which was done as rapidly as possible, but not until she was very much prostrated, being obliged to use a number of hypodermic injections of digitalin, strychn. sulph., glonoin and brandy. Found great difficulty in removing all of the placenta as it was considerably adherent. Left her resting well and heart acting as well as could be expected. Called next morning and curetted, removing some small pieces of membrane, washed out uterus with sol. bichlorid, 1 to 2,000, and repeated several days, patient making fairly good recovery.

Treated her after for some time, getting her in general good health and advised her to submit to an operation for lacerated cervix, as I decided that would be the only hope of her ever going through to full term. Could not find any hereditary taint as far as could be ascertained, although could not get perfectly clear history, as she was very young when leaving Europe. She continued in very excellent health for over two years and became pregnant again, continuing so without any apparent danger until end of seventh month, when I was called suddenly and found her in true labor; delivered her of a large, healthy child, apparently perfect in every way. Used every means possible to save the child; died the fifth day. Patient made good recovery and became in good health again and continued so up to Jan. 3, 1896, being two years since last premature labor and enjoying as good health as could be desired, except occasional visits to my office

complaining of some slight stomach derangement. January 3, was called and on examination found os slightly dilated with considerable hemorrhage. Prescribed tinct. opii, gtt. x in water every three to four hours; visited her at 9 P.M., hemorrhage slight, resting quietly, without any pain. January 4, 10 A.M., patient stated to me that at 5 A.M. she had had profuse hemorrhage and strong pains from 5 to 6 and that everything had come away. On my making examination found that there were still some placental remains. Removed a large piece, all that I could find; concluded that I had removed all. January 5, 9 A.M., temperature 99.6, pulse 90, hemorrhage normal, patient stating that she was feeling well, taking considerable nourishment and had rested well during the night. Examined again for placental remains, found os still slightly open, but could not find any indication of remaining membrane. January 6, 9 A.M., temperature 100, pulse 96; patient had rested well during night, taking considerable nourishment, principally milk. Discharge normal. January 7, 10 A.M., found patient not so well; temperature 102, pulse 108. Gave her intra-uterine injection sol. bichlorid 1 to 2,000 and prescribed salophen and phenacetin $2\frac{1}{2}$ grs. each in one powder every three hours; tr. nuc. vom., 3 m.; digitalin, gr. 1-80; tr. capsica, 2 m.; quinia sulph., 2 gr. in syr., one teaspoonful every three hours; brandy every two hours. Called at 9 P.M., temperature 101.5, pulse 102, sweating freely. Was called at 2 A.M. by husband, stated over telephone that patient was in very severe pain and had chills and pains over lower portion of abdomen. Ordered druggist to put up morph. sulph. 1 gr., and divide into four powders, to be given every three or four hours in a little water. Flaxseed meal, stramonii fol. in hot poultice to be applied over pelvis. January 8 visited patient at 8 A.M., and found her suffering severe pains; temperature 105.4, pulse 132 and thready, and in profuse perspiration; features pinched and sallow and frightened expression of face, loss of all hope, marked tympanites over whole of abdomen, complaining of the pain being most severe and extending up sides of abdomen, vomiting continuously; had not been able to retain anything on stomach since 4 A.M., not even a teaspoonful of water; small pellets of ice being dissolved in mouth would cause severe retching. Decided to curette at once, which was done, assisted by Dr. P. T. Burns, getting considerable broken-down tissue, odor very great. Washed out uterus with as hot water as could be borne, mopping out uterus with pledgets of absorbent cotton and applying to inner surface of womb sol. equal parts carbolic acid and iodine and placing over external part absorbent cotton pad; applied poultices of flaxseed meal and stramonii fol., which relieved pain to some extent. Prescribed small doses of dilute phos. acid in a little water at frequent intervals, and bromo-caf. to allay irritation of stomach, ordering small doses of mag. calc. as soon as condition of stomach would permit. Did not attempt to give anything in way of medicine or nourishment for several hours and then began with small amounts of liq. peptonoids and champagne. In fact, she was not able to retain anything of any consequence on the stomach for the next twenty-four hours. I telephoned at once to Truax & Co. for septicemic serum, Dr. Burns agreeing with me that there was not the slightest hope for her unless there might be some benefit to be derived through the aid of septicemic treatment and we had at that time but little faith in it. I

secured the serum at 7 P.M. and gave her 20 c.c.; temperature still over 105, pulse 130, and sweating profusely; vomiting very severe; occasionally retaining a little champagne and water in teaspoonful doses. Symptoms but slightly, if any, improved from morning. Remained until 9 o'clock. At that time temperature 105.6, pulse about the same as at 7 P.M. January 9, 9 A.M., was very much surprised on examination to find such marked improvement: temperature slightly less than 102, pulse 112, stronger and quite full; pain very much lessened with less tympanites; had been able to retain medicines, stimulants and some considerable nourishment; had slept possibly two or three hours during the early morning, being disturbed, as she stated, by bad dreams; gave her the remaining 5 c.c. and procured another bottle 25 c.c., and gave another injection, 10 c.c., same evening. January 10, 9 A.M., patient much improved in every way: temperature 101.5, pulse slower, stronger and more compressible, perspiration free, pain slight, tympanites lessened; had not vomited for twenty-four hours, but had occasional slight nausea. Returned at 8:30 P.M. and gave 10 c.c., making 45 c.c. in all: temperature 101.5, pulse improving, patient hopeful, pinched expression of face and sallowness less marked; stomach could now retain all nourishments, oatmeal gruel, buttermilk, sweet milk, broths and beef peptonoids, etc. Pushed medicines that had been set aside since beginning of nausea, which was gradually diminished as she improved from day to day, until dose three times a day was given. January 11, 9 A.M., temperature 101, pulse 108, stronger and fuller, still sweating profusely, especially while sleeping; rests fairly well, but broken by dreams; stomach in good condition, taking large quantities of nourishment; does not suffer pain except occasionally; hot poultices still applied every three or four hours to the abdomen; and intra-uterine injections of hot water given every day (10 to 12 quarts); sol. of bichlorid 1 to 2,000 (2 quarts) given immediately after. January 12, 9 A.M., temperature 102, pulse more rapid; otherwise apparently doing as well as when I saw her the morning previous. January 13, temperature and pulse as on the 12th. January 14, temperature 100.5, pulse 104. Temperature after this date never rose above 101 at any one time, but usually remained between 99 and 100 for several days. heart apparently showing the effect of the sepsis longer. January 16, temperature 99; patient states that she feels well but very weak. Asks to be allowed to sit up; sweating lessening each day; has been given alcohol baths twice a day; still sweats considerable while sleeping; her rest is not now so much disturbed by dreams. Removed poultice and gave an alcohol bath. Two thicknesses of cotton wool placed over whole of abdomen and fastened by wide bandage, drawn tightly over lower portion. January 17, 10 A.M., she sat up about an hour; temperature about normal; complains of weakness, stimulants and tonics have been given freely, taking large quantities of milk and gruel, buttermilk principally, sufficient amount of mag. calc. to keep bowels active, has been given throughout the course of the disease. Kidneys have acted well since stomach being enabled to retain fluids. January 20 visited her for the last time: temperature normal, pulse 90; sitting up several times each day.

Summary.—This case undoubtedly demonstrates the efficacy of the serum in cases of septic peritonitis. Even after thorough curetting, swabbing with iodine

and carbolic acid and irrigating the uterine cavity the temperature did not vary one degree, but the first injection of serum brought all of the symptoms below the danger line in twelve hours and quieted the extreme irritation of the stomach, enabling it to retain medicines and nourishment, which we had not been able to do, in twenty-four hours from 4 A.M., January 9, to about the same hour January 10, twelve hours after injection of serum. It also produced continuous and profuse perspiration. This latter condition was without doubt instrumental in draining the system of vast quantities of sepsis and being now enabled to take in unlimited quantities of fluids; there was no special drain on the vitality of the patient. Thorough action of kidneys and bowels, no doubt, also assisted in the process of elimination.

Another great feature in this treatment is the surprisingly rapid convalescence of the patient. No sooner was the infection conquered when the patient appeared to be at death's door than within twenty-four hours the change was from a dying woman to one asking to sit up. Had her heart been in relation to her temperature I could have discharged her as cured three days earlier.

REPORT OF RESULTS AND RECOVERIES OBTAINED BY THE USE OF ANTI- TUBERCLE SERUM.

BY A. M. HAYDEN, M.D.

CHIEF SURGEON ST. MARY'S HOSPITAL
EVANSVILLE, IND.

The results I have obtained from the use of Paul Paquin's Antitubercle Serum are as follows:

Case 1.—My first case was one with large cavities in left lung, hepatization of the lower portion of right lung; had a great many hemorrhages, sputum contained large quantities of bacilli: weight 120 pounds. Treatment commenced May 10, 1895. In three months tubercle bacilli disappeared from sputum entirely, and it has remained free from them ever since. The cavities in left lung healed up, with great contraction of the chest on that side, three or four inches, which has remained so. The patient ceased to expectorate heavy sputa. Has had no hemorrhages since treatment began. He has weighed 140 pounds for the last six months: rides a bicycle, eats well and commences his duties as assessor to-morrow. After the first three months, I gave him from one to two ounces, only at intervals of one and two months. I am satisfied that he would have been dead long before this if he had not had the serum.

Case 2.—A young man 25 years old. Family history was that of tuberculosis. His sputum contained quantities of tubercular bacilli: weight 110 pounds: had been West without being benefited. He had night sweats, fever and all symptoms of the dread disease. I commenced his treatment Sept. 8, 1895. Gave him 56 daily injections of 35 ms. each. Tubercular bacilli disappeared from sputum and he gained ten pounds in weight. January 20 I commenced again and gave him 16 more injections, during which time he gained five pounds, which is more than he had ever weighed in his life. He is still in splendid health and says he is feeling better than he ever did. I advised him, to-day, to take another ounce of the serum, to guard against relapses.

Case 3.—A young man with long standing hip-joint disease. I gave him one ounce in January, 1896, during which time he gained sixteen pounds and improved greatly in general health. He then stopped for two weeks, during which time he ceased to gain in flesh. He again commenced taking the serum, taking one ounce more, and gained ten pounds. His health has been much improved since.

Case 4.—Patient was a man aged 40. Several brothers had died of tuberculosis. He was taken sick in November, 1895, with cough, night sweats and fever. His family physician treated him until January, 1896, when I was called. He was much emaciated, no appetite, had night sweats, fever, etc. While he coughed almost incessantly, he did not expectorate. I failed to find any lesion of lungs in physical examination.

His liver failed to act well (chalky evacuation, etc.). His family physician had treated him faithfully, without results, and was satisfied that the patient was suffering with tuberculosis of the liver and other glands. I advised the use of serum, stating to patient that if his trouble was tuberculous he would be benefited; if not, it would do him no good. He consented and we started on the treatment. The improvement commenced at once and in sixteen days he had gained sufficient to get up and walk a square to a grocery and get weighed, and found that he had reached 150 lbs., his usual weight. We then stopped the treatment for ten days, at which time the patient requested me to commence again, saying that his appetite was not so good and that he was having night sweats again. I ordered another ounce of the serum, but before commencing treatment I had him weighed and found that he still weighed but 150 lbs. After taking the sixteen days' treatment I found that he weighed 170 lbs., a gain of 20 lbs. He is now at work and says the serum saved his life. After I commenced the serum, I stopped all other medication.

I have a case of laryngeal tuberculosis that has just finished the second ounce—thirty-two days' treatment. She has gained in weight, is a better color, and Dr. Lehardy, a throat specialist, who has been examining her larynx, says the ulcers on vocal cords are improved.

I have one lady patient with acute tuberculosis of lungs, who has taken two ounces, thirty-two days' treatment. She gained during the first two weeks, since which time she has lost, and at present her condition is not any better than when I commenced her treatment. However, she has a mixed infection.

I am also treating another lady who has pulmonary tuberculosis. She has taken $1\frac{1}{2}$ ounces, twenty-four days' treatment, and is improving very rapidly. I am satisfied that she will recover.

All my cases have been diagnosed by the presence of tubercular bacilli in the sputum, as well as by physical examination, except the one with tuberculosis of the liver. Diagnosis in that case was based on family history and physical signs, together with the fact that he went from bad to worse in spite of the best medical treatment.

I will stick to the serum treatment, at least until something better is found. It has proved much better, in my hands, than any other therapeutic agent in tuberculosis.

A CASE OF ASTASIA-ABASIA.

Report read and patient presented before the Philadelphia Neurological Society, April, 27, 1896.

BY AUGUSTUS A. ESHNER, M.D.

PROFESSOR OF CLINICAL MEDICINE IN THE PHILADELPHIA POLYCLINIC;
PHYSICIAN TO THE PHILADELPHIA HOSPITAL.

Astasia-abasia may be accepted as a convenient designation for a clinical condition characterized by inability to stand or to walk, but not dependent upon actual paralysis. Blocq (*Revue générale de Clinique et de Thérapie*, 1889, No. 11, p. 165) proposed the explanation that patients thus affected had lost the memory of the specialized movements requisite for the performance of those acts. As a rule sensibility, muscular power and coördination are preserved, though the disorder may be associated with hysteria or organic disease of the spinal cord.

I wish to add a further case to the not very large number already contributed to the literature of the subject. The patient was a married woman, 46 years old, who was a housewife and whose husband was a cigar-maker. She was born in Philadelphia and her family history presented a number of interesting features. One of three of her sisters living was paralyzed for three years after taking a sea-bath and was cured by the "laying on of hands." She married four years later and never had any return of the motor

disturbance. A second sister was described as "extremely nervous." Another sister was dead in consequence of "dropsy of the brain," it was supposed. The patient had had measles, whooping-cough, chickenpox and intermittent fever in childhood and articular rheumatism at the age of 18 years. Menstruation appeared at 15 and ceased at 42, and was unattended with difficulty. The woman had borne an illegitimate child, which died at the age of 21 months of marasmus. For four months afterward she suffered from pains resembling labor pains. She admitted having lived the life of a prostitute between the years 1870 and 1872, though she was not aware that she had ever been infected with venereal disease. It was during the period named that she married. In 1871 upon the suggestion of her husband she smoked a cigar in the hope of relieving toothache. She found that she liked the sensation and she continued to smoke cigars or a pipe until 1892, when, as she reminded me, I first saw her at the Jefferson Medical College Hospital. I fail to recall the details of her condition at that time, but I believe a diagnosis of nicotineism was made.

In 1878 "speech was partially paralyzed," the disturbance having set in abruptly and being unattended with any concomitant disease. For ten minutes the woman was totally unable to speak and only with difficulty for two or three hours more. At the time of certain shocks later to be referred and under other conditions not readily defined, such as bad weather and when the patient speaks rapidly, speech becomes somewhat thick.

In 1887 the patient fell upon the ice, striking the sacral region. Improvement followed local applications. Later she fell again, striking the same place. Some of her present symptoms followed an attack of influenza in 1890.

In 1892 the patient lived in a damp, moldy house for three weeks, and suffered from cough, together with numbness of the feet, which gradually extended upward to the level of the stomach. Upon change of residence the sensation descended and finally disappeared. Later, however, there were present for a time girdle-sense and numbness of the toes. The woman then passed through a period of nine months quite free from all symptoms.

In 1893 the patient observed that contact of the hands with cold water and exposure to drafts of air would cause her to fall. Already in 1892 with the numbness in the toes there had been difficulty in walking, which has grown progressively worse, so that in the past two years the patient has been unable to walk alone and without support. She has also at times a peculiar sensation, compared to pinching, referred to the umbilical region and which both she and her husband were fearful was due to the presence in the stomach of some animal swallowed with drink. A similar sensation is referred to the nape of the neck when the hands are put in cold water or the patient is exposed to a draft of air. The patient complains irregularly of icy coldness of the feet, extending half way up the legs, and at times of a sense of burning in the same parts. She is as a rule obstinately constipated and has noticed a new symptom this year: She can not distinguish between the desire to defecate and that to urinate, that is, she may feel a desire to evacuate the bowels and may only pass water, and vice versa. She thinks the rectal and vesical sphincters weak. Digestion is poor. In the last year sneezing

induces a sense of chilliness. The appetite is fairly good. The tongue was slightly coated and dry. The teeth are stained black. Sleep is good and refreshing. Rarely there is headache, which when present is supra-orbital and vertical. Occasionally there is vertigo. On inclining the body forward and flexing the trunk after meals vomiting results. Sometimes, it was reported, food returns without entering the stomach. The patient is annoyed by a sense of the presence of hair in the throat. She has never had a convulsion or lost consciousness. She suffers a good deal from flatulence, which sometimes precedes a diarrheal discharge.

The patient appears quite unable to walk unsupported. When asked to make the attempt she throws her arms about herself rather incoördinately and sways upon her feet. She is unable to stand at all with her feet together. She maintains that the right leg feels heavy. She can walk up and down stairs with the aid of the banister. She volunteers the information that she does not fall when her feet are warm, and that she does not topple over in her own room. The knee-jerks are greatly exaggerated and ankle clonus is represented by a few contractions of the foot upon flexion. So far as can be determined there is no other derangement of motility and the muscles used in walking and standing possess the power of performing other acts. Sensibility appears generally preserved. The right pupil is a little smaller than the left; both are regular and react to light. The patient is rather pallid and of poor nutrition.

With great preciseness the patient related, as she did all the details of her case, that she had suffered from three shocks, one on Jan. 30, 1894, in which she lay helpless, though conscious, for half an hour; a second on Jan. 1, 1895, in which the same condition persisted for an hour and a half; and a third on Feb. 10, 1896, lasting for ten hours. She subsequently recalled that she had a fourth attack on Feb. 15, 1896, lasting for twenty hours. The patient has also at different times passed unusual substances from the bowels; on one occasion what she describes as a kind of tube; on others small white bodies looking like eggs, also hairs; again something resembling a small animal supplied with many feet; on still another occasion something having a white head and black eye. Two specimens of such substances submitted to me as having been passed, respectively, Nov. 20, 1894, and March 29, 1896, presented gross and microscopic appearances of vegetable fiber.

After taking a pill of aloes and asafetida for several days the patient found that she always fell backward whenever she approached a receptacle containing water. She pointed out a small spot as large as a pin-head upon the left ear which for two or three months has from time to time been the seat of intense burning. She stated further that a sister with whom she slept for a time had suffered from cold feet and she wondered if she might not have derived the coldness of her own feet from that circumstance.

The patient is extremely detailed in her account of herself, and in this she is ably supported by her husband, who supplements by suggestion or otherwise such facts as the patient herself may have failed to mention. At times they may differ in their respective versions, but altogether they are quite in accord.

The case impresses itself upon me as clearly an hysterical one, all of the symptoms and attendant cir-

cumstances, including the family history, supporting such an opinion. It must none the less be viewed with a good deal of seriousness and the prognosis must be guarded. If the patient could be removed from her present surroundings, if the current of her life could be entirely changed, the prospect might be more hopeful. This case and allied ones can not be viewed as a manifestation of merely functional disturbance. It is far more probable that there have taken place nutritional changes, which become more and more pronounced with the progress of the case, and which in time may lead to structural alterations. When only the nutrition of the nervous system suffers the prognosis is good under favorable conditions, but when changes in structure have resulted permanent and perfect cure is beyond the range of hope.

REPORT OF THREE CASES OF POLYMYOSITIS ACUTA: WITH REPORT OF POST-MORTEM ON ONE CASE.

BY J. BAILLIE KELL, A.M., M.D.

LATE CHIEF SURGEON ESPAGNOL AMERICAN STEAMSHIP COMPANY.
BARNHILL, OHIO.

The report of a case of polymyositis acuta, by Dr. J. B. Herrick, in the *American Journal of the Medical Sciences* for April 1896, and his reference therein to the literature of the subject especially as to its bearings upon its etiology and the evident interest taken by the profession, relative to this feature of these cases, leads me to make the following brief report, which I take in the form of an abstract from my individual case report book, of the history of three cases, occurring simultaneously in the same locality, of what I at the time considered typical cases of polymyositis acuta. Subsequent study and observation of this class of cases have only tended to confirm the diagnosis made at the time. One of these cases terminated fatally within seven days after my attention was first drawn to the patient's condition; the remaining two terminated in a rapid convalescence and uninterrupted recovery. Most observers of this morbid condition have held it to be of an infectious origin, the case reported by Senator,¹ being of especial interest, where the patient was affected following the ingestion of stale crabs. Hitherto all efforts at isolating any specific organism or germ to account for the manifestation of this disease have proven futile; but the history of the cases I am about to relate makes it appear, that it is certainly due rather to a certain infective specific entity, in all probability belonging either to the class of toxin or to the gregarina. If there be anything of a contagious nature about these cases, then surely the conditions under which my cases developed, and ran their course, would certainly have had a tendency to produce the same disease in other members of the same group of men numbering forty-four who occupied the same sleeping quarters with these men all through the duration of their illness.

The histories of these cases are briefly as follows: In the month of July, 1893, the writer, while in the employ of a steamship company engaged in the New York, Cuban and Mexican trade, in the capacity of surgeon of a large 8,000 ton steel steamer, with one hundred and seventy-five firemen, coal-passers and

¹ Senator: Ueber acute und subacute multiple neuritis und myositis. Zeit. für Klin. Med., 1888, XV; and Ueber acute polymyositis und neuromyositis. Deut. Med. Woch., 1893.

water-carriers, exclusive of non-commissioned and commissioned officers on board, was lying in the closely land-locked harbor of Havana, Cuba. Two or three days after we had come to anchor, the first officer of the vessel, notified me, that one of his men was ill, and asked me to go to the fore-castle and examine him. I did so. On reaching that part of the ship I found two men, instead of one ill, of which the following are the brief histories:

Case 1. A. M., aged 23 years, a native of Savoy, France, states that last night on retiring to his bunk, and just as he was in the act of stretching out his limbs after reaching the recumbent posture, he felt a sharp, sudden stinging pain in the calf of his right leg as though he had been bitten by a spider. As we had been engaged during the day in loading the vessel's hold with bananas in the bunch, visions of huge centipedes came before him, and he very hurriedly kicked off his blanket and got out of the bunk to look for the insect, but failed to find any evidence of its presence, and a close inspection of the limb in the region of the pain, failed to disclose any wound, such as would be made by the bite of a centipede or any one of the several large and poisonous insects that live in this semi-torrid region. Feeling considerably relieved, he returned to his bunk and went to sleep, awaking about mid-night suffering with considerable dyspnea and pain in the left pectoral and cardiac area, the pain darting in short sudden stabs from the apex region around the chest to a point below the inferior angle of the left scapula. No disturbance of the stomach or bowels was present, while the kidneys acted normally throughout the illness. Upon examination the following day at 9 A.M. I found the right leg markedly swollen in the region just inferior to the popliteal space, the skin giving an edematous, harsh, branny sensation to touch, while upon the cutaneous surface was an eruption having features of both measles and an urticaria. This eruption was found on both extremities but only upon the flexor surface. A careful examination of the chest revealed some moist bronchial râles, the remnant of an old bronchitis; but otherwise the respiratory murmur was normal. Great interest was attached to the heart: percussion revealed the fact that the apex beat was removed at least an inch and a half farther to the left than was normal, while auscultation showed that the heart muscle was undoubtedly involved in some morbid process. The first and second sounds of the heart were strangely blended, instead of either being at all distinct, they gave forth a combined booming sound and reminded me more strongly than any other sound I had ever heard of a vessel upon the high sea, firing a salute with her big guns at a distance of from six to eight miles. The individual sounds were very indistinct and yet the combined murmur was at least three times as voluminous as it should have been. This sound was transmitted a great distance up the arterial system: I could distinguish it plainly in the carotid vessels and also in the subclavian, and here the sound had precisely the same characters as when heard in the cardiac area as though the sound was transmitted through a non-conductor of sound. The heart's pulsations in the erect posture was 120, in the recumbent 100 per minute. No apparent irregularity was noticeable. The pupils reacted to light normally, while the tendon reflex was slightly exaggerated. Ankle clonus was present also to a certain extent. None of the lymph glands were enlarged, and the patient denying any specific history, a thorough search failed to reveal any evidence of an old sore. Abdominal examination revealed a slightly enlarged spleen and liver, the latter though to a very small extent. Examination of bladder, rectum and prostate revealed them in a normal condition. Six hours later I saw the patient again, his left forearm was now involved, and if anything far more painful than the affected leg. Here especially the supinator longus and pronator radii teres were affected, the bellies of these muscles were badly swollen, while the skin covering them had the same edematous, hard, branny feeling to the sense of touch, as that on the leg. As the supinator approached its tendinous insertion, it was seen to be swollen to at least three times its normal volume, and so exceedingly painful was pressure of any kind on the affected leg, chest and arm, that the patient even dispensed with a blanket for covering his person, he stating that its weight produced pain. At this time I excised a small portion of the supinator longus for microscopic examination, which under the lens presented the usual evidences of acute muscular inflammatory action. Muscle striation had almost and in some places completely disappeared, while the individual muscle fiber were many of them greatly swollen, and presented, some a granular condition, others a hyaline degeneration. Between the muscle fibers could be seen

many large cells with large nuclei, believed to be proliferation cells: the blood vessels of the part seemed to be greatly enlarged, in some localities presenting evidences of a developing periarteritis. In one place could be seen a white blood corpuscle engaged in the emigratory act, passing through the vessel wall, into the surrounding inter-fibrillary spaces. All efforts along the line of forming cultures from the fluid exuded by pressure from the muscle sections were absolutely futile, resulting in each instance negatively.

As it is a notorious fact, that sailors and others leading a seafaring life, live almost exclusively upon pickled and salted pork, hence a very careful search was made for trichinae, but resulted negatively. This man continued to grow worse, until owing to pressure paralysis of the palato-pharyngeal muscles, he was unable to swallow, even liquids returning through his nose on attempting deglutition. His temperature remained throughout his illness, which was of six days duration, at about 100 degrees F., except just previous to his death, when it rose instantly to 106 degrees. The patient gradually progressed from bad to worse, until death came to his relief, apparently due to paralysis of the respiratory muscles.

Post-mortem, ten hours after death: Body well developed and nourished; considerable hypostatic congestion. Eruption on skin has totally disappeared; abdominal adipose abundant. Brain is in a normal condition; venous sinuses full of blood; lungs nil. Heart muscle found to be greatly swollen, the thickness of its muscle being greatly increased. Microscopic sections of cardiac muscle, intercostals, supinator longus, pronator and gastrocnemius, revealed simply the same pathologic conditions as were found in the examinations of the muscle section removed from the supinator previous to death. The stomach, liver and bowels were normal in appearance; the spleen was markedly enlarged and considerably softened. Sections of it placed under the lens, revealed a vast number of leucocytes far beyond the number usually found in the spleen in health; the parenchyma of the spleen also presented a granular and in some locations, a hyaline degeneration. Periarteritis was also a prominent feature of the pathology of the spleen. The bladder, rectum, prostate gland and associated glands presented no deviations from the usual normal condition. Death in this case was undoubtedly caused by paralysis of the respiratory muscles, caused by an enlargement in their bulk, to the degree that the ensuing pressure caused a paralysis. I have stated that all efforts in the direction of isolating a germ or special forms of bacteria to account for the disease by cultures or gelatin or agar, resulted in a failure, so after death was it likewise in several separate experiments made with the tissues and the juices expressed from the cut sections from six different locations. While it is doubtless due to the presence in the blood of either a toxin or one of the different forms of gregarina, the various methods of precision which science has placed in our hands to date, are not sufficiently efficient to demonstrate their presence in the tissues or the blood.

Case 2. At the same time that I was called to see A. M. I found B. F., aged 26 years, an American by birth, lying in his bunk, groaning considerably from pain in the region of the hip. Upon examination I found the right gluteal region greatly increased in size; the cutaneous surface had the same tense, hard edematous feeling that was found in A.M.'s case. A markedly papular eruption soon developed upon the right buttock; this swelling and eruption gradually extended to the extent of three inches below the major trochanter. Five hours after first seeing this patient I cocaineized a small area in the affected region, and removed a small piece of the gluteus maximus muscle. Upon making the incision into the muscle a quantity of sanguinous fluid, approaching two drams in amount, poured forth from the cut section. This I managed to collect in a small porcelain spoon, previously rendered aseptic. The muscle was deeply injected and well vascularized. Under the microscope this section of muscle

presented the same features as the section taken from A. M.'s case, only that the number of polynuclear cells was much larger, while the individual muscle fiber was far more granular in appearance, and in several localities the part presented simply the detritus of a previously preëxisting muscle fiber. Efforts at isolating germ life or bacteria upon either gelatin or agar resulted fruitlessly as they did in the previous case. Under the application of an active embrocation and iodid of potassium internally, the disease gradually disappeared, and in a few days the patient was as well as usual. I will add that this patient utterly denied all history of syphilis, and as he presented no signs of adenopathy his statement must be accepted.

Case 3.—S. S., aged 27 years, an Englishman by nativity; was almost precisely similar to Case 2, except in so far that the location of the inflamed muscle is decidedly different. This case did not develop until after twenty-four hours had passed after the previous cases were brought to my notice. The next afternoon following the day on which I saw the first two cases, the second officer called my attention to this man, saying his feet were swollen so badly he was unable to get his shoes on. I immediately went to see him and found his right foot badly swollen, especially just anterior to the tarsal arch. Here the tendons which can usually be so easily distinguished in this portion of the human anatomy, were swollen to the size of whip-cords, each tendon being at least one-third of an inch in diameter beyond its normal size. The movements of extension and flexion of the toes were greatly circumscribed and decidedly diminished, and any movement along this line gave rise to great pain, the patient crying out and resisting actively when I volunteered an effort at flexion and extension myself. The eruption was exceedingly characteristic in this patient. In some places could be seen the papulous eruption of a bluish coloration, such as is often seen in measles, while in other places would be found the large semi-circular, crescentic wheals so often found in urticaria. In two places only did I succeed in finding any of the eruptions which had progressed to the vesicular stage, and I was very careful to withdraw their contents, with a hypodermic syringe, previously rendered perfectly aseptic, for the purpose of ascertaining whether they contained any germ life. All work along this line resulted as all previous efforts in this direction had done, the fluid proving to be perfectly sterile without any evidence of germ life whatever.

What I have observed in these three cases, but other witnesses are silent on, so far as I can ascertain, is as to the site of the eruption. Invariably in these three cases the eruption was found upon the flexor surfaces of the limbs, and even when the pain would extend to the extensor surfaces and muscles, the eruption did not present itself in these situations. Whether this is because of the well-known anatomic fact that the cutaneous structure is much more delicate and thinner on the flexor than the extensor surface, I can not venture to assert. That it is true, is attested by the histories herewith given of the three cases.

Causation: The causation of these three cases has always been held to be very obscure. Senator,¹ quoting Herrick,² says: "Three hypotheses can be advanced as to its cause: 1, that it is due to a specific microorganism (vegetable parasite); 2, that it is due to a chemie poison (toxin); 3, that it is due to an animal parasite (gregarina)." In investigating the causes of the three cases presented above, the sanitary conditions of the city of Havana, and its closely land-locked harbor must be considered. Here is a city of 350,000 inhabitants, the poorer class of which are extraordinarily filthy in their habits and manner of living, with yellow fever an epidemic at the time referred to within the confines of the city, the registrar of vital statistics reporting a daily mortality of from fifteen to twenty deaths; while in addition to these there could be added thereto dozens of deaths occurring each week from the pernicious forms of malarial fevers. Typhoid fever was at this time especially

fatal throughout the entire island, following the encampments especially of the newly arrived Spanish soldiers. As is well known, all of the large sewers which carry off the excrementitious discharges from this populous city discharge their contents directly into the waters of the harbor, and the latter being virtually land-locked, having but one mode of ingress and egress, viz., a small channel not many yards in width between Moro Castle and the Fortress of Cabaniss. The amount of current which flows in and out with the flow and ebb of the tide is very small indeed. While there is some removal of the immense amount of excreta that is cast into the harbor each twenty-four hours, nevertheless a sufficient amount remains to be decidedly instrumental in developing yellow fever and other forms of malignant fever, as the history of the fever-ridden city of Havana ever since the year 1600 fully attests. Hence if this infected water will so affect the inhabitants who live on the shore close to its confines, what of the finny inhabitants who have their homes in the coral caverns in the deep bottom of this bay? On several occasions when our steamer had been anchored in toward shore, in close proximity to the mouth of one of the large sewers, I have observed different shoals of fish swimming along lazily close to the surface of the water, being apparently narcotized by some poisonous element in the water, as on casting an object toward them which ordinarily would cause them to instantly disappear, they would pay no attention to it whatever. It has been a habit with mariners and sailors while in this and various Mexican ports to catch fish, and by thus giving them a change of diet, the catch would form a very welcome addition to their mess. Upon the day previous to my being called to see the first of these three cases, A. M. succeeded in killing a large, twelve-pound red snapper that was floating in an apparently aimless manner close to the port opening. After stunning the fish with a blow he had no difficulty in hooking it with a pole-hook and drawing it aboard. Securing his prize, he cleaned it carefully and invited the other two individuals who were affected to assist him in disposing of the catch. That this fish was undoubtedly ill when struck and killed, anyone at all conversant or familiar with the habits of that denizen of the deep water known as the red snapper, will fully realize. As a rule, this fish rarely if ever approaches nearer the surface than six or eight feet, even though food in the form of bread and meat be thrown to them from the ship's deck. They will seldom dash to the surface and grab the morsel as will the more bold and fearless sea bass but will rather wait until the natural weight of the food causes it to descend to their level. It is so well known among sailors that the red snapper is a difficult fish to take that when a man is successful in catching one he is usually envied by his comrades. What was the physical condition of this fish? This is a question which in the absence of all parts of the piscine body, which had we preserved but a small portion, a microscopic section, several cultivations might have revealed some pathologic condition with special features, resulting in the isolation of a specific bacteria or some new form of germ life previously undescribed and unobserved, and would thus have provided us with a rational explanation of the morbid condition found in these men. The fish was probably narcotized by the ingestion of some of the poisons thrown out with the sewer discharges, whether this special poison

² Herrick, Dr. J. B.: Polymyositis Acuta, *American Jour. Med. Sciences*, April, 1893, p. 414.

belonged to the class of toxins or to that of the *gargarina*, it is certainly difficult to say. That it is true that the morbid condition found in these three cases was due to the ingestion of particles of this fish is evident from the fact that no more nor no less than the number which ate of the fish were affected, while forty-four other men all subjected to the very same conditions of daily life as those affected and occupying the same compartment with them as sleeping quarters, remained during the entire voyage utterly free from any contagion or infection.

ABDOMINAL HYSTERECTOMY FOR FIBROIDS OF THE UTERUS.

BY FRANKLIN H. MARTIN, M.D.

PROFESSOR OF GYNECOLOGY POST-GRADUATE MEDICAL SCHOOL, SURGEON TO WOMAN'S HOSPITAL, CHICAGO.

HISTORY.

Dr. Gilman Kimball of Lowell, Mass., was the first to deliberately plan and execute an abdominal hysterectomy for fibroids of the uterus. The operation was performed in August, 1853. On June 25 of that year, Dr. Walter Burnham of the same city removed a portion of the uterus for this disease. Ten years later, December 19, 1863, Koeberle did his first hysterectomy for fibroids, with external fixation of the stump of the uterus. He employed a metallic ligature with a special device for tightening it. Péan soon followed Koeberle and supplementing the latter's work by the free employment of force-pressure, and by publishing a systematic technique, which included the employment of steel pedicle pins over the metallic ligature for maintaining the pedicle extra-abdominally; his name became inseparably associated with hysterectomy by the extra-peritoneal method. Dr. M. M. Latta, Goshen, Ind., completed abdominal hysterectomy by tying the broad ligaments in sections down to vagina July 6, 1876. The elastic ligature for temporary ligation was first employed by Kleeberg, of Odessa, July, 8, 1878. In August, 1878, Martin recommended the provisional elastic ligature. Hegar about the same time recommended the elastic ligature for permanent intra-abdominal ligation of the pedicle.

In the evolution of abdominal hysterectomy many methods have been adopted and at different times each have had their advocates. The yearning for perfection has made confusion, owing to great efforts in many directions. In the early history of the operation the best results came with the extra-peritoneal method of treating the stump. This continued until the last few years when, with improved technique, greater experience, and to avoid unpleasant sequela the pendulum is irresistibly swinging toward the intra-abdominal pedicle. The history carries us through the following methods: 1, extra-peritoneal or Péan's; 2, intra-peritoneal or Schroeder's; 3, complete hysterectomy or Eastman's; 4, vaginal fixation or Byford's; 5, ligation of arteries outside of uterine tissue with intra-peritoneal stump or Stimpson-Baer method.

1. *Extra-peritoneal Method.*—The extra-peritoneal method as originally carried out by Péan, consisted in clamping the neck of the tumor with a wire clamp or *serre-nœud* including the broad ligaments with the appendages, preventing slipping of the constrictors with pedicle pins, excising of the tumor, fixation of the pedicle in the lower angle of the abdominal wound, and closure of the abdominal wound closely down to the stump. Joseph Price of this country

has improved this method until it is well-nigh perfect. His success with it has been phenomenal.

Hegar and Kallenbach modified it by carefully securing the pedicle after Schroeder's method and uniting it in the abdominal incision extra-peritoneally but beneath the closed incision.

Kelly and independently Van de Walker modified it by making temporary fixation, like Péan, until liability to hemorrhage had ceased, when the wire was removed and the pedicle allowed to contract into abdominal incision.

2. *Intra-peritoneal Method.*—This, as practiced by Schroeder, consisted primarily in constricting the pedicle with the Kleeberg rubber band, removing the tumor, paring down the stump, taking from its center a wedge-shaped piece of the bulky tissue, cauterizing the canal, closing the stump by strongly sewing together the edges of the wedge-shaped incision and finally sewing over all the peritoneal edges. The stitching of the stump was intended to be secure enough so that all subsequent oozing was made impossible after the final removal of the rubber ligature. The pedicle was then dropped, as is the pedicle after ordinary ovariectomy, and the abdomen closed.

This method was modified by Olshausen, Charles T. Parkes, Zweifel, Hofmeier and others.

(a) Olshausen modified by securing the pedicle with a rubber ligature, and sinking the whole by sewing over it the peritoneum.

(b) Charles T. Parkes modified it by ligating firmly with strong silk and cauterizing the tissues of the pedicle to firm bone-like condition with the actual cautery over a temporary clamp.

(c) Zweifel tied the pedicle firmly with a strong multiple ligature of silk, securing it in this manner in several parts.

(d) Marey of Boston, 1881, secured an intra-abdominal stump by sewing from the outer edge of one broad ligament to the other with thirteen cobbler's stitches; including in the process ovarian arteries, broad ligaments, uterine arteries and the stump of the uterus formed by the cervix uteri.

(e) Hofmeier carefully ligated the pedicle in its circumference without closing the cervical canal, and closed its abdominal end by covering with peritoneum. Drainage could take place into the vagina through the patulous canal.

(f) Goffe and Albert independently employed treatment similar to Hofmeier's, with the addition of applying a capillary drain through the open cervix into the vagina.

3. Complete Removal, Eastman's methods.

(a) In 1888 Dr. Mary A. D. Jones removed the entire uterus, including the cervix, by employing long hemostatic forceps for the lower portion of the broad ligament, and severing the cervix from the vagina.

(b) Joseph Eastman's method, 1889: The broad ligaments are tied off, including the appendages, the vagina opened posteriorly by elevating it by means of a special staff constructed for the purpose, which is held by an assistant, the vaginal edges are ligated with long ligatures which afterward serve to invert the edges into the vagina, and the cervix and stump progressively cut away. The peritoneum is sewed over the inverted vaginal edges, the abdominal wound is closed, and the vagina packed with gauze. The mass of the tumor, if cumbersome, may be cut away, previous to opening the vagina, by putting on a temporary rubber ligature.

(c) Eastman in 1884 enucleated the stump without first tying the uterine arteries by peeling the pedicle portion of the uterus with a serrated gouge, keeping inside of the uterine arteries in their course up the side of the uterus.

4. *Vaginal Fixation, Byford's Method.*—The broad ligaments are tied with silk and severed. The cervix is secured with provisional rubber ligature, the tumor cut away, the pedicle firmly tied with multiple silk ligatures, left long, the stump trimmed and closed with long silk ligatures, an opening made into the vagina in front of the cervix, the ligatures securing the pedicle carried through it by traction on them, the stump inverted into the vagina, the peritoneum over the inverted cervix closed by stitching the bladder peritoneum to that covering the pedicle, closure of the abdominal wound, and finally placing a special hemostatic clamp on the inverted pedicle in the vagina.

Meinert, independently of Byford, suggested pulling the pedicle into the vagina through Douglas's cul-de-sac, but is not known to have accomplished it.

Polk, of New York, has removed the entire cervix, stitching the vaginal stump to the abdominal wall.

Thus briefly do we get an outline history of the development of the technique of this important operation. From the beginning the struggle was in the direction of accomplishing complete hemostasis of the pedicle without the necessity of invariably fixing it in the abdominal wall. It was soon demonstrated that no pedicle comprised of cervical or uterine tissue could be made bloodless by any amount of ligating with non-elastic ligatures which could not from time to time be tightened as the tissues shrunk. Hence with silk, steel or clamp hemostasis it was necessary to fix the pedicle externally in order that they might be tightened in case of necessity. Elastic ligatures, while they accomplished perfect hemostasis, experience soon demonstrated were not safe ligatures to bury, because they frequently gave rise to suppuration when the strangulated pedicle was dropped. At last it seemed inevitable that external fixation of the pedicle was to be the only safe method of accomplishing abdominal hysterectomy. The displacement of the tissues necessary for abdominal fixation and its distressing sequelæ—bladder pressure, painful cicatrix, dragging pain, herniæ, depressed cicatrix, etc., made surgeons slow to accept that means as final, while at the same time there seemed no other alternative. The vaginal fixation of Byford's which came in late in the race, solved many of the difficulties, and if something better had not speedily followed, it would have become the ideal method of pedicle fixation. But when the struggle was at its height the whole problem was suddenly solved by the application of a simple little principle described by Stimson in 1889 and practiced by others and redescribed and emphasized by Baer, of Philadelphia, in 1892. The principle consists in obtaining hemostasis of the uterine stump by ligating its blood supply outside of the uterine tissue before it reaches its substance; or, in other words, by ligating the uterine arteries at either side of the cervix. Eastman had practically accomplished the same thing in his old operation of complete removal of the uterus the same year Stimson announced it, but none of us recognized the principle involved, nor did he announce with sufficient emphasis why he succeeded. So Stimson and Baer get the credit of promulgating and establishing a great but simple principle, and the

uterus is removed every day now, partially or wholly, and the pedicle dropped with perfect impunity.

5. *Ligation of Arteries at Side of the Uterine Tissue with Intra-abdominal Stump; Stimson-Baer Method.*—This method is accomplished by ligating the ovarian arteries with or without the broad ligament, severing the broad ligaments after placing hemostatic clamps on the uterine side down to the uterine arteries, ligation of the uterine arteries, severing the uterus at the cervix, cauterizing the cervical canal, trimming the cervix, closing the stump with catgut or silk, burying the pedicle with peritoneum, closing the broad ligaments with a running stitch of catgut, and closing the abdominal wall.

Senn modifies this operation by stripping the tumor of its peritoneum in front and behind for three inches, severing the tumor at its bottom so as to leave the peritoneum like a cuff and then fixing this cuff open to the lower angle of the abdominal wall, draining it with iodoform gauze until all danger of hemorrhage has ceased, when the gauze is removed and the cuff closed by closing the abdominal wound by tying sutures inserted at the time of the operation. Stimson-Baer principle when thoroughly carried out makes Professor Senn's precautions superfluous.

INDICATIONS FOR ABDOMINAL HYSTERECTOMY FOR UTERINE FIBROIDS.

Successful abdominal hysterectomy is the only absolutely sure cure for large fibroids of the uterus. Ergot, electricity, ligation of the blood supply will cure a certain percentage, but hysterectomy removes at once every vestige of the tumor and with it the uterus on which it propagates.

The operation of abdominal hysterectomy, in its present condition of perfection, in the hands of experienced operators should be the operation of selection in all fibroids which can not be removed by vaginal hysterectomy when the patient is in a physical condition which will not jeopardize her immediate recovery from the operation.

Multiple intramural fibroids of every kind which are producing distressing symptoms should be submitted to hysterectomy because there is no absolute cure for them by any other means.

Subperitoneal fibroids when from multiple developments can only be removed by abdominal hysterectomy; no other treatment will reach them.

Interstitial fibroids of large size, of hemorrhagic nature, if the patients are in a fair physical condition, should always be treated by abdominal hysterectomy.

Cystic fibroids can only be cured by hysterectomy. Any form of treatment less radical only aggravates these cases.

Suppurating fibroids imperatively demand hysterectomy.

Fibroids complicated with pelvic suppurations, pyosalpinx, suppurating ovaries or appendicitis, should be removed at the same time that the pelvis is cleaned out.

Large fibroids complicated with pregnancy where there is the slightest doubt of a successful normal ending of the condition of pregnancy, demand abdominal hysterectomy.

ABDOMINAL HYSTERECTOMY—TECHNIQUE.

Uncomplicated Case.—The writer adopts the Stimson-Baer operation for uncomplicated hysterectomies for any cause. The abdomen is opened with a liberal incision which will allow of easy delivery of the

tumor. The lower end of the incision is carried well down to within an inch of the symphysis pubis. If the bladder is unusually high the incision at the lower end need not include the peritoneum. The tumor should next be delivered by lifting it out with the hand or a strong pair of vulsellum forceps fixed in the fundus of the uterus or top of the tumor. It is very necessary that the tumor be delivered at this point in order to continue the work of removal intelligently. As soon as the tumor is outside of the abdomen the general peritoneal cavity should be shut off with liberal packs of dry sterilized gauze. If the intestines are inclined to protrude the abdominal incision may be closed above the pelvis with a temporary silk suture. The broad ligaments are next clamped with a strong pair of long jawed hemostatic forceps far enough away from the uterus so that another forceps of the same character may be placed between it and the uterus, and low enough to include all the upper portion of the broad ligament with the ovarian arteries. The broad ligaments on either side are next severed between the forceps to the lower limit of their bite. This frees the uterus well down to the cervix and the region of the uterine arteries.

FIGURE 1.

The peritoneum on the anterior surface of the uterus is severed at the utero-vesical fold transversely, the ends of the incision ending at the two provisional forceps placed on the uterine end of the severed broad ligament. The cervix is then stripped of its peritoneum anteriorly, care being exercised to separate the bladder from it, thoroughly. After the uterus is well denuded of its peritoneum below the point marked off by the knife, and the bladder is well separated a gauze sponge of small size may be placed temporarily on the denuded surface. It is well at this point, too, to peel off a small flap of peritoneum from the posterior surface of the lower portion of the body and cervix, beginning an inch above the point at which the stump will be made, and denuding to a point just below it. The uterus is now drawn well to one side, retractors placed on the opposite side and the uterine artery is secured by placing around it a strong silk or antiseptic catgut ligature. The artery is securely tied and the ligature left long. A pair of artery forceps is placed on the tissue secured by the ligature between it and the cervix, and the tissue severed between the forceps and the uterus. The opposite side is treated in the same manner. The uterus is now removed by severing it at its neck. The inci-

sion is begun about an inch above the vaginal attachment anteriorly and posteriorly and carried toward the uterine canal in such a way as to leave the uterine stump, a hollow wedge with the apex at the cervical canal, and the sides of the wedge the anterior and posterior surfaces of the stump, which when approximated, form flaps which completely shut off the cervical canal and the cavity of the pedicle from the abdominal cavity. The uterus can be severed from the cervix best with a knife. As soon as the flaps are begun posteriorly and anteriorly the stump should be steadied and controlled by securing these flaps in strong lock forceps. (Fig. 1.) As the uterus is severed great care should be exerted not to infect the abdominal cavity with any septic matter which may be in the uterine canal, and the cervical canal must be immediately cauterized or otherwise rendered sterile.

The stump is now closed by uniting the two flaps with inversion sutures of antiseptic catgut. The simplest and most satisfactory method of suturing for this purpose in my opinion is the one employed by Prof. A.

FIGURE 2.

Method of suturing the pedicle in hysterectomy: a, pedicle unclosed; b, pedicle and method of introducing inversion stitch; c, the completed pedicle.

H. Ferguson, Fig. 2. The stitch is an interrupted one as shown in the drawing, and completely closes the flaps without penetrating their cut surfaces. Prof. Ferguson uses the stitch in bowel surgery to take the place of the Lembert suture. When the pedicle is closed it is dropped.

At this point the upper portion of the broad ligament upon which the provisional hemostatic forceps were placed must be cared for. It contains the ovarian artery as it passes along the broad ligament parallel to the infundibulo-pelvic ligament which should be securely tied. Next if the pedicle of the broad ligament is long enough so that it can be easily included in the ligature left long after ligating the uterine artery without undue tension, it should be so included, securing the ligature from slipping by taking a turn around the infundibulo-pelvic ligament. When the ligament is in place ready to be tied the forceps should be removed from it and the ligature firmly tied, with a treble knot, and forceps attached to the pedicle outside of the ligature. The opposite side is treated in the same manner.

Everything is now finished about the pedicle except

closing the peritoneum over the stump. This is accomplished by stitching together with a running suture of antiseptic catgut the two edges of the peritoneum which was stripped off the anterior and posterior surfaces of the uterus before amputating the uterus. When this is done the pelvic peritoneum is perfectly closed, and as soon as the toilet of the cavity is completed, the abdominal wound should be sutured, the dressings applied and the patient put to bed.

Remarks.—The Trendelenburg position may usually be used with advantage immediately after the uterus is amputated in order to expose the bottom of the pelvis. Some operators place their patients in this position from the beginning of the operation. Drainage is not necessary after a normal case.

COMPLICATED CASES.

Unfortunately in the surgery of fibroid tumors uncomplicated cases are not the rule. The most common anomalies are the following: 1, pedunculated tumors; 2, tumors developed into the broad ligament; 3, interstitial tumors involving the cervix; 4, tumors complicated with diseased appendages; 5, suppurating fibroids; 6, tumors complicated with pregnancy; 7, extra-peritoneal fibroids.

1. *Pedunculated Tumors.*—Tumors of varying sizes with small pedicles are occasionally found growing from some portion of the uterus. If they represent a distinct tumor and the uterus is not involved with separate or other centers of fibroid development, and the appendages are not involved, the operator should seek to remove the tumor without interfering with the uterus proper. In order to accomplish the removal of these pedunculated masses, and secure a pedicle which may be safely dropped a definite line of procedure should be followed. If the tumor is only partially pedunculated so that a portion of its bulk is buried in the uterus necessitating enucleation, I prefer to remove the uterus, as I consider that the only absolutely safe procedure under the circumstances. If the tumor, however, is pedunculated, so that a pedicle of peritoneum, connective tissue, and the blood vessels feeding the tumor, without tumor tissue or uterine tissue, can be secured after its removal, I do not hesitate to ligate and drop the pedicle any more than I would hesitate to drop the pedicle of an ovarian cyst.

Method: The tumor is delivered. A pair of strong hemostatic forceps is clamped on the pedicle between the tumor and uterus, unless the tumor encroaches upon the pedicle too much to make a clamp effective after the growth has been enucleated, when instead of a clamp a provisional rubber ligature should be used. The tumor should now be cut away. If the pedicle is long and not involved by the tumor it should be severed close to the tumor, thus leaving abundance of tissue external to the clamp. If the pedicle is short and encroached upon by the tumor, the incision should extend around the base of the tumor at a distance of at least two inches from the provisional rubber ligature, involving the peritoneal coat and connective tissue capsule of the tumor (the pedicle edges of the incision being caught on three sides by hemostatic forceps to control the stump and prevent slipping of the ligature), and the tumor is enucleated, leaving a pedicle of connective tissue, blood vessels and peritoneum.

The pedicle is treated in both cases alike. If blood vessels of considerable size are found in the free end they should be ligated separately close down to the

provisional clamp or ligature. Then a strong antiseptic catgut or silk ligature should transfix the pedicle near its edges, and, after tying the first knot the provisional clamp or ligature should be removed and the ligature securely tied, so as to secure every portion of the pedicle. If care has been observed to eliminate all uterine or tumor tissue from the pedicle it will be as secure now as an ordinary pedicle of an ovarian cyst. The pedicle should be trimmed down to within an inch of the final ligature.

The writer has removed two pedunculated fibroids of large size in this manner, one of ten pounds and another of eight pounds, in which pregnancy existed, the women both going on to term afterward and giving birth to their children without complications. One of these conceived afterward. Another case of this kind in which a tumor of large size was removed, afterward conceived and gave birth without complications to a living child.

2. *Tumor developed into the broad Ligaments.*—It is not a rare complication to find these tumors of the uterus developed in the folds of the broad ligament to such an extent that the ligament is spread out over the growth and its folds tense. Frequently it will be impossible to deliver the uterus until the portion has been enucleated from the broad ligament. The line of procedure here is: First, enucleate the tumor from the broad ligament, and second, deliver the uterus as in uncomplicated cases and complete the toilet in the same manner.

First step: Tie if possible the ovarian artery near the outer edge of the tumor near the pelvic walls. If more convenient a provisional forcep may be used to secure the vessel.

Second step: Split the tense peritoneum which represents the broad ligament, the folds of which have been eradicated by the burying tumor, by drawing a scalpel over it at its most prominent point in a direction from the uterus to the side of the pelvis. Then with the fingers or some blunt instrument the tumor is gradually peeled from its subperitoneal bed, constant traction being exerted on it until the uterus and tumor are delivered.

Third step: Completion of the operation as in a normal case.

3. *Interstitial Tumors involving the Cervix.*—When the fibroid has developed low in the substance of the uterus so as to occupy the cervix, some management is required in order to secure a proper pedicle. Two methods may be pursued; first, complete enucleation of the fibroid tissue from the cervix, and second, complete removal of the cervix.

When it is possible, I prefer to enucleate the tumor from the cervix in order to preserve that portion of the uterus for a pedicle and a key to the abdominal floor.

The first part of the operation is conducted as in a normal case or if any portion of the tumor is subperitoneal as in the last method described. When the region of the large cervix is reached, a blunt instrument should be employed to completely enucleate it from all surrounding tissue, the bladder in front and all lateral tissue in order to insure perfect security of the ureters. This can only be done by keeping the point of the enucleating instrument well against the uterine tissue. If there is difficulty in securing the uterine arteries definitely, because of the necessary distortion of the tissues, two strong Tait pedicle-pins should transfix the cervix, at right angles to each

other, their ends being supported by the abdominal walls, and beneath these a provisional rubber ligature should be placed. The tumor is then cut away, down to the pedicle-pins, and the uterine arteries are sought and tied. After insuring hemostasis, the elastic ligature is removed and the fibroid tissue of the cervix carefully peeled out of its capsule. From this point the case is treated as a normal hysterectomy.

Removal of the cervix: Occasionally it may seem best to remove the entire cervix when it is the seat of the fibroid invasion. The same course should be pursued here as when the cervix is to be retained. The uterus may or may not be severed above a provisional elastic ligature, before ligating the uterine arteries. When the cervix has been thoroughly stripped and the vagina rendered aseptic, the vagina should be opened at the anterior or posterior cul-de-sac close to the cervix, and one blade of a curved pair of scissors slipped through into the vagina, and the cervix completely severed from its vaginal attachment by following the circumference of the cervix with the scissors. A guide in the vagina in the form of a staff may be employed in making the first vaginal incision. If there are any small bleeding points on the vaginal edges they should be tied with catgut or twisted with hemostatic forceps. The vagina should be loosely packed with sterilized iodoform gauze from above so as to just reach to the upper end of the severed vagina. The tissues in the bottom of the pelvis naturally fall together. With abundant drain in the vagina I simply allow the upper end of the vagina and the other severed tissues to fall together naturally, contenting myself to close the peritoneum alone with a running antiseptic catgut suture, exactly as when the cervix is allowed to remain.

4. Tumors complicated with diseased Appendages.—Diseased appendages are a frequent accompaniment of fibroids of the uterus. When fibroids demanding a hysterectomy are complicated with diseased appendages the disease of the adnexia should be treated in the ordinary way, and then the hysterectomy should be carried out on the lines best suited to the case.

Cysts of the ovary, without adhesions, scarcely complicates a hysterectomy for fibroids. The pedicle of the tumor is at once ligated with strong silk or clamped with strong forceps and the tumor removed. If it is of considerable size it may first be emptied with a trochar.

Pyosalpinx should be attacked as though no fibroid existed. If there has been bilateral disease of the appendages with extensive peritonitis and numerous adhesions, the adhesions should be carefully separated and the diseased pus tubes and ovaries carefully enucleated and removed. Then the uterus is removed in the ordinary way. The matter of drainage should be dealt with here exactly as when no hysterectomy follows, except that it may oftener be more convenient to drain through the vagina. If enucleation of the appendages has been such that large peritoneal adhesions have been separated and there is considerable unavoidable oozing from raw surfaces, some form of drain is imperative. As the most dependent portion of the pelvis is Douglas's cul-de-sac, one should select that point from which to make vaginal drain. Fig. 3 crudely represents an instrument I have devised for opening the cul-de-sac and guiding my drainage gauze into the vagina. The lower instrument (b) represents a staff which is placed in the vagina as a guide, with a tubular end which will act as a counter pressure for the

pointed dressing guide which penetrates the cul-de-sac from the pelvic cavity. The upper instrument is a hollow forceps with pointed blades, which when they have penetrated into the vagina guided by the staff are opened and a strip of gauze of any size may be pushed between them and drawn through from below. The tubular forceps may also act as a guide for a rubber drainage tube. Those who have attempted to place drainage tubes or gauze without a proper guide will appreciate the advantage of this instrument.

So after the uterus is removed a roll of sterilized strip gauze about the size of the index finger should be drawn through the cul-de-sac into the vagina, the vagina loosely packed with gauze below and a packing left in the lower part of the pelvis sufficient to take care of any oozing from the peritoneal surfaces, Fig. 4. The toilet of the peritoneum is completed as in ordinary cases and the abdominal wound closed. The dressing used as a drain is removed as soon as it no longer soils the dry dressings which are placed in contact with it at the vaginal outlet, usually from twenty-four to forty-eight hours.

5. Suppurating Fibroids.—Infected fibroids in which there is extensive interstitial suppuration are extremely rare. I have not seen more than two such cases in my experience. One of these I removed. The tumor had been infected more than a year before I operated on it. Several abscesses formed at intervals in the interior of the walls of the large uterus

FIGURE 3.

and then discharged through the cervix. The case failed to successfully drain after several operative procedures which I attempted through the cervix. Finally I decided to do a complete abdominal hysterectomy, one which would also include the infected cervix. The operation is performed practically as described above for the complete removal of the uterus including the cervix. Extreme care must be maintained to protect the abdominal contents and peritoneum from the infected contents of the uterus. If the vaginal track is employed for drainage, it should be thoroughly cleansed first by a competent assistant who is not allowed to further participate in the operation. All drain gauze should be drawn from above downward, never the reverse.

6. Tumors complicated with Pregnancy.—Fibroid tumors of large size complicated with pregnancy demands the sacrificing of the product of conception and the removal of the uterus.

Symptoms: The symptoms of pregnancy are usually all present in an exaggerated form. Menstruation which has heretofore been excessive and frequent on account of the fibroid will cease abruptly. The tumor will begin to grow rapidly. Pressure symptoms are much exaggerated. The bowels and bladder will become crowded and sacralgia and dysuria will result. In a word, all the ordinary symp-

toms of growing fibroids of the uterus minus hemorrhage, and all the classical symptoms of pregnancy, will become magnified to a painful degree.

Pedunculated fibroids of the subperitoneal variety, with small thin pedicles complicating pregnancy may be removed in the manner described in this article under the head of pedunculated fibroids, without disturbing the contents of the uterus. If the tumor involves the uterine walls to any marked degree and the tumor is so large that it will prevent full development of the fetus or its development to the point of viability, or the tumor's position is such that it will interfere with the pregnancy taking its proper course, the entire uterus should be removed with the tumor, if it is considered necessary to remove the tumor at once. If pregnancy is known to exist before an operation is determined on for the removal of the tumor, as a rule it would be safer to empty the uterus as an early preliminary measure, if it is feasible, reserving the operation on the tumor for a time after convalescence from the abortion is accomplished.

Operation: However, if it actually becomes necessary to remove a fibroid uterus complicated with pregnancy, either as a matter of choice, or accident from

severed at its point of deflection from the tumor on to the parietes. The tumor should then be grasped with strong blunt toothed vulsellum forceps and while traction is being made to deliver the tumor the fingers should carefully enucleate the growth from its bed. Great care should be observed in order to enucleate it perfectly and free it absolutely from the ureters or the rectum walls. By following the enucleation the tumor will finally lead to its pedicle which will be the uterus. The cavity from which it is enucleated should be packed temporarily with sterilized gauze sponges in order to check serious oozing. When the tumor is finally enucleated and removed, together with the uterus, in the ordinary manner, the work of making a pelvic floor must be accomplished. If there is not peritoneum enough left to cover the floor of the pelvis and a large raw surface is inevitable, this should be drained into the vagina by a roll of gauze an inch in diameter with a packing in the pelvis sufficiently large to cover the denuded surface. Occasionally the cavity from which the tumor is enucleated may be packed with gauze and drained into the vagina as a subperitoneal pocket and the peritoneum closed over it. As a rule these cases require drainage.

SOCIETY PROCEEDINGS

Medical and Chirurgical Faculty of Maryland.

Abstract of the Proceedings of the Ninety-eighth Annual Session, Baltimore, Md., April 25 to May 1, 1896.

FIRST DAY.

DR. CHARLES G. HILL Presided; DRs. JOHN S. FULTON, ROBERT T. WILSON and W. G. TOWNSEND, Secretaries.

DR. CHARLES G. HILL delivered the address on the subject of
SOME OBSERVATIONS ON THE EFFECTS OF THYROID FEEDING
IN THE INSANE.

After referring to the literature on the subject he said he had used the treatment in forty cases, some of which were acute, some chronic and some in old persons. He had the following results: Unimproved 8, improved 12, greatly improved 14, cured 5, died 7. He then reviewed a few typical cases and spoke of the effects of the treatment in general. In some there was elevation of temperature, gastric disturbance and albuminuria.

DR. E. N. BRUSH read a paper on the

DIAGNOSIS OF INSANITY BY THE GENERAL PRACTITIONER.

He spoke of the ignorance of the average physician in matters pertaining to insanity. He said the laws of commitment varied in the different States; that in New York, Pennsylvania and Maryland a written certificate was necessary to commit a person to an insane asylum and two physicians were obliged to sign the papers. Some of the diagnoses were quite absurd. He divided the insane into two classes: 1, those due to inherent brain defects under which we class idiocy with certain degenerative forms of insanity, of which paranoia was the great type; 2, conditions due to the diseases of the brain or to disturbances of the physiologic function by disease of other organs of the body. Under the second head are included melancholia, mania, dementia and general paresis. It is difficult to get a careful and correct history of a case. Persons will deny any family taint and try to deceive the physician. The general practitioner is usually not skilled in asking such questions and may be deceived. Even where there is no hereditary history of insanity, the phthisic taint on one side and the neurotic on the other may produce insane offspring. It is well to learn as much as possible of the patient first before seeing him and then examine him afterward. An insane person is usually shrewd and crafty and the examiner must use tact. Note the patient's attitude. Is he ill at ease? Is he quiet? Examine the skin, tongue, eyelids, hair, etc. There is rarely a clear complexion in the beginning of insanity. Persons insane often give the most lucid and sane answers, and paranoiacs who act in the most intelligent manner, until their hobby comes up, are frequent.

DR. HENRY M. HURD said that the general practitioner was

FIGURE 4.

mistaken diagnoses, the operation is proceeded with exactly along the lines of an ordinary abdominal hysterectomy. As a rule under these circumstances, the broad ligaments are loose, and the uterus freely movable making a hysterectomy comparatively easy. Any complication should be dealt with as in ordinary cases.

7. Extra-peritoneal Fibroids.—It is not infrequent that one will find in multiple fibroids that one or several of the centers of growth have developed low in the pelvis and in their increase in size they have gradually elevated the peritoneum and grown beneath it until they have become actual extra-peritoneal growths. The degree of such complication vary much in different cases, from a small nodule growing beneath the peritoneum from the cervix to a tumor weighing several pounds elevating the peritoneum in an irregular manner and distorting all the organs of the pelvis.

Method of Procedure: These cases are all subject to removal if they are handled in the proper manner. They must be enucleated. The peritoneum covering the abdominal surface of the tumor must be carefully

not usually familiar with the technical terms of insanity. Another difficulty arises from the fact that many definitions of insanity are legal and not medical, and the mistake is that the physician tries to show that the patient is legally and not medically insane.

DR. LLEWELYS F. BARKER made remarks on "Some Aspects of the Study of the Human Nervous System with Particular Reference to its development." He spoke of the neurons and types of cells, and said that these cells were separate and yet connected in a way that was too complex to explain. The development of the nerve cells depends on simple mechanical principles. They grow out and send there branches in the direction of least resistance. The neuron is the morphologic and physiologic unit. The study of the nerve anatomy of recent years would necessitate a recast of our knowledge of this subject. There are four varieties of skin sensation, sense of pressure, heat, cold, and pain. There are also definite sense areas in the brain. The newborn baby has a cerebrum with no medullated fibers. There is a great field for investigation in nerve study with the microscope since the newer methods of staining have been introduced.

DR. G. J. PRESTON spoke of the great advances made in neuro-histology in the last ten years.

DR. J. D. BLAKE asked if the collateral branches of the axon were real branches or were they simply fibrillae passing down from the cell with the body of the axon for a certain distance and then branching off? He also asked if Dr. Barker had not said that the fibers in the pyramidal tract did not cross, how he explained crossed paralysis?

DR. BARKER replied that the lateral pyramidal tract does cross over but the direct tract does not.

DR. H. J. BERKLEY made some remarks on the "Physical Nerve Cell in Health and Disease." He explained the different shapes of the cells. Some were pyramidal, some like whetstones and others were irregular. The branches of these cells have small lateral branches. In poisoning from alcohol, ricin, etc., the nerve cells and branches show thickening.

DR. A. K. BOND asked how wasted nerve cells could be affected by the thyroid treatment in twenty-four hours.

DR. BERKLEY replied that the thyroid extract caused a congestion around the nerve cell and a temporary improvement. The nerve cell degenerates in a short time, and as it is a complete substance in itself it does not recover. He is not pleased with the thyroid treatment.

DISCUSSION ON DIABETES MELLITUS.

DR. WILLIAM H. WELCH in speaking of the pathology of this disease said that no lesion was universally present in diabetes; nevertheless it is hardly correct to say that there is no lesion characteristic. There is one which is pathognomonic, but it stands in no relation of cause and effect. It is constant in this disease and is found in certain cells in the kidney. Armani described it in Cantani's book about twenty years ago. It was supposed to be a dropsical affection, but now we know it is a glycogenic metamorphosis of the cells. The epithelial cells lose their clearness, but the nucleus is clear. This is found chiefly in the ascending arm of the tube. If the specimen is so prepared that the glycogen is still there it can be easily seen under the microscope. The specimen is put in boiling water, absolute alcohol or water with iodine. These cells are filled with glycogen, and in all cases which he has examined the glycogen is present. The diagnosis of this disease can always be made at the autopsy, but there is no reason to suppose that it is a cause, but more probably a secondary effect. The causal lesions which we know are of two classes, of the central nervous system and of the pancreas. Bernhard von Mering and others first described lesions in the medulla oblongata. These have been found in many cases. Bouchardat, Lancereaux, Frerichs and Senator, all understood this disease and antedated the experimental work, and, indeed, this was known in the last century. It is only in the last seven years that more attention has been given to the pancreas in this connection. The total extirpation of the pancreas in dogs has caused diabetes. This is not due to a lesion of the surrounding part, but to the interruption of the function of the pancreas. The proportion of cases of diabetes associated with pancreatic lesion is at least 50 per cent. The lesions of the pancreas vary in their character. Hansemann says that one lesion which is invariably associated with diabetes, is granulation atrophy of the pancreas. It has its analogy in the granular nephritis. There is an increase of the connective tissue, a thickening of the walls of the vessels and a diminution of the glandular substance. There is no other lesion which destroys the function of the pancreas that will cause it. Calculus of the duct and new growths may cause conditions almost similar. These facts may not be so reliable when we consider that the pancreas is

examined at the post-mortem in every case of diabetes, but is rarely looked at in other diseases. He holds that all cases of diabetes are due to changes in the pancreas. There is no characteristic lesion of the liver; indeed, it is not often affected at all. Some lay great stress on the dilatation of the blood vessels of the liver. This is not demonstrable and not important. In some cases the liver cells are changed and there is a glycogenic metamorphosis of the nucleus of the cells. He does not believe that the sympathetic nervous system has anything to do with the cause of the disease. There is some change in the blood. Glycogen has been seen inside the leucocytes. Diabetics are especially predisposed to complications, especially to infection from pyogenic organisms, boils, carbuncles, etc. Senator says that lobar pneumonia is a rare complication; Osler says that it is very common. Klemperer says that it is not common probably because the organism of pneumonia does not grow well in the presence of sugar, but Welch says, on the contrary, that the presence of sugar favors their growth. In these cases colon bacillus is found.

DR. JOHN S. FULTON then spoke of the etiology of this disease. When the food supply of carbohydrates is excessive the glycogen reservoir is overtaxed. If the ingestion of sugar goes beyond the physiologic line glycosuria appears for a short time. Heredity, age, sex, social condition, geographic position, race, contagion, temperament and certain diseases are all predisposing and determining causes of diabetes.

DR. WILLIAM OSLER then spoke of the "Varieties and Clinical History of Diabetes." Three questions are asked by the physician: 1. Has the patient sugar in his urine? He referred to a case of alkaptonuria. A man was rejected for life insurance because he was supposed to have glycosuria; further investigation of this case in 1887 showed the absence of sugar and the presence of a substance called alkapton. Dr. Osler had a case last year which was supposed to be diabetes; Fehling's and other tests showed the presence of sugar, but the fermentation test and polariscope showed that no sugar was present. This man also has alkaptonuria, and strange to say, was a brother of the first case referred to. 2. Is it true diabetes or is it a transient glycosuria caused by an excess of starchy food, by nervous trouble, or is it a toxic form of glycosuria? 3. Given a patient with diabetes, is it a mild or severe case? In a mild case all we have to do is to cut off the carbohydrates for three days and put the patient on an ordinary meat diet and the sugar will disappear in from one to three days. Most cases we see are in men between 45 and 50 years old. The disease can be controlled by diet. He gave instances in which an excess of starchy food increased the amount of sugar very markedly, but on a strict nitrogenous diet the sugar was kept within bounds and the man could follow his business. A case in which you exclude the carbohydrates for three days and the sugar still remains is a grave case. The disease runs a rapid course in children. Adults can stand it much longer and in exceptional cases they have been known to live many years with the disease.

DR. H. FRIEDENWALD then spoke of the "Ocular Manifestations of Diabetes." Diabetic affections of the eye are due either to general debility, to disturbances of the nutrition or to the production of the toxic substance in the blood. Visual disturbances are general enfeeblement depending upon weakness of the external ocular muscle and still more to the muscles of accommodation. The affections probably due to nutritive disturbances are cataract, retinitis and hemorrhages within the eyeball.

DR. T. C. GILCHRIST then spoke of "Cutaneous affections in Diabetes." In diabetes the skin is perhaps more affected than any other organ of the body. The most characteristic cutaneous lesions are found in the genital regions.

DR. I. E. ATKINSON then spoke of the "Prophylaxis and Treatment." From the variety of its pathology we would have no way of treating it etiologically. Measures for prevention can only be taken in a few cases. In hereditary cases, in obese and gourmandizing person and in those who have recovered from one attack we can take measures to prevent its recurrence. The medicinal treatment is unsatisfactory. Arsenic occasionally benefits. The latest remedy recommended by West of England is uranium nitrate, 20 grains three times a day. One drug, to speak of, is opium; it has very little influence over the disease, but it checks the glycosuria and polyuria. Codeia and morphia are the best forms to give opium. The habitual use of opium in this disease is not desirable. The suggested treatment with pancreatic extract is of no special advantage. The most satisfactory treatment is by diet. Diabetic patients are as untruthful as opium eaters and very little confidence can be placed in their word. Aleuronat bread and peanut flour bread have been highly recommended. Mineral waters are also used. He must have fat or alcohol to

make up for the loss. Never put the care of a patient in his own hands. He should have his food arranged for him so as to insure variety of diet.

DR. A. K. BOND said that diabetes in children was rapidly fatal and that treatment seemed to be of little avail.

SECOND DAY.

DR. R. PERCY SMITH then exhibited a patient who had a "Compound Fracture of the Skull with Loss of Brain Tissue." The boy had been kicked by a horse in the forehead. Dr. Smith injected nitroglycerin and gave digitalis. The boy's condition improved. He removed some bits of bone, treated the wound antiseptically, gave careful diet and the boy entirely recovered, with a loss of only one ounce of brain substance. The tablet of bone is still depressed.

DR. R. WINSLOW thinks there may be danger yet and that the bone ought not to be left depressed.

DR. J. C. HARRIS said that the injury was near the supra-orbital vessels of the nerves and an operation might be dangerous.

DR. SMITH said, in conclusion, that the family opposed an operation.

DR. L. M. TIFFANY then spoke of "Operative Measures for the Relief of Facial Neuralgia." He said one could not say what the result of the operation would be. Many operations are done with entire relief to the patient and little loss of power. There have been about eighty five to ninety-five cases recorded. The mortality was larger than was usually supposed. He had ten cases himself. One had died on the twenty-fifth day from sepsis. He had operated on one case twice; he had had cases in which the nerve and ganglion had both been removed and yet the pain remained. In one case the man had entire sensation in the skin of the forehead and yet his nerve was in a bottle. He has had no recurrence of the pain in any case. After section of the nerve and removal of the ganglion the sensation will gradually come back and the sense of heat and cold, but not motion and no pain.

DR. J. M. T. FINNEY referred to several cases, one got well, had a slight return of the pain, and one died the day of the operation.

DR. R. WINSLOW related a case of removal of the fifth nerve and its branches and a part of the nerve behind the ganglion, and now he has pain on the other side of his face and a double operation would cause paralysis of the muscles of mastication on both sides.

DR. I. R. TRIMBLE then related three cases of "Injuries to the Kidney with Surgical Treatment."

DR. RANDOLPH WINSLOW made some remarks on "Surgical Diseases of the Kidney."

DR. J. M. T. FINNEY spoke of the "X Rays in Surgery."

DR. HOWARD A. KELLY then made some remarks on the "Use of the Renal Catheter in the Diagnosis of Stone in the Kidney." He showed plates and explained how easy it was with his cystoscope and head mirror, with woman in the knee-chest position, to introduce the catheter into the bladder and into either ureter at will. The presence of stone in the pelvis of the kidney could be thus detected. He used a hard rubber bougie coated with dental wax, applied to the bougie by dipping it into the melted wax. He thus obtained a smooth, glistening surface which showed the slightest scratch from the stone. He sometimes found it better to add a little olive oil to the wax. He also used a catheter, coating its tip with wax except at the eye, through which he could draw at will fluid from any part of the kidney or ureter. He had made the diagnosis of stones in the kidney of many cases in this way and he showed several specimens. In introducing the bougie or catheter covered with wax, care must be taken that it does not strike the cystoscope or any other object which might scratch its surface and deceive the surgeon. He brought this before the society and hoped that no surgeon would attempt to operate on stone in the kidney in woman without first attempting a diagnosis in this simple way.

THIRD DAY.

DR. R. TUNSTALL TAYLOR read a paper entitled "Treatment of Lateral Curvature of the Spine." This was caused by faulty position. Cases come from long standing, carrying heavy school books, violin playing, sitting at school on improperly made chairs and benches and other causes. Too many physicians do not treat these cases at all, but turn them over to the instrument maker and to those using Swedish movement. He then gave directions as to exercise, gymnastics, class drills, baths, and showed the apparatus with plaster jacket for the correction of the various deformities and the strengthening of the muscles.

DR. W. S. HALSTED then made some remarks on the "Oper-

ative Treatment of Gallstones." The surgery of gallstones of the duct and gall bladder is still in its infancy. As in other branches in surgery the time will come when we will not operate at all for many conditions for which we do now. Langenbuch's idea was to extirpate the gall bladder, but this is not done often. Another operation soon to be given up is the Winiwarter's cholecystenterostomy. Another form of operation which has been abandoned is the two-act operation. At the first operation explore all the ducts if possible. It is not always easy to explore the cystic duct, but one can explore the common duct. It can be done by cutting through the mesocolon and drawing the omentum up and the duodenum out and the common duct will be seen. It may be necessary to excise the ends of the lower rib, but this is not desirable as the cut ends cause great pain. An osteoplastic operation might be an improvement. All the operations should be done at one sitting. Special needles for sewing up the gall bladder should be used. They must be small No. 12 to sew up the walls of the common duct. The walls are usually very thin, but when a stone has been there for years the walls are thicker. There is not much experience in common duct surgery. He related one or two cases. Not all cases need to be operated on, but it is well to operate before the stone gets into the common duct.

DR. S. T. EARLE then reported "Two Cases of Tuberculous Fistula in Ano," and his manner of operation, and his object was to show the importance of a microscopic examination.

DR. HALSTED said that he had never seen a case of primary rectal tuberculosis. He had seen cases of primary vaginal tuberculosis where the disease occurred nowhere else in the body except a beginning peritoneal tuberculosis. He had once an interesting case of laryngeal and pharyngeal tuberculosis which he had cured by cauterization of the mucous membrane.

DR. EARLE in 1884-5 had made 160 autopsies and had found no tuberculous ulceration of the rectum.

DR. H. H. BIEDLER then exhibited a case of "Trephining for a Local Paralysis with Cure." He had undertaken this operation with very little knowledge of the cause of the trouble and with little expectation of such good results.

DR. WM. S. THAYER then made some remarks on "Gonorrheal Endocarditis." Since Neisser in 1885 discovered the gonococcus many troubles which were formerly obscure had been now shown to be caused by this organism. There may be a pure infection or there may be a mixed infection or the gonococci may enter and make a way for other organisms, or pyogenic organisms may find their way in and drive out the gonococci. Also these local processes may be non-bacterial. He had seen at the Hopkins Hospital two cases of gonorrheal endocarditis, both of which died. In the first case the cultures were made from blood taken from the arm. From the growth obtained the gonococcus was suspected: in the second case it was found and examination of the blood and also of the clot on the valve of the heart verified the diagnosis.

DR. J. D. BLAKE then reported sixteen cases of "Laryngeal Croup treated by Intubation and With Antitoxin." The oldest was seven years, the youngest four months. Twelve recovered and four died. In one case the antitoxin was used on the second day and in another on the ninth. In two cases no organisms were found in the throat but they can carry contagion. He then showed a simple but very effective instrument for removing the tube.

DR. GEO. J. PRESTON then read a paper entitled "The Gastro-intestinal Manifestations of Hysteria." He first spoke of contraction of esophagus causing rejection of the food. Blood was often vomited: this was bright red in character and simulated other affections. Many cases of so-called vicarious menstruation were really hysterical. Hysterical anorexia was common, hysterical patients seemed to be able to live on very little food and often go an incredibly long time with little to eat. They will often attempt to deceive by starving in public and stuffing in private. They suffer greatly with distension of the bowels with gas.

DR. HEMMETER said this paper was read from the standpoint of a neurologist. All the symptoms related seem to come from the nervous system. Certain forms of these troubles are intestinal and are due to auto-intoxication.

DR. PRESTON replied that we can not classify the pathology of neuroses, hence we have to run the gamut of all the specialties. In so many cases we can find no evidence of a pathologic lesion.

DR. SOLOMON SOLIS-COHEN, of Philadelphia, in the evening delivered the annual oration. His subject was "The Path of Progress in Modern Therapeutics." After this the portraits of Dr. Geo. W. Miltenberger and Dr. H. P. C. Wilson were presented to the society with appropriate addresses by Dr. S. C. Chew and Dr. T. A. Ashby.

FOURTH DAY.

DR. JOHN C. HEMMETER then read two papers, one on the "Possibility of Intubation of the Duodenum," and the other on the "Effects of Persistent Intestinal Putrefaction Upon the Kidneys."

DR. JOSEPH T. SMITH then reported several cases showing the importance of a careful Examination of the Urine in Suspected Diseases of the Kidney.

DR. HEMMETER referred to the importance of examining the patient on both sides before any operative treatment on the kidney and referred to a case in which one kidney had been removed and it was found out afterward that it was the only kidney the man had.

DR. E. M. SCHAEFFER then read a paper entitled "The Physical Director of the Second and Nineteenth Centuries," and advocated a wider recourse to the natural therapeutics of the old Greek gymnasia or modern sanitarium.

DR. JOHN G. CLARK then spoke of "The Prevention of Thirst following Operations upon the Abdominal Cavity." Thirst is severe after operations, often as a result of the anesthetic. Many methods have been suggested, some to give water freely several days before the operation. He had tried enemata of salt solution, 0.6 per cent. immediately after the operation. By comparing patients treated in this way with those given no water the former were found to pass a larger amount of water the first three days while the latter the last three days, so that by the seventh day they had passed about the same amount. He finds the routine use of this injection of great use in preventing thirst.

DR. T. A. ASHBY then reported a case of "Accidental Rupture of a Pregnant Uterus: Hysterectomy; Resection of Eight Inches of Intestine: Recovery."

DR. J. W. WILLIAMS then read a paper on "The Frequency of Occurrence of Contracted Pelves in Baltimore," in which he reported the results of the measurement of 100 women. His conclusions from these studies were that the pelves of Baltimore women were much below the normal.

DR. THOS. S. CULLEN read a paper on "Adenomyoma of the Uterus."

DR. W. W. RUSSELL read a paper on "Post-operative Recurrence and Metastasis in Carcinoma of the Uterus."

Other papers were read by title.

Officers for 1896-7: President, Dr. Wm. Osler; First Vice-President, Dr. Wilmer Brinton; Second Vice-President, Dr. Randolph Winslow.

SELECTIONS.

Eucasin, the New Preparation of Casein.—Professor Salkowski of the Patholog. Institute, Berlin, announced a while ago that casein possesses all the nutritive value of albumin, while free from the disadvantages of the albumoses. He has recently been making a series of experiments on dogs with it in the form of a readily soluble powder, the eucasin prepared by Majert and Ebers of Grunau, accompanying a diet of bacon and rice. He found that from 95 to 98.84 per cent. of the nutrients were taken up by the organism, with corresponding increase in weight and general improvement, with no deleterious results. He also experimented with the recently lauded somatose at the same time, but found that only 60.49 per cent. of the nutrients were taken up in this case. The animal also had diarrhea and grew thin on somatose. He put the same animal afterward on the eucasin, when health and spirits revived and the animal gained 410 grams in the two weeks of the experiment. A two days' experiment on a healthy young man also showed a similar large percentage of nutrients retained in the organism. The details of the experiments are given at length in the *Deutsche Med. Woch.*, April 9. Salkowski recommends eucasin therefore to the profession as a most valuable article for nutritive purposes stirred into soups, etc., and especially indicated in arthritic cases or wherever there is an excessive secretion of uric acid, as there is no nuclein in casein as in albuminous substances.

Bacteruria Complicating Gonorrhea. This disorder requires special treatment, and yet it is often neglected, as the symptoms are apt to be misunderstood. It is caused by an invasion of the bladder, urethra or prostate gland by coli bacilli, flourishing in the lesions of the gonorrhea, even after the gonococci have disappeared. The urine has a milky appearance, with a

peculiar odor different from the ammoniac odor of an ordinary cystitis. If the infection is located in the prostate, the disturbance of the urine is intermittent and occurs especially after defecation. If the patient urinates then into three receptacles, the first will contain the traces of gonorrhea, the second may have globules of pus, and the third will be distinctly milky, owing to the coli bacilli forced out by the contraction of the peri-prostatic muscles. Bacteruria is usually accompanied by general symptoms and a special urethral discharge, appearing suddenly, perhaps long after the other discharge has ceased. It resists all the usual gonorrheal remedies, an important point in diagnosing. If the bladder only is involved, a cure will usually follow instillation of nitrate of silver into the bladder, preceded by copious irrigation with boric acid water. If the prostate is affected it must be treated manually through the rectum, the prostatic end of the urethra cauterized and salicylic preparations administered internally. The prognosis in such cases is doubtful, and if there exists any communication between the prostate and the rectum, it is absolutely unfavorable. The bacteruria alone need not prevent matrimony, as there is no record of its transmission in this way.—Schlifka, Vienna, in the *Semaine Médicale*, April 1.

Warm Baths in Diffuse Bronchitis in Children.—Renaut has been treating for ten years those forms of bronchial catarrhal inflammation involving the entire bronchial system except the bronchioles, with systematic warm baths, according to Brandt's method. He has treated over a hundred cases and has not seen a single case develop capillary or fatal symptoms. Whenever the rectal temperature, taken every three hours, reaches or passes 102, he proceeds to put the child in a bath at 101.5, leaving him in the water seven to eight minutes, keeping the head wet with water at the temperature of the room. When the child is over 2 a little champagne or brandy and water is given in the middle of the bath, and he is wiped rapidly with hot towels. The bathing is to lower the fever and prevent the toxic thermogenetic effects, and would be as beneficial for adults if they could be lifted and handled as easily as children. Renaut gives at the same time quinin in suppositories, 15 centigrams of the sulphate, or better still, the hydro-bromid of quinin, morning and evening, under 2 years, increasing with age up to 25 centigrams for a young adult, continuing it several days after the fever has subsided. If called late in the case ipecac may be needed, but Renaut exclaims: "Never a particle of antipyrin or anything of the kind. They may produce a deceptive improvement, but it is merely superficial and weakens the very organs most needed." The only objection to this treatment is the protests of the family, but Renaut refuses to consider this, merely suggesting that the physician superintend the first bath himself.—*Bulletin de l'Académie de Médecine*, March 24.

The Causation of "Schluck-pneumonie."—In the recent discussion before the New York Academy of Medicine on the apparent increase of deaths by pneumonia, in diphtheria, since the introduction of the antitoxin treatment, and the use of the above term was heard by many for the first time. In a recent issue of the *London Lancet*, the etiology of this affection is discussed as follows: "'Schluck-pneumonie' and 'Inhalations-pneumonie' are terms used in Germany to denote that variety of pneumonia which is in most cases brought about either by the inhalation of septic particles originating in disease of the mouth or tongue or by the accidental entrance of foreign matter, such as particles of food, into the air passages. It may also follow surgical operations on the mouth. In Professor Gussenbauer's wards Dr. Kneibich has examined twenty-eight cases, comprising twenty of 'Schluck-pneumonie' and eight of lobular pneumonia, in which the origin by inhalation was not satisfactorily made out. *Diplococcus pneumoniae* (Fraenkel-Weichselbaum) was found in twenty-three cases, and in fourteen of these a typical *diplococcus pneumoniae capsulatus* was present. *Streptococcus pyogenes* was observed in three cases, *staphylococcus pyogenes aureus* in four, *micrococcus pneumoniae* in three, *bacillus pneumoniae* in two, *bacterium coli* in seven, and *sarcina* in one. Broncho-pneumonia, and especially 'Schluck-pneumonie,' are due to the *diplococcus pneumoniae*, but the *bacterium coli* may also give rise to lobular pneumonia in man. After the inhalation of the septic matter the *diplococcus* sets up pneumonia and the bacteria penetrating with the *diplococcus* into the bronchial ramifications, but not into the pulmonary tissue, produce toxins by the continuous irritation of which the exudative inflammation is changed into induration."

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, MAY 16, 1896.

THE ATLANTA MEETING.

There have been few meetings in the history of the ASSOCIATION which have passed off more harmoniously and more pleasantly in all respects than that just concluded at Atlanta. In other columns we publish the minutes of the meeting, from which details of the routine proceedings will be seen, and the papers will be published in full as fast as possible.

The selection of Philadelphia¹ as the place of the next meeting (which was originally suggested by DR. S. C. BUSEY of Washington in a letter to the JOURNAL last year) was made by acclamation. Both the President and first Vice-President were elected without a ballot, and there was no particular friction or trouble in the election of other officers.

We might add in this connection that the record showed it to be about the first time in the history of the ASSOCIATION that the report of the Trustees was received without criticism or adverse comment, and it may be said truthfully that unity prevailed on nearly all questions, except the perennial one of change of Secretary.

The places of meeting provided for the Sections, at Atlanta, were ample and easy of access, and the papers read at the meeting (as may be seen by the program) were of exceptionally high order.

The election of PROFESSOR SENN to the Presidency, was a proper recognition of his scientific attainments and great contributions to surgery; while that of GENERAL STERNBERG to the position of Vice-President, was in the same way a testimonial to his vast erudition and scientific ability, and those selected to give the annual orations—FLINT, KEEN and COCHRANE—are respectively at the very head of the branches on which the address will be delivered.

Socially, the Southern hospitality which is always conspicuous at these gatherings, made itself felt in such a way as to make every delegate feel at home. The visit to the charming home of the THOMPSONS at Brookwood, the Georgia barbecue, and the receptions at the houses of DRs. CALHOUN, RIDLEY and TODD, are occasions to be long remembered. Indeed, if there is any criticism it is that DR. WESTMORELAND and the committee of arrangements and citizens did too much to make the visit of the members agreeable and pleasant.

Truly, the forty-seventh annual meeting of the ASSOCIATION should be marked with a white stone, as one of its *Dies Memorabiles*.

¹The origin of the ASSOCIATION is as follows: The New York State Medical Society, in February 1846, appointed 16 delegates to attend the proposed convention and accepted the invitation of the Faculty of the New York University to hold the convention in their college. The convention met in New York, May 5, 1846 with 119 delegates present. The convention then resolved to institute a National Medical Association, which was held in Philadelphia in May 1847. A constitution was adopted and the name AMERICAN MEDICAL ASSOCIATION chosen. N. S. DAVIS, now of Chicago, then of New York, is the originator of the plan.

VITALITY.

The question of a vital force is an old one that up to within a few years back was considered by the average follower of the physiologic leaders as one that was unworthy of serious scientific discussion. It was largely the fashion to treat all vital phenomena as manifestations of what must be some form of chemic or physical action, mainly, it would appear, on the assumption that it could not possibly be anything else. It was often confidently claimed that physics and chemistry would yet reveal all the secrets of vitality, and that to acknowledge anything special and mysterious, such as an unknown and possibly unknowable vital force or principle, was unscientific and reactionary. Within the last ten or twelve years, however, there has been a rather marked change in the general trend of views on this subject, as has been pointed out by DR. MCKENDRICK, and vital processes are recognized as supplementing chemic ones. This movement is at present led by some of the ablest of physiologists and physicists, and LUDWIG and HELMHOLTZ, who with others were largely responsible for the common rejection of the "vitalismus" doctrine, lived themselves long enough to see the reaction from the tendencies of which they were, in a sense at least, to some degree the originators.

At the present time biologists are actively speculating upon the properties of matter which are due to what we call vitality. They recognize this last as a fact, but can only offer theories to explain some of its workings; its peculiar essence is beyond their comprehension and may always remain so. Why matter at one moment should possess a certain something which we call life, which endues it with properties

and capacities that are clearly above and to some extent subversive of chemie and physical laws, and then at another moment, without manifest change in composition, be deprived of these endowments, is and possibly always will be a mystery.

The assumption, however, of a special vital "force" is uncalled for, unless we are to understand by the term force something differing from everything else to which the word is applied. Vitality is not convertible itself into motion or correlated with any of the physical forces, mechanic, chemie, thermic or electric, but overrides and controls them in what we know as living as distinguished from dead matter: no chemie or physical laws can account for the processes in the simplest living cells, much less the possibilities of heredity in the spermatozoön or the ovum. We can perhaps speak, as does MINOT in the latest issue of the *North American Review*, of a "special vital power which is not necessarily identical with any form of physical energy, though it may be conceived to cause the transformation of energy," but that is an entirely different thing from calling it a force in the legitimate signification of the term. It would be better to adopt the name "vital principle," which was a favorite term of the late PROF. JOSEPH HENRY, one of the most prominent physiicists of his time, thoroughly competent to give the limitations of the term force as properly understood, and also a believer in the reality of the distinction of vital from physical and chemie processes. The term certainly better expresses the relations as they exist and leaves us sufficiently uncommitted and free to accept any future, more positive knowledge that can be gained. It is at all events safer and less presumptuous to admit that there is a vast field that remains beyond our ken and power of comprehension in the commonest physiologic processes, than it is to attempt to extend the known laws of matter into and over the unknown and possibly the unknowable. And with the apparent present tendencies of physiologic thought, it would seem possible that those who still make such assumptions will be soon considered as decidedly behind the times.

TREATMENT OF GOITRE BY THYROID EXTRACT.

An important paper was recently read before the Berlin Medical Society by DR. STABEL on the above treatment in eighty-three cases. As reported in the *Medical Press and Circular* the writer stated that these cases were treated partly by fresh glands and partly by tablets from the Dresden Hofapotheke. Of the cases treated by the fresh glands, only twenty-five were brought forward, as only those cases that remained four weeks under treatment were made use of in the paper. For determining the size of goitre a measurement was made at the level of the vertebra prominens. The dangerous symptoms attributable to thyroid feeding were due to decomposition of the

gland. Although the glands were employed fresh, in the warm weather changes set in very rapidly, and sometimes gastric disturbances were produced; these symptoms did not come on when a better means of preservation was adopted. BAUMANN had succeeded in isolating the active part of the thyroid substance, had found it associated with iodine, and given it the name of thyroïdin. In all the twenty-five cases of feeding with fresh substance a positive result was obtained, but in almost all of them it was to the extent of considerable improvement. A cure or total disappearance of the goitre was only obtained in four cases. Two cases only could be considered as permanently cured: 8 per cent. of the cases, therefore, were cured, and 92 per cent. improved. The cases considered to be cured had remained well nine months. The amount of diminution in size brought about by treatment was not kept up after the treatment was stopped, but a gradual enlargement again took place.

A slight acceleration of the pulse was almost constant. In struma it was never necessary to stop the treatment on account of the increased pulse rate. Dangerous symptoms were never observed. In slighter cases, especially in young girls, a slight loss of weight was observed. A large number of cases were treated by tabloids when feeding with fresh substance was stopped, and in these the struma never increased in size in consequence of the change. In many a slow diminution took place. The results of the treatment by the Dresden tabloids were not so good as when the fresh extract was employed, the reason being that so large an amount could be given without threatening symptoms supervening. Three tabloids was the maximum dose given, in seven days, therefore, only three grams of the active substance could be given, whilst with the fresh substance five times as much could be given. The tabloids, in addition to being less active, had a much more unfavorable influence on the heart. The medicine had to be interrupted on account of increased cardiac activity caused by them. Especially in chlorotic and neurasthenic girls threatening symptoms supervened: acute dilatation of the heart was never observed under these circumstances. If the heart's action was once accelerated, this effect was kept up for weeks together. The tablets ought not to be articles of trade; cases were increasing in which they had a disastrous effect. A man aged 50, who was taking them for obesity, was suddenly attacked with a psychosis with a delusion of persecution, and died in a few days with cerebral edema.

The assumption appeared justified in this case that intoxication has been produced by the tablets, and the more so, as the speaker had observed three similar cases where delusions of persecution had also occurred. He added also three cases of morbus Basedowii treated as out-patients. Two soon ceased attending, as the nervous symptoms grew rapidly worse. In one patient vomiting came on and lasted a week, with great prostration and the symptoms returned three months later, when the treatment was recommenced. The second patient attended MIKULICZ'S klinik, where she was given thymus extract to loss of consciousness and maniacal attacks, and in this condition was brought back to Berlin. The third patient was treated with large doses for three months—three to four grams daily. No change had been observed, however, although a subjective improvement took place. Seven cases of morbus Basedowii had been treated with tablets, but even with large doses no other result had been obtained than an accelerated pulse up to 116 and upward. In the older cases with exophthalmus the nervous symptoms got rather worse than

better, and the ocular symptom was not affected. The treatment was directly contraindicated in Basedow's disease on account of the effect on the heart. In one case of vascular goitre with edema, swollen pendulous lips, etc., considerable improvement took place. The goitre became smaller, and no souffle could any longer be heard. In fourteen days she looked quite different, the face had become quite youthful, she felt quite well and could work hard. Subjectively she was quite contented and the struma had quite disappeared. One hundred and forty days after the treatment was stopped she returned on increasing size of the neck. Rapid effect was produced by thirty tablets daily, but the symptoms returned when the medicine was left off.

In the discussion of this subject continued to a subsequent meeting of the society, some more favorable results were reported, one of which was a patient of DR. SILEY. This patient was first treated in SENATOR's clinic with arsenic, but without result. The patient got worse from week to week although she was sent away into the country. On coming home again she showed all the symptoms of the disease, GRAEFE's sign, exophthalmus, trembling of the hands, and she could only drag herself up the steps with difficulty. A lady made her a present of three boxes of German thyroïdin tablets, of which she took six tablets a day. Although attending the polyclinic occasionally, she continued taking the tablets on her own responsibility, and at the present time, after about four months of the treatment, she could be pronounced nearly well. The circumference of the neck was reduced from 35 to 33 cm., the cardiac murmur had disappeared, and scarcely any trembling remained. It had to be looked for carefully before it could be noticed. The subjective condition was good.

DR. EWALD remarked that DR. SILEY's experience did not stand alone. A number of such cases had been described, especially in English literature. The majority of the observations were, however, unfavorable. He himself had seen no good results. In his case related at the last meeting the symptoms returned in an exaggerated form, and the thyroïdin was no longer of any use.

THE RESPONSIBILITY OF SEXUAL PERVERTS.

The question of responsibility of sexual perverts has been raised in our courts on various occasions within the past few years and has figured in several rather notable cases. That of ALICE MITCHELL, a few years ago, and the more recent one of GUY OLMSTED in Chicago, which has been written up by HAVELOCK ELLIS and TALBOT in the *English Journal of Mental Science*, are instances. When such a case is for any reason, the circumstances of the crime, the social position of the offenders, etc., prominently brought before the public attention, the question of insanity is likely to be raised, and it is a matter of some importance that prejudice and misinformation should not cloud the judgment and work against the interests of justice and the public welfare. With the

partial enlightenment, the little dangerous knowledge that leaks into the minds of the laity from the modern publications on the subject—there is altogether too much opportunity for the spread of misleading ideas.

No alienist will deny that sexual perversion may be entirely pathologic, and that it may entail a greater or less degree of irresponsibility for the aberrant and criminal acts it induces. To extend this however to all these acts or to create a presumption of irresponsibility from the acts themselves is carrying the theory altogether too far into practice and is liable to pervert justice and tend to a demoralization of public opinion. Even with those morbidly constituted individuals who are originally or congenitally aberrant in their sexual impulses, provided intellect, will and ability to recognize moral distinctions exist, there is no need of admitting entire irresponsibility. They are unfortunates to a certain extent, but there is no legal or moral reason why they should be permitted to indulge with impunity in acts that are contrary to good morals and that the public conscience condemns. Even when they are proven to possess the evidences of physical degeneracy, or even a family history of abnormal tendencies or insanity it does not necessarily follow that they themselves are absolute victims of their morbid constitution or heredity, though these facts when sufficiently pronounced may sometimes raise a reasonable doubt in favor of their irresponsibility. There is no normal appetite, however, that is more readily perverted than the sexual one, and the necessary organization of society and the restrictions placed upon its normal gratification are themselves often the cause of its abnormal tendencies with a certain proportion of those who indulge in them. Vicious education and associations are also responsible for a proportion, and abnormal sexual gratifications are the last resource of exhausted debauchees for whom the normal indulgence has lost all its satisfaction. According to JEANNEL, and others who have investigated the matter, they are almost invariably practiced by prostitutes, who belong more properly to the criminal than to the degenerate class in any normal social classification. In certain ancient civilizations and many modern barbarous peoples they have been or are customary and not considered reprehensible, and there is no good reason why their occurrence should be among us reckoned as a *prima facie* evidence of mental abnormality and consequent irresponsibility, as seems to be sometimes the tendency. It is carrying theory a little too far to assume the fact of the commission of a certain class of crimes, as evidence in itself of criminal incapacity and irresponsibility. With this as with other criminal acts for which irresponsibility is plead, each case must stand for itself and all the evidence of morbidity must be considered; previous record and character, associations, habits, as well as the family history and the mental and physical stigmata of degeneracy. Sexual

perversion may be a symptom of senile dementia, or of congenital or acquired mental weakness, but it often is only an indication of prolonged vicious habits and associations.

There is another aspect of the case that has been treated of in a recent article by DR. ALLEN McLANE HAMILTON (*Am. Journal of Insanity*, April, 1896) viz., the civil responsibility of sexual perverts. He shows how, in certain cases, homosexual attachments may lead to serious property complications, or to blackmailing operations of a peculiar kind. There are many instances of these and he reports some striking ones. Civil and criminal responsibility are not altogether equivalent and one may exist where the other is absent or impaired. The question of undue influence over a weak or defective individual is an important one as is also that of blackmail, and the morbid attachments that are free from actual sexual crime may yet figure in the courts in this connection.

The division of sexual perverts by DR. HAMILTON into three classes seems to be a correct one. He recognizes, first, those in whom the condition is connected with or a result of insanity, where loss of power of restraint exists, with consequent irresponsibility; second, those in whom it is simply a vice, and who are responsible, and third, those with whom it is the result of a more or less defective or erratic organization, but whose responsibility is a question that must be decided, as to its existence and degree, in each individual case. The first and second of these two classes are legally recognized and each is apt to be over-estimated according to the predilections and point of view. The last is too generally legally ignored or unrecognized although it probably forms a not inconsiderable proportion of the whole of this type of offenders against law and morality. And entirely apart from the criminal side of the question, there is much force in DR. HAMILTON'S view that homosexual attachments carried to the point that some of them are, afford a strong presumption of a state of affairs that "greatly militates against the proper exercise of free disposing and contracting power," and should, in the interest of families and heirs, be legally broken up, even if commitment to some restraining establishment is necessary for the purpose.

VIVISECTION IN CONGRESS.

Notwithstanding the protest of the AMERICAN MEDICAL ASSOCIATION and numerous other medical and scientific societies, the Committee on the District of Columbia has reported a bill to restrict vivisection in the District of Columbia. SENATOR GALLINGER (homeopathist) of New Hampshire, who has charge of this matter is on record in favor of absolute prohibition and will probably push it to a final consideration. The time has come, therefore, for the profession throughout the country to awaken to the gravity

of the occasion. It must act and act speedily. No one should delay for a single day to file his individual protest with the Senators and Representatives from his own State.

In our minutes of the ASSOCIATION meeting the resolutions of the ASSOCIATION will be found, clearly setting forth the opinion of the great representative body on this subject.

ASSOCIATION NEWS.

AMERICAN MEDICAL ASSOCIATION.

OFFICIAL REPORT OF THE PROCEEDINGS IN GENERAL SESSION, OF THE FORTY-SEVENTH ANNUAL MEETING, HELD IN ATLANTA, GA., MAY 5, 6, 7 AND 8, 1896.

MAY 5—FIRST GENERAL SESSION.

The Association met in the Grand Opera House, and was called to order by the President, DR. R. BEVERLY COLE, of California, at 10 A.M.

He was supported by Vice-Presidents, DRs. J. C. LEGRANDE, Alabama; A. P. CLARKE, Massachusetts; T. P. SATTERWAITE, Kentucky. The permanent Secretary, DR. WM. B. ATKINSON, Pennsylvania; Assistant Secretary, J. MCFADDEN GASTON, Jr., Georgia, and the Treasurer, HENRY P. NEWMAN, Illinois, were present.

Prayer was offered by the Rev. Dr. F. McDonald.

DR. FRANK M. RIDLEY, of LaGrange, Ga., delivered an Address of Welcome on behalf of the medical profession, and the Hon. John Temple Graves one on behalf of the Governor and the people of Georgia.

The Chairman of the Committee of Arrangements, Dr. Willis F. Westmoreland, of Atlanta, then announced the invitations and entertainments that would take place from time to time during the meeting. He also offered the official program of the meeting and its sections as the report of the Committee.

The President then delivered the Annual Address, which was punctuated with applause throughout its delivery. (See JOURNAL, page 889.)

The permanent Secretary announced the presence of Professor J. P. Remington, and Mr. F. W. E. Stedam, of Philadelphia, as delegates from the American Pharmaceutical Association, and, on motion, they were accorded the privileges of the floor.

DR. H. A. HARE, of Philadelphia, Chairman of the Committee on Business, asked that the several sections appoint temporary members to represent them in that Committee in the absence of the regular members.

By request of Dr. I. S. Stone, of Washington, D. C., the permanent Secretary read preamble and resolutions adopted by the Medical Association of the District of Columbia relative to a bill before Congress to prevent the practice of vivisection in the District, and, on motion, the President appointed a Committee of five to consider the communication and report on Wednesday.

The President appointed on this Committee Drs. N. Senn, of Illinois; J. McFadden Gaston, Sr., Georgia; Wm. Osler, Maryland; Geo. M. Gould, Pennsylvania; and Roswell Park, New York.

DR. H. O. MARCY, of Boston, moved that Thursday afternoon be devoted to the carrying out of the program of the Jenner Memorial Committee.

The President having invited Dr. Marcy to talk from the platform, Dr. C. A. L. Reed, of Cincinnati, rose to a point of order that the rules did not allow speeches from the platform.

PRESIDENT COLE decided this out of order, saying it was his prerogative to invite a speaker to the platform.

After some discussion, Dr. Westmoreland rose to a point of order, saying that this (Dr. Marcy's) motion was not in order as it had been arranged for.

The President decided it in order.

After further discussion, on motion of Dr. C. H. Hughes, of St. Louis, it was agreed that the Jenner program should be pursued on Thursday morning after the regular order of business.

The Chairman of the Committee of Arrangements presented a number of members by invitation, who were then elected.

DR. C. A. L. REED, of Cincinnati, offered the following:

Resolved, That the Committee on Nominations be and is hereby instructed to report to the general session on Thursday a list of delegates

to represent the American Medical Association at the Second Pan-American Medical Congress, to be held in the City of Mexico, Nov. 16, 17, 18 and 19, 1896, providing that the delegates thus chosen from any State or Territory shall not exceed in number the ratio of 1 to 10 of the members of the American Medical Association resident in such State or Territory.

Resolved, That the Secretary be and is hereby authorized to supplement such nominations within the numerical limit above specified, with appointments of members of this Association in good standing who may indicate an intention to attend the meeting in Mexico and who may apply for such credentials.

On motion, the resolutions were adopted.

DR. JOHN B. ROBERTS, Chairman of the Delegation from the Philadelphia Medical Society presented the following:

At a meeting of the Philadelphia County Medical Society, held April 15, the following preamble and resolutions were adopted:

WHEREAS, The American Medical Association completed its organization and commenced its actual existence in the city of Philadelphia during the first week of May, 1847;

Resolved, That a Committee be appointed by the Chair to publicly urge that the Association celebrate in 1897 its Fiftieth Annual Meeting with ceremonies appropriate to its long and successful career;

Resolved, That the delegates of the Philadelphia County Medical Society to the meeting of the American Medical Association at Atlanta be instructed to extend to the Association a cordial invitation to hold its semi-centennial meeting in Philadelphia, the city of its birth.

T. B. SCHNEIDEMAN, Secretary.

On motion of DR. REED, the resolutions were referred to the Committee on Nominations.

DR. I. N. LOVE, of St. Louis, alluded to the absence of a motion made by him to amend the Constitution to elect the Secretary annually, saying that it did not appear on the printed program, and asked that it be put on the list of amendments.

The President decided that this matter must be brought up at the proper time for consideration of amendments.

On motion of DR. HENRY HOLTON, of Vermont, the President was requested to appoint a committee of five to consider the recommendations in the Presidential Address.

Seconded by DR. BISHOP and carried.

DR. H. A. HARE, of Philadelphia, urged that the Committee on Nominations make its report before Friday, but the President thought it impolitic to fix the time.

DR. HARE then moved that the Committee be asked to report on Thursday. Seconded.

DR. JOHN B. HAMILTON, of Chicago, moved as a substitute that the Committee on Nominations report as soon as practicable as to the place of meeting.

Seconded and adopted.

The President after having announced that the various delegations would meet to select their members to represent them on the Committee on Nominations immediately after adjournment, the Association, on motion, then adjourned.

MAY 6—SECOND GENERAL SESSION.

PRESIDENT COLE called the Association to order at 10 A. M., after which the permanent Secretary read the list of the Nominating Committee.

The Minutes were about to be read when, on motion, further reading of them was dispensed with.

DR. E. D. FERGUSON, of Troy, N. Y., moved that the Nominating Committee meet at 9 P. M. to-day.

DR. WESTMORELAND announced that the Committee could meet at Lithia Springs this afternoon. This was accepted by Dr. Ferguson and the motion was then adopted.

On motion of Dr. Westmoreland it was agreed that the Association should adjourn at noon.

The permanent Secretary read an invitation from the Louisiana State Medical Society for the members to meet the Society at New Orleans.

On motion, the invitation was accepted.

The permanent Secretary read a number of other announcements from the Committee of Arrangements.

VICE-PRESIDENT DR. J. C. LE GRAND, of Alabama, took the Chair. He appointed as the Committee on the President's Address, Drs. Nicholas Senn, of Illinois; A. Garcelon, of Maine; Joseph Taber Johnson, of Washington, D. C.; E. S. Lewis, of New Orleans, and Dudley S. Reynolds, of Kentucky.

DR. J. COCHRAN, of Alabama—If it is in order, I desire to make a motion. I am, as you doubtless know, Mr. President, Chairman of the Committee on National Department of Public Health. This Committee has only three or four members in attendance here, and as the Committee is a small one and its work very important, I am instructed to ask that the Committee be increased so as to include one member from each State, and I make that motion.

Seconded and carried.

DR. COCHRAN was directed to appoint as many members as might be needed.

The Committee on Business presented, through Dr. E. F. Ingals, a resolution from the last meeting urging the publica-

tion of the program in future at least two weeks before the meeting.

On motion, this was adopted.

DR. I. N. LOVE—I rise, sir, for information. Last year—and I trust it is not necessary for me to make an explanation—the Nominating Committee at Baltimore in the list of officers reported a new Secretary, after careful discussion and consideration. When the report was brought before this Association, an exception was taken to that part of the report, and the point was raised that the Constitution precluded any change in the Secretaryship. I think the ruling at that time paralyzed everybody, consequently a proper consideration was not given to the question. I know it paralyzed me, and I do not easily paralyze. (Laughter). In the main, the impression was that this Association could not elect a new Secretary when it desired, which was a surprise to me. And, Mr. President, I now call for the reading of the section of the Constitution pertaining to the office of Permanent Secretary.

The Permanent Secretary read the portion of the Constitution pertaining to his office.

DR. LOVE—That covers the point. That is what I wished to elicit. I would like to know, if possible, when that part of the Constitution was adopted. Was it in the original Constitution, as adopted?

THE PRESIDENT—It was not, sir, but it was amended some years ago. I have forgotten the date.

THE SECRETARY—It was adopted in 1864 at a meeting held in New York City.

DR. LOVE—At the meeting of this Association at Baltimore, following the action of the Nominating Committee, an amendment to the Constitution was presented, which provided that this Association be permitted to elect its Secretary annually. This amendment was received and passed as having been read. There was no ruling to the contrary. It does not appear upon the printed program with the other amendments that were offered at Baltimore, and I would call at this stage for the reading of the minutes of the Baltimore meeting.

THE PRESIDENT—Are you willing to suspend this question for a little while, until Dr. Osler has delivered his address?

DR. LOVE—With the greatest of pleasure, sir. It is not my desire to bring this matter up at all.

DR. ELLIS—I move that the amendment to which Dr. Love refers be made the special order after the reading of Dr. Osler's Address.

Seconded and carried.

THE PRESIDENT—We will now listen to Dr. Osler's Address.

DR. WM. OSLER, of Baltimore then delivered the Address in Medicine, entitled, "A Study of the Fevers of the South."

DR. HOLTON—I move, sir, that the thanks of the Association be tendered to Dr. Osler for his able and interesting paper, and that it be referred to the committee on publication.

Seconded and carried.

THE PRESIDENT—The question before us for consideration now is the matter of the amendment referred to by Dr. Love previous to the delivery of Dr. Osler's Address.

DR. LOVE—Mr. President, it is antagonistic to my personal wishes to bring this matter before the Association, but I do so at the request of many of the members. In my previous remarks I made the point that an amendment to the Constitution was presented in regular form last year at Baltimore providing for the election of a Secretary annually. Said amendment does not appear upon the printed program under the head of "Amendments Offered." I desire to present a copy of it and to have the Association vote on it, if they desire to do so, or have it considered as coming up for a second reading.

ARTICLE IV. OFFICERS.

Second paragraph reads as follows: "Each officer, except the Permanent Secretary, shall hold his appointment for one year, and until another is elected to succeed him. The Permanent Secretary shall hold his appointment until removed by death, resignation, or a vote of two-thirds of the members present at a regular annual meeting."

DR. LOVE—My motion is that each officer shall hold his appointment for one year, and until another is elected to succeed him. I want this to be considered a second reading, and that it be taken up in proper form to-morrow morning at 10 A.M. Seconded.

DR. E. D. FERGUSON—I notice that our ex-President, Dr. Maclean, is on the stage, and I would like to ask him as to what his recollection was as to the disposition of this amendment last year—what his ruling upon it was at the time.

DR. DONALD MACLEAN—At the conclusion of the meeting last year I laid down with a great deal of satisfaction, gratitude and feeling of relief all the honors and responsibility of the high position to which you elected me. I now decline to

re-assume those honors and responsibilities. (Applause.) More than that, I wish to avoid everything that would bring about acrimonious debate on this occasion. I want to have continued the reign of peace the foundations of which were laid for us on the beautiful shores of the Pacific Ocean at San Francisco, and in the hope of accomplishing that object I now suggest that Dr. Love's motion be put to the meeting and let the Association decide what it will do. I do not wish to go back and assume responsibility. I do not think it is fair to ask me to put myself in that position now after having been so completely relieved of it. Therefore, I think the best solution that can be made of this question is to let the Association decide for itself whether this is the first or the second reading of that resolution.

DR. I. N. QUIMBY—As this is an important subject and there is doubt about it, I move that the whole subject be laid upon the table for another year. Seconded and carried.

There were ninety in favor of tabling Dr. Love's motion, and sixty-eight against it.

DR. H. B. ELLIS inquired why his amendment was not on the list.

The Secretary attempted to read the amendment, but Dr. John B. Roberts, of Philadelphia, objecting, it was not done.

DR. C. H. HUGHES, of St. Louis, asked for the reading of the minutes of the last day in 1895.

The Secretary attempted to do this, but owing to objection was compelled to desist.

DR. W. T. BISHOP, of Pennsylvania, moved that the reading of the minutes be continued, when a motion was made to adjourn, and the President declared the Association adjourned.

MAY 7—THIRD GENERAL SESSION.

The Association was called to order by the President at 9:30 A.M.

The Permanent Secretary read the minutes of the preceding Session, which were approved as read.

DR. ELLIS—I move that the Secretary read the minutes of the last day's session at Baltimore. Seconded.

THE PRESIDENT—The Secretary was engaged in the act of reading the minutes of this session when a motion was made to adjourn, and therefore it will be a continuation of the last session or we will have to begin *de novo*.

DR. ELLIS—The point is raised as to whether the minutes as they occur in the transactions of the American Medical Association JOURNAL are official or not.

THE PRESIDENT—If I were to express an opinion upon this subject, I should decide that they are not the official minutes. I am of the conviction that the only official minutes must be kept in a book of record, and from that book only can they be considered official, unless there is a law, of which I have no knowledge, that the reporter of the JOURNAL is an officer, or that his record is considered as official and legal. Of this matter I am not well informed.

DR. DONALD MACLEAN—It seems to me, Mr. President, that the objection to reading the minutes from the JOURNAL of the American Medical Association last year is of a rather hair-splitting nature. To expect the Secretary to produce here at any moment the written records of this Association from its inauguration to the present time, is to expect an absolute impossibility. It is the business of this Association to either confirm or reject its minutes day by day. When the minutes are adopted by the Association they are recorded in the published transactions or the JOURNAL, and if anyone wants to know at any meeting what was done with regard to a certain motion brought before this body, all he has to do is to go to his library shelves and consult the published volumes. This was done until the proceedings were published in the JOURNAL of the American Medical Association. Do you want to have produced here the stenographic report of the meeting or do you want to accept the report as published in the JOURNAL where you can read and understand it? It seems to me to make any objection on this score is unfair and is, to say the least, of a hair-splitting nature, and is hardly worthy of this Association.

THE PRESIDENT—The motion is on the reading of the minutes.

DR. DUFF, of Pittsburg—Is not the JOURNAL of the American Medical Association the official organ of this body?

THE PRESIDENT—It is unquestionably, but whether or not these reports are official is a nice question, and one that has never before been presented before to my mind. There are so many possibilities of errors creeping into the minutes that it would seem to be a very nice point when we come to consider it as an exact official record, and we would have to take the written record in the book of records. But if the Association recognizes the JOURNAL as its official organ, and that any reports appearing therein the Association is responsible for, it is another matter altogether. If you insist upon an actual

positive evidence of the original minutes, you have got to take it from the book of records.

DR. L. S. MCMURTRY, of Louisville—I do not wish to participate in any of the personal bearings of this subject. The gentleman from California (Dr. Ellis) desires to have stated to the Association the reason why an amendment that he had offered has not been presented in due form. We do not know what the amendment is. Objection was made to its reading. It seems to me the gentleman from California has a right to know something about what has become of his amendment inasmuch as it did not receive recognition upon the Secretary's minutes, and to which any member of this Association is entitled. There is no way to revise the minutes of the last day's session, unless it is done at the succeeding session. If a man is a member of an organization and presents a resolution, it makes no difference what it is, he ought to receive the customary recognition which is due him in all parliamentary bodies from the Secretary. (Applause.)

DR. W. T. BISHOP—All amendments to the Constitution must be specific, and the points clearly stated. If we admit that Dr. Ellis' motion was a part of the minutes, we would be correcting the minutes. To prevent any further confusion, I move that the question of minutes be laid upon the table, and that the JOURNAL report be regarded as the official minutes, provided they have not been corrected.

Seconded and carried.

DR. W. T. BISHOP—I now move that the minutes of all previous meetings as published in the JOURNAL be adopted as the official record. Carried.

THE SECRETARY—I rise to a question of personal privilege. I would like this Association to know how I keep my minutes. I will detain you but a short time. I write out my minutes every evening before I retire, and the editor of the JOURNAL publishes the minutes direct from my copy. If it is necessary, in the future, I will have these minutes open for inspection and recorded in a large book, but I do not think it is essential because such a book would be too cumbersome to carry around from place to place.

DR. GEORGE H. ROHÉ—I would ask whether the minutes of this session have been read?

THE PRESIDENT—Yes, sir; and approved.

DR. ROHÉ—I am glad to hear it.

DR. E. E. MONTGOMERY—I wish to make the point that the minutes to which Dr. Rohé refers have not been read. They are the minutes of the last day's session at Baltimore.

THE PRESIDENT—Dr. Montgomery is in error. Dr. Rohé asked if the minutes of yesterday's session had been read, and the Chair replied that they had been, and approved.

DR. ROHÉ—That was not what I intended to convey; I had reference to the minutes of the last day's session of the meeting at Baltimore.

THE PRESIDENT—You did not so express yourself. (Laughter.)

DR. ROHÉ—I would like to know whether this Association is willing to go on from year to year having its minutes published in the JOURNAL with no opportunity of making any corrections. The secretaries of all associations occasionally make mistakes. I think probably the members of this Association sometimes commit errors. I made one this morning myself. (Laughter.) But I acknowledged it. Most secretaries usually acknowledge when they make mistakes, but in this case no such acknowledgement has been made to my knowledge.

DR. HIBBERD, of Indiana—It seems to me, Mr. President, we are wasting a good deal of time, and I do not think there is any motion before the house.

THE PRESIDENT—No sir, not at this time, and we must proceed with the business of the Association.

The report of the Board of Trustees was then read by Dr. E. E. Montgomery of Philadelphia, as follows:

ANNUAL REPORT OF THE BOARD OF TRUSTEES FOR THE EIGHT MONTHS ENDING DEC. 31, 1895.

Gentlemen: The Trustees beg leave to present the following report for eight months ending Dec. 31, 1895.

This report covers but eight months owing to the change of the fiscal year:

	RECEIPTS.	
On hand May 1, 1895,	- - - - -	\$ 123.96
Bank collections,	- - - - -	1,047.42

Treasurer had a balance Dec. 31, 1895, of -	9,075.94
Making a total balance of - - - - -	<hr/> \$10,084.98

We feel confident you will agree with us that this is a most excellent showing, when we consider the financial condition of the country and the radical change in the policy of the JOURNAL instituted at the last meeting. A careful analysis has demonstrated that this policy has reduced the amount which would have been received from advertisements something over three thousand dollars, but we are gratified to report that the measures to secure new members which have been instituted by the trustees, and so ably carried out by the JOURNAL editor, have more than made up this deficiency. The members of the ASSOCIATION, May 26, 1894, numbered 4,032; May 1, 1896, 4,989. The regular issue of the JOURNAL at the former date was 4,876, at the present 6,548, making a gain in membership in two years of 950 and requiring an increased issue of 1,672. At present there is due the JOURNAL from subscribers \$1,400; from advertisers \$2,400.69. Since the first of the year the JOURNAL office has been moved to the Occidental building at 61 Market Street, an excellent fire-proof building, where it occupies commodious quarters upon the third floor. The previous quarters were dark, did not afford sufficient space for the work, and the property was constantly subject to danger of loss from fire. The present quarters entail an increase in cost for power of nearly sixty dollars per month. A careful study of the situation caused the trustees to feel that this change was a wise as well as a necessary one. Since the beginning of the year it has been necessary to procure an electric motor at a cost of \$350, new type at \$900, and a folder has been ordered which will cost \$1,200. The trustees have under consideration an increase in size of the JOURNAL some eight pages which will permit a review of the American medical literature, as is now done of foreign material, and other important improvements which will add to its value. The trustees feel that it will not be amiss to direct the attention of your body to the fact that all the printing and stationery for the ASSOCIATION is now furnished through the JOURNAL office. The expenses of the 1893 meeting were \$1,526.85; 1894, \$2,134.91; 1895, \$981.85; the greater part of this large reduction in expenses has been due to the changed policy and the more careful supervision of the disbursements.

The improved outlook, the increasing revenue and the lessening need for equipment renders it desirable that steps should be taken to secure permanent quarters. With this object in view, the Trustees would respectfully request that permission be granted them to establish a Building Fund, into which should be paid such portion of the surplus at the end of each fiscal year as may be deemed by the Trustees wise and expedient. Such sums to be invested until a sufficient amount has been secured to enable them to procure suitable property.

We would suggest that members of the ASSOCIATION who have been upon the list for forty years and over should be entitled to be made life members and receive the JOURNAL free of cost.

The Board has to place on record in this report, their appreciation of the valuable service of their late colleague, Dr. James E. Reeves, and their deep regret at his untimely death.

In conclusion, the Trustees would express their appreciation of the untiring efforts of the Editor and the JOURNAL employes to advance its interests.

Respectfully submitted,

A. GARCELON, President,	JOS. EASTMAN,
E. E. MONTGOMERY,	J. T. PRIESTLEY,
E. F. INGALS,	D. W. GRAHAM,
J. E. WOODBRIDGE,	I. N. LOVE,

THE PRESIDENT—You have heard the report of the Board of Trustees. What disposition will you make of it?

DR. I. N. QUIMBY—I move that it be adopted. Seconded and carried.

As the report proposed to have life members, Dr. J. T. Roberts, of Pennsylvania, asked if this could be adopted unless the Constitution was amended.

THE PRESIDENT—The Association has just voted upon the report and adopted it.

DR. ROBERTS then appealed from the decision of the Chair.

DR. D. W. GRAHAM, of Chicago, having explained the matter to the satisfaction of the Association, Dr. Roberts withdrew his appeal.

DR. DONALD MACLEAN, of Detroit—I have a brief resolution to present. It will take only a few moments to read it, but I think it requires a little explanation. I have attended the meetings of the Association for a great many years, and no man in it takes a deeper or more heartfelt interest in its welfare than I do, and it is therefore on that account that I venture to present a resolution, and in presenting it no thought of reflection or of censure is intended in any direction whatever. There never has been a meeting of this Association during which we were not greeted with the utmost cordiality and hospitality wherever we have met. If there has been any complaint it has been, that we have enjoyed too much hospitality, and arrangements have always been made with the utmost regard for the feelings of the members and the interests of the Association, and what I have just said applies to this beautiful city of Atlanta, as much as to any others where we have met. I am sure there is not a single member of the Association who will not return to his home with his heart laden with feelings of gratitude for the people and profession of this city. Having said this much, I will now present my resolution and allow it to take its course, meeting whatever fate the gentlemen of the Association may accord to it.

DR. MACLEAN's resolution is as follows:

Resolved, That it is the sense of this meeting that in future the Committee of Arrangements of the place of meeting shall be expected to avoid all entertainments and excursions which interfere with the regular work of the Association or that of the various Sections.

Seconded.

DR. MACLEAN—In following, as I have done, the peregrinations of this great and noble Association, it is only to be expected that I, like other members, would gather certain mental impressions. Certain opinions gradually form and develop and finally take definite shape. I believe that some very useful members of the Association, men who would be very desirable, have been deterred from attending the meetings from the impression that has gone forth, namely, that there is too much junketing, too much enjoyment, and too little actual scientific work. Now, I do not believe in all work and no play. That has always a bad effect. For my own part, I have always been an advocate and a practitioner of convivial enjoyment. (Applause.) No man can enjoy the pleasures of social intercourse more than myself, and I want to be the last man to put any obstacles in the way of any such enjoyment. At the same time, so far as the American Medical Association is concerned, I feel that its work is too vast, too important and too grand to be overshadowed even by convivial enjoyments, much as I like them, and therefore, Mr. President and gentlemen, I have presented this resolution in all sincerity and with none other than the purest and highest motives.

THE SECRETARY—The Executive Committee has placed in my hand the following resolutions:

Resolved, That hereafter the Secretary of the Association shall see that the Committee of Arrangements shall not provide any entertainments that will interfere with the regular work of the Association or its Sections.

Resolved, That it is desirable that the first evening of the Session be left unoccupied so that the Section dinners may then be held, and it suggests that the Association pass a resolution instructing future Committees of Arrangements to keep the first evening free for this purpose.

DR. E. F. INGALS, of Chicago—I move that the resolutions of the Executive Committee, as read, be substituted for the former resolution. Seconded.

DR. MACLEAN—I am perfectly willing to accept the resolutions of the Executive Committee. I had no idea that any such resolutions were in contemplation. I therefore withdraw my resolution.

DR. INGALS' motion was then put and carried.

DR. W. T. BISHOP—I move that these resolutions be put on the program of every annual meeting in the future.

Seconded and carried.

DR. GEORGE H. ROHÉ, of Maryland, in the absence of Dr. A. L. Gihon, read the report of the Rush Monument Committee as follows:

REPORT OF THE TREASURER OF THE RUSH MONUMENT COMMITTEE.

BALTIMORE, May 1, 1896.

The accretions to the Rush Monument Fund during the

year have been \$771, of which \$550 were derived from subscriptions and \$156 from interest on investments.

The total amount now on hand is \$3,787.64. Of this there are invested in

1 mortgage at 5 per cent.	\$2,000.00
1 mortgage at 5 per cent.	1,000.00
Deposited in City Savings Bank, Baltimore (4 per cent.).	556.00
Current deposits in bank.	194.00
Cash in hand.	37.00

Total \$3,787.64

Of the total amount subscribed during the Baltimore meeting only a small amount has been paid up. The treasurer hopes that no further reminder to those who have promised contributions will be necessary.

The names of those contributing and the amounts subscribed have been published at intervals in the JOURNAL of the American Medical Association and in other journals.

GEORGE H. ROHÉ,

Secretary and Treasurer,

On motion, the report was received and filed.

DR. HENRY D. HOLTON, of Vermont, offered to be one of forty to give \$100 toward the Rush Monument fund.

The Nominating Committee then made a partial report, namely, on the place of meeting, Philadelphia, first Tuesday in June, 1897. Unanimously adopted.

DR. HOLTON—I move you, sir, that the Trustees be authorized to establish a building fund. Such fund to be so hedged about and guarded and securely invested as shall guarantee the Association from loss. Seconded and carried.

VICE-PRESIDENT LE GRAND then took the Chair, and Dr. Nicholas Senn, of Chicago, delivered the address in surgery. Dr. Senn selected for his subject, "Some of the Limits of the Art of Surgery." (See JOURNAL, page 905.)

DR. MACLEAN—I move that the cordial thanks of the Association be tendered to Dr. Senn for the very able address which he has presented to us, and in doing so I wish as an humble student of surgery and as a practitioner, to say, that I consider this address the clarion note which will be echoed and re-echoed as far as surgery is practiced and known and studied. I believe that it is one of the very highest functions of this Association to encourage and promulgate such addresses as we have listened to to-day. If its results are not beneficial, then I know nothing of surgery or of the interests of humanity. (Applause.) Seconded by Dr. Marey and unanimously carried.

THE PRESIDENT Before we proceed further I wish to conclude the business of yesterday under the head of "Unfinished Business," and I will now call for the report of the Committee on Benevolent Organization, of which Dr. Elmer Lee, of Chicago, is Chairman.

Dr. Lee not being present the report was passed.

THE PRESIDENT We will now listen to the report of the Secretary.

SECRETARY ATKINSON then read his report as follows:

REPORT OF THE SECRETARY.

The Secretary respectfully reports that he issued about five hundred notices to the delegates present at Baltimore, notifying them of their appointment as additional members of the Rush Monument Committee.

In obedience to your order, he also sent to the President of the United States, to the Secretary of the Navy and to each member of Congress, a circular letter informing them of the resolution adopted by your body relative to the subject of rank in the medical corps of the navy. A few replies were received, but no assurance as to approval of our action. All of which is submitted. W. B. ATKINSON, Permanent Secretary.

DR. E. D. FERGUSON I move that the report of the Secretary be accepted and placed on file. Seconded and carried.

THE PRESIDENT The report of the Treasurer will now be in order.

The Treasurer, DR. HENRY P. NEWMAN, of Chicago, presented the following report:

TREASURER'S REPORT.

In offering my second annual report as treasurer of the American Medical Association, I feel that very little is required by way of prologue or of peroration.

The figures I shall present are eloquent in their own behalf and testify most solidly that the credit and financial standing of this Association is steadily and surely increasing; and as our chief source of revenue is in our membership subscription, they also evidence that we are not only one of the most prosperous medical bodies in existence, but the largest and most progressive.

Our annual reunions with their helpful fellowships and encouragement for permanent coöperation do much to promote this growth and success, but the foundation upon which our continued strength and stability most surely rest is the publication and circulation of our JOURNAL.

For the efficient manner in which he has managed this publication the thanks and the congratulations of the Association are due the able editor, Dr. John B. Hamilton, and his coadjutors, the Trustees.

At the Baltimore meeting, one year ago, I recommended in my report a change in the fiscal year, which has heretofore dated from one annual meeting to the next, to correspond with the regular calendar year.

This was unanimously approved by the Association and by order of the Trustees has been in effect during this past year.

The good results are already apparent and will be yet more evident when the slight confusion incident to the transition period is over.

There have been about eight hundred and fifty (850) new members added to the Association since May, 1895, exclusive of those joining at the Baltimore meeting. It will also be observed that our actual paid membership has more than doubled during the past year and that the annual balance in the treasury has never been so large as to-day.

H. P. NEWMAN, M.D., Treasurer, in account with the American Medical Association.

RECEIPTS.

Total		\$34,859.68

On motion of Dr. Clarke, the report was accepted and placed on file.

The following preamble and resolutions were offered by Dr. Senn, Chairman of the Committee on Vivisection:

WHEREAS, the members of the American Medical Association recognize the fact that the developments of scientific medicine have resulted largely from experiments upon the lower animals, and

WHEREAS, anesthetics are habitually administered to animals subjected to painful experiments; and

WHEREAS, restrictive legislation is in our opinion unnecessary and opposed to the continued progress of medical science; and

WHEREAS, it is an unjust reflection upon the humanity of those engaged in animal experimentation to enact laws requiring them to use anesthetics and appointing inspectors to see that they do so; and

WHEREAS, far more unnecessary pain is constantly being inflicted upon the lower animals for sport and for game than in biologic and pathologic laboratories, and

WHEREAS, no evidence has been presented by those who advocate restrictive legislation showing that abuses exist in the District of Columbia; and

WHEREAS, results of great practical importance have been obtained by experiments on the lower animals made in the Government laboratories in the District of Columbia;

Therefore, Be it Resolved, that the American Medical Association earnestly protest against the passage of Senate Bill No. 1552, entitled "A Bill for the further prevention of cruelty to animals in the District of Columbia," or any modification of this Bill, unless it shall first be shown by an impartial investigation that cruel and unnecessary experiments are being performed in the District of Columbia, and that existing laws do not provide suitable punishment for cruelty to the domestic animals.

Resolved, that copies of these Resolutions, attested by the signatures of the President of the American Medical Association and of its Committee appointed to draft these resolutions, be sent to the Chairman of the Committees in the District of Columbia, the House of Representatives and Senate of the United States.

(Signed)

DR. NICHOLAS SENN,
DR. WM. OSLER,
DR. GEO. M. GOULD,
DR. J. McFADDEN GASTON,
DR. DONALD MACLEAN.

DR. E. D. FERGUSON moved that the resolutions be adopted. Seconded.

DR. KLEINSMIDT, of Washington, moved, as an amendment, that copies of the Resolutions be sent to the Commissioners of the District of Columbia. He said that the Commissioners were the parties to either approve or disapprove of any of the Bills of the so-called Humane Society presented before Congress. Seconded.

DR. ALONZO GARCELON—Geographically the District of Columbia is but a little speck of the territory of the United States, and they have the power within their own limits to establish such police regulations in regard to the cruelty of animals that every other State has in the United States, and it seems to me that the subject is entirely unnecessary.

DR. STERNBERG, of Washington—As to the necessity for some action on part of the medical men here, I would say that a very earnest effort is now being made in the District of Columbia by residents of that District, and the Humane Society, aided by people in other parts of the country, have entered upon a crusade against those engaged in scientific research work. They have been very active, have interviewed members of Congress, and many other persons outside of the District have written letters to members of Congress, but our profession has not been heard from to any considerable extent. I beg to inform the gentleman that it is not a matter of police regulation in the District. There is an Act before Congress to regulate all such matters. The object of introducing this Bill is to obtain legislation in the District of Columbia in regard to vivisection, in order that we may subsequently urge and have similar legislation in the States. It is only the commencement. I think that it is very important that the profession should realize that and do their very best to stop any unnecessary legislation on this question on the part of the Humane Society. The resolutions asked for a thorough and impartial investigation before any legislation is enacted. We are all quite willing to have this impartial investigation made, and if there are abuses in the District of Columbia, then they can be corrected.

DR. A. H. WEST, of Texas—I wish to state Mr. Chairman, that this matter was brought before the State Medical Association of Texas, and unanimous action was taken instructing our representatives in Congress, the Senate and House, to oppose the action of the so-called Humane Society in the District of Columbia, and I believe similar action ought to be taken by this body.

The motion as amended was then put and carried.

The Secretary read the names of a number of members by invitation who were, on motion, admitted.

On motion of Dr. Willis F. Westmoreland, the program for the Jenner Centennial Memorial was made the order of business for the day.

The Secretary read the following communication from Dr. N. S. Davis, of Chicago.

CHICAGO, ILL., March 25, 1896.

W. F. Westmoreland, M.D., Chairman Committee of Arrangements of American Medical Association.

Dear Doctor:—As Chairman of the Committee appointed by the American Medical Association to devise and report a suitable program for celebrating the centennial anniversary of the

discovery of the protective virtues of cowpox vaccination by Dr. Edward Jenner, May 17, 1896, the same to occupy one entire day of the annual meeting to be held in May, 1896, I furnished a copy of the program as agreed upon by the committee to Dr. W. B. Atkinson, permanent Secretary, about the first of January last. I requested him to communicate the same to the Committee of Arrangements, which he promised to do, and he also advised me to furnish a copy to the JOURNAL of the American Medical Association. I did so, and I presume you have noticed the same in the JOURNAL of the Association for January 11, 1896, page 93. In assuming to name Thursday, May 7, as the day to be devoted to the centennial, and specifying three sessions—morning, afternoon and evening—it was not the purpose of the committee to dictate to the Committee of Arrangements, but rather to suggest. By referring to the program in the JOURNAL you will see that it embraces four important papers, each expected to be followed by more or less discussion. If the discussions were to be omitted the four papers could well be presented in two sessions. The paper or address expected by me is now complete, and its proper reading will not occupy more than forty-five minutes. I think the other three papers will certainly be ready and will be of great value.

As the By-Law of the Association makes it the duty of those intending to read papers or make reports to notify the Committee of Arrangements of the same at least one month before the expected meeting, I make this communication, and shall be much pleased to hear from you regarding the proposed program. Yours truly, N. S. DAVIS.

DR. E. E. MONTGOMERY moved that the recommendations of the Board of Trustees be referred to the Executive Committee. Seconded by Dr. Atkinson and carried.

The Secretary read the following from the Judicial Council:

ATLANTA, May 7, 1896.

In the matter of the Cleveland Medical Society.

This case having been referred back to the Association by the Ohio State Medical Society at its annual meeting May 11, 1895, your Judicial Council reports that the applications for membership of those persons belonging to said Cleveland Medical Society are still suspended, whether coming as members from said Cleveland Medical Society or any other medical society, and your Council has instructed its Secretary to notify said Cleveland Medical Society to appear before said Council to answer the charges which have been preferred against its members at the next annual meeting of the Association.

Respectfully yours,

H. D. DIDAMA, President.
X. C. SCOTT, Secretary.

The Secretary read the following from the New York County Medical Association:

Resolutions adopted at a meeting of the New York County Medical Association, held April 20, 1896.

Resolved, That this Association declares its continued attachment to the Code of Ethics of the American Medical Association, and deprecates any management of the affairs of that Association except by the various State and County associations and societies in affiliation therewith, by their regularly appointed delegates.

Resolved, That delegates appointed by this Association to the meeting to be held in Atlanta, Ga., be instructed in accordance with this action.

P. R. PORTER, M.D., Recording Secretary.

On motion of Dr. Quimby, the resolutions were received and placed on file.

DR. H. D. DIDAMA, of New York, read the address of Dr. N. S. Davis, the opening paper of the Jenner Centennial (see JOURNAL, page 915), after which the Association adjourned until 3 P.M.

AFTERNOON SESSION.

The President, Dr. Cole, in the Chair.

DR. C. F. MCGAHAN, of Minnesota, read for Dr. C. N. Hewitt, of Red Wing, Minn., a paper entitled "A Tribute to the Memory of Edward Jenner" by title.

DR. J. COCHRAN, of Alabama, followed in discussion by reading a paper.

DR. GEO. M. STERNBERG, of Washington, D. C., read a paper entitled "Scientific Researches Relating to the Specific Infectious Agent of Smallpox and the Production of Artificial Immunity in this Disease." (See JOURNAL, page 919.)

DR. H. D. DIDAMA, New York, presented by title a record by Dr. D. H. Stoner, Rhode Island, of the memorials, medals, etc., of Edward Jenner.

DR. FRANCIS E. MARTIN, of Boston, read a paper entitled "Propagation, Preservation and Use of Vaccine Virus."

DR. EUGENE FOSTER, of Augusta, Ga., read a paper entitled "Statistical Evidences of the Value of Vaccination to the Human Race."

On motion of Dr. James F. Hibberd, of Indiana, it was

Resolved, That the papers read at this Jenner Centennial celebration be referred to the Jenner Centennial Committee for revision, and selection of those deemed proper to be published in book form, and in such number as the Committee may believe there will be demand for.

Carried.

On motion of Dr. Didama, the thanks of the Association were tendered to the writers of the preceding papers.

On motion, the Association adjourned.

MAY 8—FOURTH GENERAL SESSION.

The Association was called to order at 10 A. M. by the President.

The minutes of the preceding session were read by the Secretary and approved.

The Address on State Medicine was next in order, but before delivering it Dr. Geo. H. Rohé, of Maryland, read the following telegram from Dr. Albert L. Gihon:

"Announce that the Navy Department assigns a site for Rush monument in park facing Naval Museum of Hygiene."

Dr. HOLTON moved that a vote of thanks be tendered to the Naval Department for its generous offer.

Seconded and carried.

Dr. ROHÉ then delivered the Address on State Medicine. He selected for his subject "The Purification of Water Supplies."

On motion of Dr. Ellis, a vote of thanks was extended to Dr. Rohé for his able paper.

Dr. QUIMBY—I move that the Address on State Medicine be printed in pamphlet form for distribution throughout the States. This is one of the most important matters that can come before the people at this time. I hope the Association will see fit to have at least five or six thousand reprints of this Address issued for distribution among each municipality throughout the country.

Dr. W. T. BISHOP—It certainly seems to me that this number is entirely inadequate. There is no doubt but that the people of this country are very much interested in the purification of water supplies, in the different States, and that this subject is attracting the attention of city councils.

Dr. D. W. GRAHAM, of Chicago—I move as a substitute that the editor of the JOURNAL of the American Medical Association be instructed to furnish copies of this Address at cost to all who may apply. Seconded.

Dr. QUIMBY—I accept the substitute.

The substitute was then put by the Chair and carried.

Dr. BULKLEY, of New York The Executive Committee report the following resolutions and recommend their adoption:

Resolved, That in accordance with the standing rule of the Association, the Committee of Arrangements for the next session is requested to arrange the meetings of the Association and prepare the program for the Sections so that they will not conflict. It is suggested that if the general sessions on Wednesday and Thursday be called at 11 o'clock it may remedy the difficulty.

Dr. LOVE I think the resolutions are all right, but they specifically suggest that the Committee of Arrangements prepare for the next meeting. I would suggest for all future meetings.

THE PRESIDENT I presume that was contemplated.

Resolved, That the Committee of Arrangements for next year and hereafter be directed to prepare signs for each State and Territory, also for the District of Columbia, and the Army, Navy and Marine Hospital Service, and to locate them in the hall of meeting that the delegates shall meet beneath them for the selection of members of the Nominating Committee.

Resolved, That the elections for such members of the Nominating Committee shall only be legal when held in these localities.

Resolved, That elections shall be held not sooner than 10, nor later than 30 minutes after adjournment of the first general session of the Association.

Dr. J. T. PRIESTLEY, of Iowa Supposing a delegate arrives here on the second day, how is he going to get representation on the Nominating Committee?

THE PRESIDENT He must try to get here on the first day. The resolutions were then adopted.

Dr. BULKLEY The President in his Annual Address spoke of our not having a Council such as the British Medical Association, in order that action on matters that are referred to it might be taken between the sessions. Your Executive Committee has had this point under consideration and have prepared the following:

Resolved, That there be made an Executive Council of five consisting of the three officers of the Executive Committee, and two members chosen by election. Of this Council of five, one must belong to the section on Practice of Medicine, and one to the section on Surgery and Anatomy. To this Executive Council shall be delegated all the duties of the Executive Committee during the intervals between its meetings.

The President asked whether this resolution interfered in any way with the operation of the Constitution, to which the Secretary replied: No.

Dr. X. C. SCOTT It strikes me that this is an amendment

to our By-Laws and, therefore, it must lay over until next year.

Dr. I. N. LOVE—We already have an Executive Committee to conduct the business of the Association, which is made up from the various sections, and it seems to me that this Committee, being democratic and representative in its character, is all-sufficient. It is not desirable to complicate our records by too many resolutions, and I therefore move that this resolution be laid on the table. Seconded and carried.

Dr. BULKLEY—As this resolution has been thought to be an amendment to the Constitution, I offer it to-day through the Executive Committee as an amendment.

THE PRESIDENT—To be acted upon next year?

Dr. BULKLEY—Yes, sir.

The Executive Committee called the attention of the Association to the By-Law requiring titles of papers and abstracts to be sent to the Secretaries of Sections one month previous to the date of the annual meeting and asks that it be enforced.

Dr. JAMES F. HIBBERD, of Indiana—What means have we of enforcing this By-Law?

Dr. BULKLEY—The Chairman of each Section should be directed not to receive papers later than thirty days prior to the time of meeting. For example, I finished my program and sent it to the JOURNAL almost three weeks before the meeting. It seems to me there is no good reason why the titles of papers can not be sent in two or three weeks prior to the meeting, also abstracts of the same.

Dr. HIBBERD—Are we to understand that unless papers are received thirty days preceding the meeting of the Association, that they will be excluded from presentation?

THE PRESIDENT—I do not so understand it. It is simply a call upon those who contemplate furnishing papers to have them ready thirty days before the meeting.

Dr. HIBBERD—Supposing the papers are not ready at this time, are they to be accepted?

THE PRESIDENT—That remains with the officers of the various sections.

Dr. HIBBERD—A regulation that has nothing to enforce it, is good for nothing, sir.

THE PRESIDENT—That is quite so, sir.

Dr. BULKLEY—We have not offered any resolution at all, but have simply called attention to a By-Law. It is an old By-Law and heretofore it has not been enforced. I move, therefore, that the Secretaries and Chairmen of Sections and the Local Committee of Arrangements, and all who are concerned in the preparation of the program, be directed not to receive and put the titles of papers on the program unless the authors of such papers comply with the rules, namely, thirty days before the meeting. Seconded and carried.

PERMANENT LOCATION OF JOURNAL.

Dr. GARCELON, of Maine—I have in my hand a resolution which I wish to present in order to save time. The resolution is as follows:

WHEREAS, This Association has authorized the Trustees to establish a building fund; and,

WHEREAS, The question of a permanent location for the JOURNAL has never been decided by a vote; therefore be it

Resolved, That the Trustees be and are hereby instructed to cause a vote by ballot to be taken, and on this question all members shall have the right to vote. That ballots may be received from and after June 1 until July 31, when the ballot shall close. No ballot shall be counted in favor of any particular place, unless the name of the member voting shall be signed thereto. The ballots shall be preserved by the Trustees until the next annual meeting of the Association, but the result shall be published in the JOURNAL when the count shall have been completed.

Seconded and adopted.

The report of the Committee on National Department of Public Health was then read by Dr. J. Cochran, as follows:

REPORT OF THE COMMITTEE ON DEPARTMENT OF PUBLIC HEALTH.

Our committee was appointed in 1891 with the object in view of securing the passage of a law creating a National Department of Public Health with a Secretary of Public Health at the head of it with a seat in the Cabinet of the President of the United States. The bill which was prepared for presentation to Congress was extremely crude and indefinite in its provisions, and gave this proposed high official very little important work to do. It was indeed found to be so defective that last year the effort to have it enacted into a law was abandoned.

In the meantime, the Marine-Hospital Service, which in 1890 had already been invested with some important health functions, was by the Act of 1893 converted into a National Health Department with very large and far-reaching powers and abundant means. It is not called a department of public health, but is a Department of Public Health in fact.

Since 1893 until the effort was abandoned last year, our Committee has been engaged in the hopeless and unwise enterprise of endeavoring to induce Congress to establish another depart-

ment of public health—a very weak and inconsiderable department by the side of a very powerful department. Such an effort could not succeed. Such an effort did not deserve to succeed.

It seems to us to be a fundamental proposition that we shall have but one National Department of Public Health. This being conceded, one of three courses remain open to us:

1. We may devise and advocate a plan to deprive the Marine-Hospital Service of its public health functions, and for the establishment of an entirely new department; or,
2. We may accept the Marine-Hospital Service just as it stands as a department sufficient for our present use; or,
3. We may endeavor to improve the Marine-Hospital Service and make it a more satisfactory National Health Department than it now is.

It would seem that this last method promises to be the most fruitful of beneficent results; and the question then arises as to the modifications that may be wisely made in the existing law.

In arranging any scheme of national public health supervision it would seem desirable that nothing should be done to discredit and weaken the various State Boards of Health. But that contrarywise the effort should be to strengthen the State organizations, and to foster and facilitate their further evolution. If this principle is conceded it is at once made evident that the National Department of Public Health should act in and through the State Boards of Health, in coöperation and harmony with them, and not outside of them and independent of them. If the National Department acts within the States independently of the State Boards, and assumes the work that ought to devolve upon the State Boards, then the State Boards become comparatively useless institutions and will fall into disfavor. Some of the State Boards are still weak institutions, and any rivalry between them and the National Department in State work would doom them to speedy destruction. In this direction it would seem that additional legislation is needed, and the simplest plan to reach the desired reconciliation would embrace two provisions:

1. That the National Department should act within the States by and through and in coöperation with the State Boards.
2. That the head of the National Department should call annually to meet in the city of Washington an Advisory Council to be composed of one representative from every State Board of Health. This would bring about mutual understanding and coöperation and reciprocity of action, and would virtually constitute a great central school of public hygiene.

Such a scheme as this would probably command the approval and support of the National Conference of State Boards of Health, which Conference is quite as deeply interested in movements of this character as is the American Medical Association.

As the conclusion of the whole argument, we recommend that we be authorized to draw up a new bill along the lines we have indicated, and that we be authorized to invite the coöperation of the Conference of State Boards of Health and of the American Public Health Association in our endeavor to have the proposed bill enacted into law.

All of which is respectfully submitted.

JEROME COCHRAN, M.D., Chairman Committee.

DR. HIBBERD—I move that the report of the Committee be accepted, the plan outlined adopted, the Committee continued and enlarged by the appointment of a member from each State. Seconded.

DR. I. N. LOVE—If I understand the proposition rightly, it provides for a Department of Public Health built upon the present foundation of the Marine-Hospital Service. I am therefore in favor of it. It is an elaboration, a building up in a stronger and more definite shape of the public health department and quarantine service which we already have. When we consider that every other department of life is represented in our National Conference Board, or Cabinet, and yet public health is not represented, surely the dignity of medicine and the best interests of the health of the community demand such recognition, and I think the most practical way in which to accomplish this great and good work is by building up that which we already have and crystallizing it in the shape of a more dignified body.

DR. SUMMERS, of St. Louis—I think, sir, it is time for this Association to demand of the United States of America that it should be represented in its Cabinet at Washington. We can learn a great deal from the old Christian mythology, where Gabriel was the Secretary of State, Michael the Archangel or Secretary of War, and Raphael the Secretary of Health, who flew with his wings close to the earth and shed healing in his path. Now, I say, the time has come when this Association in its power and dignity should rise and demand of the govern-

ment of the United States that it create a department of public health, as has been done in all governments of the world. This is the solution of the question. Twenty-five years ago I joined Dr. Cochran in his efforts in public health matters in Alabama, and it brought out the fact that it was possible for the State to take hold of medicine and govern it accordingly.

The report was then adopted.

The Secretary then read some resolutions referred to the General Session by the Section on Materia Medica, Pharmacy and Therapeutics, as follows:

Resolutions on the adoption of the metric system of weights and measures.

Resolved, That it is the sense of the American Medical Association that the general adoption and use of the metric system of weights and measures in the United States is very desirable, and would prove a great benefit to the people; that our trade relations with other nations would be stimulated by the unity of weights and measures.

Resolved, That this Association respectfully prays the Honorable Senate and House of Representatives in Congress assembled to pass such laws as will make the metric system of weights and measures the legal system of weights and measures in the United States.

Resolved, That the Secretary of this Association be directed to forward a copy of these resolutions to the Hon. C. W. Stone, Chairman of the Committee on Coinage, Weights and Measures, House of Representatives, Washington, D. C.

On motion the resolutions were adopted.

DR. N. SENN, of Chicago—As Chairman of the Committee to consider the recommendations contained in the President's Address, I wish to make a partial report. Our action has been anticipated by the Executive Committee in reference to one of the recommendations. We were unable to secure a full attendance of the Committee, but with the consent and support of one of the members, Dr. Garcelon, I wish to offer the following resolution:

Resolved, That the Secretary be instructed to notify the Secretary General of the International Medical Congress, that unless the English language be recognized, the American Medical Association declines to send delegates.

VICE-PRESIDENT LE GRAND put the motion to adopt the resolution, and it was unanimously carried.

The report of the Committee on Nominations was now in order and was read by Dr. H. A. West. The report is as follows:

REPORT OF COMMITTEE ON NOMINATIONS.

Your Nominating Committee presents the following names for office during the ensuing year:

President, Dr. Nicholas Senn, Illinois.

First Vice-President, Dr. Geo. M. Sternberg, Washington, D. C.

Second Vice-President, Dr. Edmond Souchon, Louisiana.

Third Vice-President, Dr. J. B. Thomas, Pennsylvania.

Fourth Vice-President, Dr. Willis F. Westmoreland, Georgia.

Treasurer, Dr. Henry P. Newman, Illinois.

Assistant Secretary, Dr. T. B. Schneideman, Pennsylvania.

Librarian, Dr. Geo. W. Webster, Illinois.

Chairman of Committee of Arrangements, Dr. H. A. Hare, Pennsylvania.

Trustee to fill vacancy, Dr. G. C. Savage, Tennessee.

Trustees, Dr. E. E. Montgomery, Pennsylvania; Dr. J. M. Mathews, Kentucky, and Dr. C. A. L. Reed, Ohio.

Judicial Council, Dr. Geo. W. Stoner, U. S. Marine Hospital Service; Dr. C. W. Foster, Maine; Dr. J. McFadden Gaston, Georgia; Dr. I. N. Quimby, New Jersey; Dr. H. Brown, Kentucky, and Dr. X. C. Scott, Ohio.

Address in Surgery, Dr. W. W. Keen, Pennsylvania.

Address in Medicine, Dr. Austin Flint, New York.

Address in State Medicine, Dr. J. Cochran, Alabama.

On motion, the report of the Nominating Committee was unanimously adopted.

The President then appointed Drs. Holton and Quimby as a Committee to escort the President-Elect to the platform.

DR. HOLTON—Your Committee appointed to wait upon the President-Elect and to conduct him to the Chair have performed this pleasant duty and take pleasure in presenting Nicholas Senn, of Illinois, as the next President of the American Medical Association. (Applause.)

PRESIDENT COLE—Gentlemen of the Association: I believe that I can speak for my dear friend upon my left. I believe I am expressing the sentiments of Dr. Senn when I say that this is the proudest moment of his life, and next to that measure of joy and pleasure that he experiences, it is the greatest pleasure of my life, next to that which I passed through on a similar occasion, to have the opportunity of introducing to you your next President. (Loud applause.)

DR. SENN was received with round after round of applause, and when quiet was restored, spoke as follows:

“Esteemed Colleague and Members of the Association:—Every American-born patriotic youth has a desire to become

some day the President of the United States, and although this opportunity only comes every four years, the progressive physician, who has the interests of his profession at heart, should make every legitimate effort to some day occupy the highest position in the gift of the greatest Medical Association in the United States. (Applause.) Few men reach the goal of their ambition. I have occupied a number of chairs, large and small, hard and soft, but I approach this, the greatest medical Chair, not only in this country but in the whole world, with a great deal of diffidence.

"This Association next year will celebrate its golden wedding. I believe we shall have the largest meeting in its history. My attendance upon the meetings for the last twenty-two years has made me painfully aware of the fact that frequently in the General Sessions the proceedings have resembled a political caucus rather than that of a scientific body. (Applause.) I hope that in this respect the next year will witness a much needed reform. This position has been made hard by the impatience of some men on the floor with selfish motives, inviting the disquietude of both the President and the rest of the audience. Let us witness few such incidents in the future. We have lost much valuable time in attacking the most sacred document in the possession of the American Medical Association—the Code of Ethics, a Code that breathes the same spirit and inculcates the same teaching as the Constitution of the United States. All of us are ever ready to die, if need be, to uphold it, to strengthen it. Without the Code of Ethics this great body would degenerate into medical anarchy, without God, without law, without order. Let us preserve the cornerstone of this great institution lest it may totter, tumble and crumble into dust. (Applause.)

"The political part of the work of this great Association should be done not upon the open floor, where we need every moment of our time to discuss the great medical questions of the day. Let us hope that in the future we may have ample committees to attend to the business part of the proceedings, and if they are found insufficient let new committees be created in order that the Sections may devote time to the objects for which this Association was founded—the advancement of American medicine and surgery. (Applause.)

"In conclusion, I desire to thank you heartily for the distinguished honor conferred upon me, and I will promise you my best efforts in performing the duties of this office." (Applause.)

The next thing in order was the appointment of delegates to the British Medical Association, the Pan-American Medical Congress, and the International Medical Congress.

Dr. D. W. GRAHAM, of Chicago—Mr. President: Did we not adopt a resolution refusing to send delegates to the International Medical Congress to be held in Moscow?

THE PRESIDENT Yes, sir. Your point is well taken. By the adoption of the report read by Dr. Senn upon the President's Address we have conditionally declined as an Association to send delegates to Russia, and therefore the President and Secretary of this Association can not issue certificates or credentials.

Dr. H. BERT ELLIS, of California, offered the following amendment:

Article 9 of the By-Laws is entitled "condition excluding representation," and reads as follows: "No State or local medical society, or other organized institution, shall be entitled to representation in this Association that has not adopted its Code of Ethics, or that has intentionally violated or disregarded any article or clause of the same."

I hereby give notice of a motion to amend so that it shall read:

"Art. IX. Condition for Further Representation. Any state or local Medical Society, or other organized institution whose Rules, Regulations and Code of Ethics agree in principle with those of this Association may be entitled to representation on the advice or agreement of the Judicial Committee."

The officers elected for the various sections, as far as they could be ascertained, are as follows:

For State Medicine, Chairman, Dr. Elmer Lee, Chicago.

Secretary, Dr. L. F. Bishop, Morristown, N. J.

Member of Executive Committee, Chas. H. Shepard, Brooklyn.

Section on Neurology and Medical Jurisprudence, Chairman, Dr. W. T. Herdman, Ann Arbor, Mich.

Secretary, Dr. Chas. H. Hughes, St. Louis, Mo.

Members of Executive Committee, Drs. J. G. Kiernan, Chicago; D. R. Brower, Chicago; and T. D. Crothers, Hartford, Conn.

Section on Dental and Oral Surgery, Chairman, Dr. R. R. Andrews, Cambridge, Mass.

Secretary, Dr. Eugene S. Talbot, Chicago.

Executive Committee, Dr. Younger, San Francisco; Dr. Geo. T. Carpenter, Chicago; Dr. R. R. Andrews, Cambridge, Mass.

Section on Obstetrics and Diseases of Women, Chairman, Dr. Milo B. Ward, Topeka, Kan.

Secretary, Dr. Geo. H. Noble, Atlanta, Ga.

Section on Laryngology and Otology, Chairman, Dr. Wm. E. Casselberry, Chicago.

Secretary, Dr. Braden Kyle, Philadelphia.

Executive Committee, Dr. E. Fletcher Ingals, Chicago; Dr. J. F. Fulton, St. Paul; and Dr. G. V. Woolen, of Indianapolis.

Section on Surgery and Anatomy, Chairman, Dr. Reginald Sayre, New York.

Secretary, Dr. Bayard Holmes, Chicago.

Section on Materia Medica and Pharmacy, Chairman, Dr. Warren B. Hill, Milwaukee.

Secretary, Dr. Frank Woodbury, Philadelphia.

There was no meeting of the Section on Physiology and Dietetics, consequently no officers were elected.

On motion of Dr. Quimby, the thanks of the Association were extended to the ladies, to the citizens, and to the local profession of Atlanta for their kindness and hospitality; also to the Southern Railway Company for its liberality.

Dr. Greenley, of Kentucky, moved that the thanks of the Association be tendered to the retiring President for the efficient and able manner in which he had discharged his duties.

Seconded and unanimously carried.

On motion of Dr. Scott, the Association then adjourned, to meet in Philadelphia, the first Tuesday in June, 1897.

SOCIETY NEWS.

Second Pan-American Medical Congress.—Dr. John B. Hamilton has been appointed Vice-President of the Auxiliary Committee at Chicago, to coöperate with the Committee of Management at Mexico. We have received at this office a number of circulars, etc., to distribute to those interested. All are in English.

We add the Secretary's appeal to the profession at large:

MEXICO CITY, January, 1896.

DR. —, *Dear Sir:*—On behalf of this Committee and in my capacity of Secretary, I have the honor to address you, begging that you will kindly contribute to the success of the Second Pan-American Medical Congress with your valuable personal assistance, beside that which you may be able to obtain in your illustrious country.

Presuming on your consent to the above, I would feel sincerely obliged if you would have the kindness to address the different medical societies, universities and schools of medicine, as well as the prominent men who are disposed to cultivate medical science, inviting them to attend this coming Congress, which will be held in the city of Mexico on the 16th, 17th, 18th and 19th of November of this year, sending also delegations whose members will forward their papers with the anticipation that is required by the accompanying regulations.

You will easily understand, and I have no doubt will impress on your countrymen, the desirability of union amongst all the nations that form the Western Hemisphere, with a view to combined labor in scientific matters, taking advantage of the facilities that we enjoy for investigation in the New World that we inhabit. With an area that covers all latitudes in two hemispheres, it is washed by the two great oceans, and consequently presents all the physical conditions that could be desired to give an immense scope to scientific investigation.

It is an undoubted fact, that the collective efforts are not the sum of the unities of which they are composed, but rather of their multiplication. If all the physicians of the American Continent and surrounding islands, were to work simultaneously in order to lay before the world at any given moment the conditions under which life is developed in each of the districts where they live; the influence of latitude, altitude and all other climatic conditions on the development of the human species, on the duration of life, on the manner in which disease presents itself, on the manner in which the organism reacts in each one of these districts, according to the conditions of the locality; the resources which each district offers to therapeutics under the varied circumstances of its climate, flora and fauna; we would be able to offer to the scientific world, and in one sole table, the medical geography, the climatology, the physiologic evolutions and all the vital data that pertain to the enormous length of the American Continent. This Congress will at the same time form a criterion of the degree of culture that has been reached by the different nations forming the great American family.

A Pan-American Medical Congress will furnish means for

studying most of the precautionary measures to be taken against epidemic and epizootic diseases; for obtaining uniformity in the nomenclature of the diseases, in order to prepare tables of mortality; for proposing uniform methods of preparing medical statistics; and in short, for giving uniformity and solidarity to all medical labors in the Western Hemisphere.

I do not doubt that your illustrious nation will contribute to this great work, sending to the Second Pan-American Medical Congress the largest personal contingent possible and a due proportion of scientific works, and I therefore hope that you will kindly notify me in answer, of the persons who propose to attend the Congress, and in due time forward me their works. I remain,

Yours very truly,

E. LICÉAGA, Secretary.

Address: Al Dr. EDUARDO LICÉAGA, Secretario de la Comisión Organizadora del 2º Congreso Médico Pan-Americano, Ciudad de Mexico, D. F. Calle de San Andrés núm. 4. República Mexicana.

The following are the

SPECIAL REGULATIONS FOR THE SECOND PAN-AMERICAN MEDICAL CONGRESS.

Article 1. In order to be properly enrolled, each member of the Congress will pay to the Treasurer thereof in the City of Mexico, the sum of five dollars in gold.

Art. 2. There will be one opening session, one closing and one intermediate session of a purely scientific character.

Art. 3. The opening session, which will be of a solemn character and presided over by the Supreme authority of the Nation, besides being attended by the members of the Congress, will also be attended by the members of scientific societies, and other distinguished persons who may be invited. The session will be opened with the report of the General Secretary.

This will be followed by a speech of welcome, pronounced by the President of the Congress.

Two members will then speak on scientific subjects, and they will be followed by a speech from the President of the Republic. It is strongly recommended, that the scientific speeches should be of short duration.

The intervals between the speeches will be filled up with musical performances.

Art. 4. At the closing session, the General Secretary will notify the place designated by the Congress for holding the third meeting.

Art. 5. The Treasurer will present his accounts to the Congress, showing the disbursement made of the funds entrusted to his care.

Art. 6. A scientific speech will be delivered and a short speech by one Representative of each one of the nations attending the Congress.

Art. 7. In the intermediate session, four speeches will be delivered on general matters, by persons who are highly distinguished in medical science, and who, having been in due time invited to do so, have accepted the commission: one of these speeches being pronounced by a Mexican physician, who shall be invited to do so by the Committee of Management.

Art. 8. No discussions will be held in the General Sessions.

Art. 9. These sessions will be held from 9 to 12 A.M. and from 3 to 5 P.M., in the places that may be designated by the Organizing Committee. They shall be presided over by the President of each section, alternating with the Vice-Presidents of each one of the nations that are represented in the respective sessions.

Art. 10. The person who may be appointed by the Committee of Organization, will be the ex-officio Secretary of each section, and he will fill his post alternately with the Secretaries of the nations who may be represented in the sections; but should the latter not be present, their places will be supplied by the President in office.

Art. 11. The President will direct the discussion in accordance with the order of the day, and will decide all questions that may arise, and that may not be provided for in these regulations.

Art. 12. The ex-officio Secretary will make out the minutes, and for that purpose, besides his own notes, will collect those of the Secretaries who may have acted in the section. He will also collect from the persons who may have spoken, the written extracts referred to in Art. 19.

Art. 13. All questions relating to the debates which are not provided for in these Regulations, will be decided in accordance with general parliamentary practice.

Art. 14. The voting will be by name or by putting the question.

Art. 15. All papers will be presented in writing.

Art. 16. Each author will forward to the Secretary of the Organizing Committee in the City of Mexico and before the

first day of August of the present year, an extract not exceeding 300 words, of the paper to be presented by him. These extracts will be printed in English, French and Spanish and will be distributed to the members of the Congress, before the session in which they are to be read.

Art. 17. No paper will be announced which is not accompanied by this extract; but the authors who comply with these conditions, will have a right to have their work published intact in the transactions of the Congress.

Art. 18. The reading of the papers in the sessions must not last more than 20 minutes; when the papers are so long that they can not be read within that time, the authors will give extracts from them, either in writing or by speech; but they will be published intact in the transactions of the Congress and in the language in which they have been written.

Art. 19. The extracts referred to in the preceding article, will be delivered at the same time as the papers, to the Secretary of the Section to which they pertain.

Art. 20. The members of the Congress who may take part in the discussions in any section, will present their speeches in writing at the termination of the sessions, to the respective Secretaries of such sections, and they will also be published in the transactions.

Art. 21. The papers which have been announced for reading in the order of the day in each section, will serve as subjects for discussion. In such discussions, no speaker will be allowed to speak more than once and for five minutes; but the author of the paper under discussion, will be allowed to reply, if he considers it necessary, in one sole speech, which will not go beyond ten minutes.

AUXILIARY COMMITTEES IN THE MEXICAN REPUBLIC.

Art. 22. These Committees will be appointed by the Committee of Organization, and will be composed of one member for each Local Medical Society, or in their absence, of one physician for every center of population. They will co-operate with the Committee of Organization in promoting the success of the Congress. Said Committees will be appointed during the first months of the present year.

EXECUTIVE COMMITTEE.

Art. 23. In order to form this Committee, the Organizing Committee will appoint seven members, including the President, Secretary, Treasurer, and the Mexican representative in the International Executive Committee, and such member will attend to everything relating to the business of the Congress, in accordance with the regulations that they may adopt for that purpose. DR. MANUEL CARMONA Y VALLE, DR. E. LICÉAGA, DR. RAFAEL LAVISTA.

Mexico, January, 1896.

Medico-Legal Society of New York.—Report of Committee of the Section on Railway Surgery on the Railway Hospital System. [From advance sheet of *Medico-Legal Journal*.]

TO THE OFFICERS AND MEMBERS OF THE SECTION ON MEDICO-LEGAL SURGERY:

Gentlemen:—Your committee to whom was referred the subject of the economy and utility of the Railway Hospital System, beg leave to submit the following summary as the result of their labor, as a report:

We are of the opinion that the experience of those railways who have established and conducted the system of hospitals, under charge of a chief surgeon, in connection with the surgical service of their lines, have been so universally successful, that we regard the following propositions as established beyond the domain of argument or question:

1. The Railway Hospital System affords by far the best means for the treatment and cure of not alone the sick among the employes, but of all sustaining injuries in the railway service, by accident or otherwise.

2. Of its economy in administration, the testimony of the managers of the railways who have adopted it, is entirely unanimous; and if established on a proper basis, where its entire cost is defrayed by the employed, who are to such an extent its beneficiaries, that in all cases they are the class most desirous of its establishment, and evince the highest appreciation of its usefulness.

3. It is practically without cost to the railway, when it is in its highest state of excellence.

4. Aside from the economy to the railway, its principal benefits may be thus classified.

a. A railway system is much stronger and in far better relations with its employes, where by the establishment of a proper hospital system, the men are sure of proper medical and surgical attention, at the nominal cost of fifty cents a month, deducted from their wages, in a service where the risk of acci-

dent and casualty is necessarily greatly increased over other avocations.

The railway employe needs protection by reason of the extra and hazardous risks he assumes, outside of and beyond his own ability to guard against.

As a matter of high policy, it is the duty of railways to thus protect its employes by all reasonable means in their power.

b. The hospital system strengthens the railway, because it gives to the sick and injured of its own employes the best medical service, restores them sooner to their duties, protects the men against careless and negligent medical treatment, and guarantees and insures them for its beneficial provisions, at such a trifling cost per capita, distributed over all its employes, as to make it in no sense burdensome or onerous to any, and it is well known that employes favor it.

c. It protects the railway against false and fraudulent claims in damage cases, to an extent that can be best appreciated by comparative results between the railway systems that have adopted it and those who have not.

d. It enables railways to offer free surgical service to its employes, or those injured by accident, which experiment has demonstrated to be of great benefit to the railway, in reducing the aggregate losses on claims for injuries.

e. In cases of accident it enables the surgeons of railways, in a large majority of cases of injury, to treat, care for and cure the injured, without cost to the railway or injured, and greatly reduce and diminish the claims for damages; and experience has shown that it is a wise preventative against fraudulent claims by unscrupulous parties.

We therefore submit the following recommendations:

1. That the establishment of railway hospitals by railways, and especially by large railway systems, have been demonstrated to be the best, most economical and beneficial for the care, cure and treatment of the sick and injured upon railways, for both the employes and the general public.

2. That experience has shown that the best hospital system, taking into consideration the wants and needs of all its beneficiaries, are those established and maintained upon the railways, under the supervision of a chief surgeon with proper medical assistants and service: the cost to be maintained by a nominal assessment upon all employes.

3. That surgical service in the hospitals be made absolutely free and without charge to all employes and all injured by accident or otherwise.

Dated April 15, 1896.

Respectfully submitted,

W. S. Outten, M.D., Chairman, St. Louis, Mo.; Clark Bell, Esq., New York; Frank H. Caldwell, M.D., Sanford, Fla.; Charles K. Cole, M.D.; Granville P. Conn, M.D., Concord, N. H.; B. F. Eads, M.D., Marshall, Texas; J. B. Murphy, M.D., Chicago; Payette H. Peck, M.D., Utica, N. Y.; J. F. Valentine, M.D., Brooklyn, N. Y.; Committee.

CORRESPONDENCE.

A Mark of Appreciation—Vote of Thanks.

CHICAGO, May 13, 1896.

To the Editor: For genuine Southern whole-souled hospitality and courteous treatment, the complimentary trip afforded by the Southern Railway Company to its invited guests and the members who participated in the excursion from Atlanta to Chattanooga, Lookout Mountain, Tate Springs, Hot Springs and Asheville, N. C., after the adjournment of the Atlanta meeting last week, excels anything in that direction that I have ever known or experienced, or indeed anything approaching it, except it be the occasion when our Association held its annual meeting at St. Paul, Minn., in June, 1882, when we were accorded similar courtesies by the Northern Pacific and Great Northern Railroads. This complimentary trip embraced about 750 miles, and the pleasant duty was assigned me to transmit the subjoined preamble and resolutions regarding the above detour trip, to the JOURNAL with the request that same be published in the current number of our JOURNAL. It is needless for me to state that they were vociferously applauded and unanimously adopted May 10, 1896, while en route, Asheville to Atlanta, and were signed by the following grateful M.D.'s on board our train. The ladies accompanying us were, however, just as much interested, and

our host was in great demand by the single members of the fair sex who accompanied us.

Ex-President Cole was the spokesman for the occasion, and right royally did he execute his duty.

WHEREAS, In the course of human events, exceptional occasions arise, which seem to demand a more formal statement of the sentiments and emotions which fill our hearts and minds than are afforded by ordinary conventional terms; and

WHEREAS, The courtesies extended by the Southern Railway Company to the undersigned members of the AMERICAN MEDICAL ASSOCIATION, especially through and by Dr. C. M. Drake, Chief Surgeon of the Company, both during the recent meeting of the Association at Atlanta and on this special excursion to Lookout Mountain, Tate Springs, Hot Springs and Asheville, demand such proper acknowledgment and statement of our sentiments, be it

Resolved, That we, the undersigned members of the AMERICAN MEDICAL ASSOCIATION and guests of the Southern Railway Company, hereby give most cordial, though imperfect, expression of our feelings in unanimously tendering the Southern Railway Company and Dr. C. M. Drake our heartfelt thanks for most generous hospitality and unremitting personal attention which we have enjoyed among scenes that, during life, will never fade from the memory of any of us who have been privileged to participate in this special excursion from the "Gateway of the South" to the "Land of the Sky."

Signed by: R. Beverly Cole, A.M., M.D., M.R.C.S. (Eng.), Ex-President AMERICAN MEDICAL ASSOCIATION, San Francisco, Cal.; A. Garcelon, M.D., Lewiston, Me.; Chas. H. Hughes, M.D., St. Louis; W. B. Atkinson, M.D., Philadelphia; Chas. W. Allen, M.D., New York; J. W. Grosvenor, M.D., Buffalo; Francis C. Martin, M.D., Boston; A. Walter Suiter, M.D., Herkimer, N. Y.; William Dougall, M.D., Joliet, Ill.; C. A. Wheaton, M.D., St. Paul, Minn.; A. D. Price, M.D., Harrodsburg, Ky.; Liston H. Montgomery, M.D., Chicago; Everett Flood, M.D., Baldwinville, Mass.; Dunbar Roy, M.D., Atlanta, Ga.; William S. Foster, M.D., Pittsburg, Pa.; G. A. Fleming, M.D., Baltimore, Md.; E. H. Squibbs, M.D., Brooklyn, N. Y.; F. E. Stewart, M.D., Detroit, Mich.; Herbert Harlan, M.D., Baltimore, Md.; Geo. W. Stoner, U.S.M.H.S., Baltimore, Md.; James D. Spencer, M.D., Watertown, N. Y.; Louis H. Jones, M.D., Atlanta, Ga.; William Warren Potter, M.D., Buffalo, N. Y.; W. F. Westmoreland, M.D., Atlanta, Ga.; R. B. Granger, M.D., New York; H. Bert Ellis, M.D., Los Angeles, Cal.; J. A. Quinn, M.D., St. Paul, Minn.; T. C. Gilchrist, M.R.C.S. (Eng.), etc., Baltimore, Md.; Frank Woodbury, M.D., Philadelphia.

Dr. Drake responded feelingly in a few well chosen words to the foregoing resolutions, which, by the way, will in the near future be followed by the presentation to him of something more material in the nature of a "loving cup" for the mantelpiece in his office, as a further testimonial of the high personal esteem and regard entertained by his friends who were on this trip. Drs. A. Walter Suiter and Frank Woodbury constitute the committee having this detail in charge.

Especial thanks are also due Assistant General Superintendent W. A. Vaughan, and the Knoxville Division Superintendent of the Southern Railway Company, who accompanied us, for courtesies extended us on the trip, which was an event of a lifetime and always to be remembered.

Very sincerely yours,

LISTON H. MONTGOMERY, M.D.

Unchastity and Credibility.

BALTIMORE, MD., May 4, 1896.

To the Editor: In the Miscellany of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for Feb. 29, 1896, there appeared an item under the head of "Unchastity and Credibility," reporting a decision of the supreme court of Missouri, that unchastity in a man does not affect his character for truth, while it does that of a woman. The decision struck me at the time as piling one injustice upon another, basing a legal discrimination against the weaker of the two parties in the act of prostitution upon the original injustice to women of a double standard of morals. I am glad to see my view sustained by the London *Personal Rights*, of April 15, 1896.

As you published the decision, will you kindly publish this

criticism of it in the interests of justice and of sound morality on the only possible basis, a single standard for both sexes.

Very truly yours,

HOWARD A. KELLY.

"UNCHASTITY AND CREDIBILITY.—'For a considerable time,' says the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 'the rule permitting a witness to be impeached by proof of general reputation for unchastity was confined, in Missouri, to females. Then the supreme court of the State held, in two cases, that the rule applied alike to both sexes, and that such reputation might be shown to discredit a male as well as a female witness. Now, in the case of State v. Sibley, the court, with three justices dissenting, overrules those two cases and reverts to its original position. Especially in a case where the defendant's character for chastity is directly involved, does the court think that such evidence is inadmissible for the purpose of impeaching his character as a witness. It is a matter of common knowledge, the court goes on to say, that the bad character of a man for chastity does not even in the remotest degree affect his character for truth, when based on that alone while it does that of a woman. It is no compliment to a woman to measure her character for truth by the same standard that you do that of man's, predicated upon character for chastity. What destroys the standing of the one, in all walks of life, has no effect on the standing for truth of the other.'

"This decision appears to us an abominably bad one. Either the court should decline to entertain the question of chastity in man or woman—and this would be by far the most equitable solution—or it should entertain it in both. To base upon the fact that woman's conduct is gauged by one moral standard and man's by another, a still further injustice, by which a woman who does that which is disregarded when done by a man is made a semi-outlaw, appears to us monstrous. In what the court speaks of as matter of common knowledge, it confounds reputation with character. The whole edifice of constructive credibility and incredibility in courts of justice ought to be swept away. It is not long since every atheist or agnostic was constructively held to be a liar; though as John Stuart Mill said, the tribunals accepted the evidence of such atheists as were willing to lie, and rejected the testimony of those who preferred openly to avow a detested creed rather than tell a falsehood."

Racial Degeneracy.

To the Editor:—Apropos of your editorial in the JOURNAL, May 9, "Anthropology as a Branch of Medical Education," I have the honor to send you an extract from a letter of Dr. Jules Goldschmidt, Paris, France, late Medical Superintendent of the Funchal Leper Asylum, Madeira. I had sent Dr. Goldschmidt, my article "Racial Degeneracy in America; Goitre and Dwarfing," reprinted from the *University Medical Magazine*, January, 1896. My conclusions were:

"Racial degeneracy may be defined as non-resistance to influences inimical to the existence of the race. The individual who can not resist the disease-producing causes which are afloat, whether they be germs, climate, or whatever their nature, is physically degenerate. If the subject has lost all power of resisting the immoral tendencies which threaten the race, he is morally degenerate. A cretin is intellectually degenerate. A dwarf is a degenerate, because he has lost the faculty of growth. Goitre is a disease of racial degeneracy; it will only be found in those races in whom development has come to a stand-still, as the mixed races of South and Central America, the Cagots, some inferior layers of the Scotch, the mixed mulatto race, and the degenerate Indians of America, etc. Leprous races are degenerate, as the Eta race of Japan, some Central and South American races; the low caste Hindoos; the poorer element of the Norwegian people. These diseases—leprosy, goitre, dwarfing, cretinism—are evidences of the dying out of a race."

Dr. Goldschmidt writes: "What you say about pre-Columbian syphilis and leprosy, and that about racial degeneracy in America is of the highest interest and greatest importance for the history of diseases and for the theory of evolution."

"You remember what Darwin says in his 'Origin of Species' about the degeneration of the rabbit in the island of Porto Santo, some 60 miles to the north of Madeira and discovered a year before the latter island. Soon after the discovery, the ordinary rabbit was introduced into Porto Santo, and the still

existing race is quite dwarfish compared to its ancestral continental prototype. . . . At last I must say a few words about tuberculosis and leprosy among the Indian tribes of North and South America. . . . Are not alcoholism, syphilis and tuberculosis the causes of the rapid disappearance of the aborigines in North America? Has leprosy any importance in this question of extinction? On the other hand are the cases of leprosy among the southern Indians not overwhelmingly more numerous than those among the northern? This question has a great importance to me especially as regards the natural disappearance of epidemics." Very truly yours,

ALBERT S. ASHMEAD, M.D.

We All Talk Shop.

To the Editor:—The thought expressed in the words which head this letter was suggested by reading in a secular newspaper an interview of which the following is an extract:

"Dr. George F. Shrady, the famous practitioner who was in attendance upon both President Garfield and President Grant, is an advisory physician to the Red Cross Hospital and a conservative man, who is widely quoted upon medical topics. He is editor of the *Medical Record* of this city, probably the most important medical journal published on the continent. At his home at 8 East Sixty-sixth Street Dr. Shrady thus expressed himself: * * * * * 'It is like a knife—good in its place. There,' said the doctor, pointing to a knife in a glass case, 'is the knife that cut President Garfield, and the knife did him good; but I would not stick it into every sick man in my care.'"

The introduction to the interview is purely reportorial, and we have little to do with it. We like to know the man whose views upon matters we note, just the same as we like to know how much experience and authority there is back of an article in a medical journal. Hence, it comes about that when it is stated at the heading of a paper that the author is a member of three or four medical societies, an *ex*-member of one or two others, a lecturer or a professor in a medical college, and particularly if he is, etc., three or four times besides, we conclude at once that the article is worth the while. But what about "the knife in the glass case?" The reporter chanced to be seated so that he could see the knife in the "glass case." Exactly. He does not say whether the chair was fastened to the floor or not? Possibly the "glass case" was not fastened to the wall, but sitting on a table? A good artist always leaves out of the picture something for the imagination to supply.

One naturally asks, but why "glass"? That's it. "He pointed to the knife," hence, in this particular instance it is fair to presume that the case, that is to say, the "glass case," was transparent; a transparent "glass case" is aseptic, so we have it. Usually, the obsolete old Code is dragged into such discussions, but this interview was had in the *Record* office, and in that sanctum professional honor is free and untrammelled by codic restrictions.

J. L. TRACY, M.D.

PUBLIC HEALTH.

What Is the Possible Minimum Death Rate?—The late Dr. Parkes fixed 17 per 1,000 as the "mortality incident to human nature," and in his time—the infancy of hygiene and sanitation—even that figure seemed Utopian. But what shall it be now fixed at in view of the reduced rate in Greater London. In 1894 the death rate had fallen from 20.5 for the decennium, 1881-90, to 17.7 per 1,000; and last year, 1895, when the mean was 19.7, there were sanitary areas in the great metropolis with the following figures: Wandsworth, 14.8; Lee, 14.5; Lewisham, 14.4; Stoke Newington, 13.4, and Hampstead, 12.

The Hygienic Importance of Amusements.—At the recent annual banquet of the French Société de Hygiène, one speaker dwelt upon the absolute necessity of providing amusements for the

masses as a hygienic measure. This was better understood in the past than now, and entertainments were provided for the people by the State. He mentioned an instance in his own experience, of a regiment whose commanding officer allowed the men to sing on the march. Health, spirits and strength flourished, and the severest exercises were play to the light-hearted men. The officer was changed and the new-comer stopped the singing, when the men drooped and the sick list grew long.

Illinois Auxiliary Sanitary Association.—The third annual meeting of the Auxiliary Sanitary Association of the Illinois State Board of Health will be held in the Capitol building at Springfield, May 22 and 23. This Association is composed of delegates and representatives of the health boards and departments of the cities and towns of the State, and the scope and objects of the organization may be inferred from the following abstract of the program: First day's session, a paper on "The Duties of Local Boards of Health as Instructors of the Public," by Arthur R. Reynolds, M.D., ex-Commissioner of Health, Chicago; "Water Analysis and the Means Provided by the State University for Making Analyses of the Water Supplies of the State," by A. W. Palmer, S. C. D., Professor of Chemistry, University of Champaign; "Tuberculosis as It Affects Animal and Man," by M. R. Trumbower, D.V.S., State Veterinarian, Sterling; "To What Extent Should Compensation Be Made for Losses Sustained by Individuals to Protect Communities from Contagious Diseases?" by Hon. M. L. Newell, Assistant Attorney General, Springfield; "Sanitary Supervision of Country Schools," by C. W. Oleson, M.D., Lombard. Second day's session: "Milk Inspection," by Adolph Gehrmann, M. D., Director and Bacteriologist, Chicago Health Department; "Duties of Local Boards of Health in the Management of Infectious and Contagious Diseases," by L. C. Taylor, M.D., Springfield; "Best Methods of Disposing of Sewage and Garbage in Small Cities," by E. P. Cook, M. D., Mendota; "Powers and Possibilities of Local Boards of Health," by A. G. Patton, M. D., Monmouth: reports of sanitary work done by cities and towns in the State by delegates and representatives.

Mortality in New York State in March. The *Bulletin* of the State Board of Health shows an unusually heavy death roll by influenza. The daily average number of deaths rose from 338 in February and 328 in January, to 358 in March, the estimated death rate being 20.00 against 18.75 and 18.50 respectively in the preceding months. Compared with March, 1895, there were 300 fewer deaths, the decrease being in deaths attributed to old age and from unclassified causes; there were 200 more deaths from consumption reported than in last March; the number from acute respiratory diseases, as well as from other local diseases was nearly the same, while the total zymotic mortality was also the same. The gripe epidemic then prevailing was estimated to have caused 1,500 deaths during the month: the mortality of the present month has been exaggerated from this cause by about 1,100 deaths, its mild prevalence for the past two months having given place to somewhat greater intensity. Measles alone among zymotic diseases shows an increase as compared with the preceding months and with a year ago: there is a more general distribution, 250 deaths occurring from it, which is a monthly mortality not often reached: a considerable number of deaths occurred in adult life. There were but 370 deaths from diphtheria, the average for March for the past ten years being 525, which represents a diminution in its mortality from 9 per 100,000 population to 6, or one third. The death rate from all causes in rural parts of the State was 17, against 21 in the rest of the State, the percentage of zymotic mortality being 6 against 11; of consumption, 9 against 12; of acute respiratory diseases, 17 against 21. One fifth of the typhoid fever mortality occurred in rural parts of the State, and less than one fifteenth of the diphtheria mortality.

Car Sanitation. Report of Standing Committee of the Section

of Railway Surgery on "Car Sanitation and the Railway Transportation of cases of Contagious and Infectious Diseases. [From advance sheets of *Medico-Legal Journal*.]

TO THE SECTION ON RAILWAY SURGERY OF THE MEDICO-LEGAL SOCIETY OF NEW YORK:

Gentlemen: The Standing Committee authorized at the November, 1895, meeting joint session—to report on the question of car sanitation, and especially on the transportation of people, sick or afflicted with infectious or contagious diseases, submit the following report:

Transportation of the sick is necessary.

It is the duty, and to the interest of *all* that railway managers consider how best to meet the exigencies of such a service, and how best to protect all who travel on railways, from the danger of infection and contagion.

In this report we will first consider tuberculosis, better known as consumption, which is a dangerous, infectious, communicable disease, the spread of which may be largely prevented by isolation, and by simple and easy means of cleanliness on the part of those afflicted, and those having the care of them. It is transmitted in the vast majority of cases from the sick to the healthy, by means of the sputum or expectoration of those afflicted with the disease.

Apartments, berths, compartments in coaches, etc., which have been occupied by a consumptive, or by a person sick with any contagious disease, should not be occupied by others, until they have been disinfected. Sick people travel under different circumstances:

1. Some take passage in an apparently healthy state, and after a few hours experience the first symptoms of infection.
2. Others suffering from an acute transmissible disease, hastily undertake a short journey, in order to reach their family physicians.
3. Others having acquired a chronic disease, travel with a therapeutic object, in search of a different climate, of a bathing station, etc.
4. The unfortunate incurables often return to die in their own homes, or among their own people.

The sleeping car is considered by all to be the point of greatest danger. Fellow passengers and employes can and should be protected. The question of car sanitation is timely, very important, and of deep interest to the traveling public of the entire world. It is also a very delicate question indeed, for the officials of our railways to consider and settle, for it affects the personal liberty of passengers.

Your committee believes, however, that when our officials fully understand the dangers arising from the present custom of transportation of people, sick with contagious diseases, that they will be found ready and willing to meet us in discussion, to receive instructions and if they can see their way clear, to adopt proper and up-to-date means of prevention.

Your committee also believes that car sanitation is an element *soon* to be advertised by railways, and in proportion to its perfection, will they receive profit and commendation.

Preventative measures are, in the judgment of your committee, the best means of averting the dangers we are asked to consider. We therefore make the following recommendations:

Prevention: 1, education of the public through the daily press; 2, legislation, State and National; 3, isolation of passengers; 4, disinfection of berths and compartments; 5, a conference between railway men and railway surgeons.

Dated April 15, 1896.

George Chaffe, M.D., Chairman; R. Sayre Harden, M.D.; Clark Bell, Esq.; J. B. Murdock, M.D.; Frank H. Caldwell, M.D.; R. S. Parkhill, M.D.; Granville P. Conn, M.D.; R. Harvey Reed, M.D.; B. P. Downs, M.D.

Health Reports. The following health reports have been received in the office of the Supervising Surgeon-General Marine-Hospital Service:

SMALLPOX—UNITED STATES.

- Kentucky: Paducah, April 21 to 31, 4 cases, 2 deaths.
Louisiana: New Orleans, April 25 to May 2, 31 cases, 12 deaths; April 1 to 30, 248 cases, 92 deaths.
Michigan: Bay City, April 25 to May 2; Ionia, April 25 to May 2; smallpox reported.
New York: New York, May 2 to 9, 1 case, 1 death.
Tennessee: Memphis, April 1 to 30, 6 cases; Shelby County (not including Memphis) 41 cases, 3 deaths; Covington, April 1 to 30, 2 cases; Cedar Point, April 1 to 30, 1 case.
Washington: Seattle, April 25 to May 2, 1 case.

SMALLPOX—FOREIGN.

- Alexandria, April 1 to 8, 1 death.
Birmingham, April 18 to 25, 2 cases.

Bombay, April 2 to 14, 75 deaths.
 Bristol, April 18 to 25, 1 case, 1 death.
 Cairo, April 1 to 8, 4 deaths.
 Calcutta, March 21 to April 4, 13 deaths.
 Cardiff, April 18 to 25, 1 case.
 Cienfuegos, April 19 to 26, 8 deaths.
 Corunna, April 4 to 25, 10 deaths.
 Gibraltar, April 12 to 19, 1 case.
 Madrid, April 14 to 21, 10 deaths.
 Montevideo, March 22 to April 4, 6 cases.
 Moscow, April 4 to 11, 1 case.
 Naples, April 20 to 27, 8 cases, 3 deaths.
 Odessa, April 11 to 18, 20 cases, 1 death.
 Prague, April 11 to 18, 10 cases.
 St. Petersburg, April 11 to 18, 35 cases, 4 deaths.
 Swansea, April 18 to 25, 3 cases.
 Warsaw, April 11 to 18, 1 death.
 Rio de Janeiro, March 28 to April 11, 7 deaths.

CHOLERA.

Alexandria, April 1 to 8, 19 deaths.
 Bombay, April 2 to 14, 14 deaths.
 Calcutta, March 21 to April 4, 535 deaths.

YELLOW FEVER.

Havana, April 28 to May 5, 12 cases, 5 deaths.
 Rio de Janeiro, March 28 to April 11, 305 deaths.

NECROLOGY.

AN OBJECT-LESSON IN LONGEVITY.—Readers of the JOURNAL are not unfamiliar with the name and fame of the subject of

DR. WILLIAM REYNOLD SALMON, M.R.C.S.

[By courtesy of the Chicago Times-Herald.]

the accompanying illustration. William Reynold Salmon, M. R. C. S., of Penllyn Court, Cowbridge, Glamorganshire, South Wales, completed his 106th year on March 16, and died on the 11th of the present month—at the time of his death the

oldest known individual of indisputably authenticated age, the oldest physician, the oldest member of the Royal College of Surgeons, England, and the oldest Freemason in the world. His age does not rest upon tradition or repute. He was the son of a successful and esteemed practicing physician of Market Wickham, Suffolk, Eng., and there is in the possession of his two surviving relatives, who cared for his household for many years, his mother's diary, in which is inscribed in the handwriting of a lady of the eighteenth century, under the date, Tuesday, March 16, 1790, a prayer of thankfulness to God that she had passed her 'tryall,' and that a son was born, who she hoped 'would prosper, be a support to his parents, and make virtue his chief pursuit.' The Royal College of Surgeons verified this record many years ago, and it was subsequently again authenticated by the authorities of the Freemasons, who thereupon enshrined his portrait in their gallery as the oldest living Freemason. The Salmon family moved to Cowbridge in 1796, so that the doctor had lived exactly a century in the lovely and poetic Vale of Glamorgan, in the very heart of which Penllyn Court is situate. Here on his 106th birthday—a man of over middle height, with still long flowing hair, druidical beard and mustache, and bushy eyebrows—Dr. Salmon was visited by one who writes:

"Seen a few days ago, the Patriarch of Penllyn Court was hale and hearty. He eats well and sleeps well and was feeling better than he had felt for the last five years. On that day he rose at noon, dined at 6, and retired at 9. Drank two glasses of port with his dinner, but did not smoke. He abandoned his favorite weed at the age of 90, and had to discontinue his drives over his beautiful estate in his 100th year. One day is much the same as another, for he gives his two relatives little trouble in attending upon his wants. Dr. Salmon has not discovered the elixir of life, for the shadows of life's evening are stealing slowly over him. He can not move about, his hearing is dulled, and the light is almost shut out from the 'windows of his soul.' Let us think of this remarkable man waiting for death uncomplainingly in his old-fashioned mansion, surrounded by the beautiful foliage and the broad expanse of green fields that he loved so much to roam when a younger man, in that sylvan Sleepy Hollow in the Vale of Glamorgan."

Eight weeks later he, who in youth had been "the youngest surgeon in the army," died, the oldest physician in the world.

MARIANO SEMMOLA, M.D., Professor at Naples and Senator of the Kingdom of Italy. Born in 1831, he was one of the most brilliant scientific men of Italy, and almost as well known outside by his numerous writings on his specialties, experimental pathology and therapeutics, and also his contributions to medical conventions. He delivered one of the general addresses at the International Medical Congress in Washington, 1887.

CONSTANTIN PAUL AND J. LEFORT, M.D.—The Académie de Médecine at Paris has just lost these two honored members. The former from a street lad had become one of the most popular physicians of Paris.

JOSEPH SPATH, M.D., at Vienna, one of the famous group that made Vienna's reputation a generation ago. He had been living in seclusion for some years, on account of blindness, since he was compelled to abandon his practice and the chair of Gynecology in 1886.

J. W. SCOTT, M.D. (Starling Medical College, Columbus, Ohio, 1855) died of heart disease, at Cleveland, Ohio, May 5, aged 74 years. He was born in Culpepper County, Va., and moved to Columbus in 1856. He was the first president of the Cleveland Medical Society and was appointed to the Chair of Materia Medica when the Charity Hospital Medical College was organized in 1863, and went with it when it joined the Western Reserve University. He was a member of the State Medical Association, the AMERICAN MEDICAL ASSOCIATION and other medical and medico-legal societies.

O. W. STONE, M.D. (Medical School of Maine, Brunswick, Me., 1878), died of consumption, at Boulder, Mont., April 30.

—George A. Fiegenbaum (St. Joseph's Medical College, St. Joseph, Mo., 1880) of stricture of the esophagus, at St. Joseph, Mo., April 30, aged 41 years.—George D. Stevenson, M.D., formerly of the City Hospital Staff of Newark, N. J., May 2.—Wm. A. Strother, M.D. (Med. Depart. University of New York City, 1861), died of pneumonia, at Albany, Ga., May 2, aged 56.—Orrin D. Todd, M.D. (Pennsylvania Med. College, 1865), at Eminence, Ky., May 4.—Claude Wilson, M.D. (College of Physicians and Surgeons of New York, 1876), died of pneumonia, at Waterville, N. Y., April 22, aged 48 years.—W. C. Gibson, M.D. (Jefferson Med. College, 1880), one of Macon's most popular physicians, died at Vineville, Ga., April 25, aged 39 years.—P. I. Spenser, M.D. (Med. Depart. University of Wooster, Cleveland, 1871), died of heart disease, at

Cleveland, Ohio, April 27, aged 59 years.—Conrad Secrest, M.D. (Rush Med. College, 1870), died at Watseka, Ill., April 28, aged 67 years.

MISCELLANY.

Odessa, Russia, is to have a medical college and large connecting hospital to cost 1,400,000 rubles, which has just been appropriated by the government for the purpose.

The Boston Medical Library.—At a meeting of the Boston Medical Library Association, it was voted to change the name of the Corporation from Boston Medical Library Association to Boston Medical Library.

Population of Greater New York.—It is estimated by Dr. Roger S. Tracy, of the New York City Board of Health, that the number of persons living within the limits of "greater New York" is 3,195,059.

The Official Languages at the International Medical Congress at Moscow in 1897.—Yielding to the universal protest, the Committee of Management have announced that English and German will also be accepted as official languages, with French and Russian.

A Colony for invalid children has been organized in southern Russia which boards and cares for a child for the entire summer for 70 rubles. The age is limited to 14 to 16 years, and the troubles are mostly scrofulous, rheumatic, neurasthenic, etc. It is the work of a Russian society for the preservation of the health of the poor.

Second Pan-American Medical Congress.—The Committee on Organization of the second Pan-American Medical Congress at Mexico City, Mexico, have notified, through their Secretary, Dr. Eduardo Liceaga, Dr. H. L. E. Johnson that he had been appointed the Vice-President of the Congress for the District of Columbia. Local organization will commence at once.

Experiments on the Power of Absorption of the Bladder.—Alapy finds that there is no absorption from the bladder in rabbits, in the case of non-volatile substances, but that the volatile, gas-producing substances are absorbed very rapidly, such as anilin, pyridin, collidin, picolin, nicotin, etc.—*Centralblatt f. Chirurgie*, April 18.

Unique Effect of Inductive Currents on Living Bacteria. Motile bacilli are the only organized beings that possess the property of being turned around by an inductive current. They always turn immediately in the direction of the current if they are alive, but it has no effect upon them if dead, showing that the electricity has some direct relation to the vitality of their protoplasm. (Lortet) *Semaine Médicale*, April 29.

"Sapient Beldames" or Gratuitous Prescribers. Dr. Henry Ling Taylor, speaking in *Pediatrics* of a certain form of shoe largely advertised and used for the "support" of weak ankles, pays his compliments to its producers in an emphatic way. This kind of appliance, he says, "may be a great commercial success, but it is a clog and a hindrance and should be consigned to the armamentarium of those *sapient beldames of both sexes*, who never know what is the matter, but invariably know what to prescribe."

Methylene Blue Stands Side by Side with Quinin in the treatment of malarial troubles, is the conclusion announced by Röttger Kieh after observing seven cases of intermittent fever treated with six to eight powders of 10 centigrams each, during the day, for eight to twenty-three days. No unfavorable results followed except where it was kept up too long, when it produced a general depressing effect, arrested at once by suspending it. *Semaine Médicale*, April 22.

A Lemon Worn as a Pessary. Bérard describes the case of a woman of 68, who had used for twenty-two years a lemon as a

pessary to control prolapsus, accompanied by rectocele and cystocele. She changed the lemon every month herself, until the time when she had to apply to Bérard for assistance. There were no alterations in the vagina, nor excessive discharges, and the lemon, which had been in place more than a month and a half, showed no signs of decay. The *Journal de Méd. de Paris* (April 19), remarks that there may possibly be a valuable suggestion in this case, as the antiseptic properties of lemon rind are well known. Pellissier even recommends in obstinate cases of gonorrhea, urethral injections of citric acid, 8 grams to 1 liter water.—*Memorabilien*, April 11.

Medical College Association.—The Association of American Medical Colleges held its annual meeting in Atlanta May 4. The business transacted was formal and routine. The requirements for membership remain the same, namely, preliminary examinations in, 1, English, 2, mathematics, 3, physics, and 4, Latin, and four years of study in a medical college, at least six months each year. Dr. James M. Bodine, of Louisville, Ky., was elected president, and Dr. Bayard Holmes, of Chicago, reelected secretary. The work of the committee on syllabus was accepted and the committee continued.

Serum "Treatment" for a Mind Diseased.—Mairet and Vires of Montpellier, announce the curious fact that in two cases of acute mania treated with the serum from a cured maniacal case, one was much improved, but relapsed when the injections were discontinued. The other was cured. The calm secured was permanent; reason returned and the patient was dismissed as cured.—*Semaine Médicale*, April 22.

Discussion of Fatality Following the Use of Antitoxin.—While Behring's serum is being lauded at the medical congresses around the world, the press in its birthplace is denouncing it in no measured terms on account of the fact stated in the following death notice that recently appeared, over the signature of one of the best-known physicians there: "Died suddenly yesterday, in the midst of perfect health, our child, 20 months old, immediately after one preventive injection of Behring's serum." Eulenberg, in a scathing article in the *Deutsch. Med. Wochsch.* of April 16, deprecates this abuse, and states that the fact of the death resulting so instantaneously shows that it was not due to the serum, but probably to embolism or to the introduction of some air, or to some carelessness in the operation, injecting, perhaps, into a vein, as he remarks that there are very few poisons virulent enough to produce such instantaneous results if injected in the proper place in the proper way.

Practical Notes.

Gavage or Forced Alimentation.—Rousseau St. Phillipe described at the meeting of the *Acad. de Méd.*, April 14, his process of feeding prematurely born or feeble infants by administering milk in a pointed spoon through the nostril, the infant lying flat on his lap, with the head slightly raised.

Painting with Guaiacol in Pneumonia.—Maldaresco reports the results of a hundred cases treated in this way as very favorable. He painted the posterior thoracic wall, and repeated it whenever the temperature rose above a hundred, for two to four days. After this the temperature remained normal, when he administered quinin and alcoholic drinks. With elderly people and children he used almond oil and guaiacol at 40 per cent.—*Semaine Médicale*, April 11.

Nuclein in the Treatment of Puerperal Septic Disorders.—Nuclein has been used in Europe by Sée in pneumonia, and Professor Schauta of Vienna, and Hofbauer have been using it recently in seven cases of puerperal infection. Two cases were beyond all relief when it was used, but the other five cases all showed improvement and rapid recovery after its administration. Nuclein is supposed to stimulate the production of leucocytes in the organism, and the patients each experienced a painful sensibility in the bones, similar to that observed in leukemia,

which Hofbauer ascribes to the increase in the leucocytogenous power of the bone marrow under the influence of the nuclein. —*Semaine Médicale*, April 29.

Galvano-Therapeutics to Reduce Hypertrophied Prostate.—*La Semaine Médicale*, of April 22, states that there is no record of the galvanic current applied although faradization has been tried, and describes at length a case treated by Minervini, of Naples, with great success, where there was complete retention of urine. After six treatments the urine showed itself, and with thirty, covering a period of forty-two days, normal functions were restored.

Icteric Fever and Hematuria Produced by Quinin and Beans.—Tomasselli has called attention to the fever, hematuria and pronounced jaundice caused in some persons by quinin, and Pucci describes in the *Gazz. degli Osp. e delle Clin.* of April 2, seven cases, all of which were preceded by similar symptoms produced by eating green beans. He found this intolerance of beans in all the chronic cases of intolerance of quinin. But three cases of severe jaundice, fever and hematuria caused by eating green beans and much aggravated by the administration of quinin, recovered entirely in couple of weeks, and quinin administered later produced no unusual effects.

Carbid of Calcium in Epithelioma of the Uterus and Vagina.—Guinard arrests and relieves the pains, hemorrhages and fetid discharges by introducing into the vagina a piece of carbid of calcium, about the size of a nut, and tamponing the opening with iodoform gauze. It develops acetylene gas in contact with moisture, and there is a burning sensation at first, but this soon passes away, in four hours at most. Four days later he washes out the vagina freely with a 1,000 solution of sublimate, carefully removing every incrustation. He recommends this treatment highly, although he has only had three months experience with it. Its power to arrest the hemorrhage immediately, renders it peculiarly valuable. —*Progrès Médical*, April 8.

Inter-Cricothyroid Laryngotomy.—Richelot advocates this operation as far more simple and beneficial in adults than tracheotomy. There is no injury to an important organ to be feared, and a simple bistoury and Krishaber canule are all that are required. Place the nail of the left index finger on a level with the lower edge of the thyroid cartilage, on the median line, and turn the head slightly to enlarge the space between the cartilages, then make an opening one centimeter in length. The cricothyroid membrane is opened with the point of the bistoury and the tube inserted. The whole operation takes less than a minute. A canule of 9 to 10 millimeters is a great help to respiration. He has seen them worn for months, and cause very little inconvenience, even in cases of tuberculosis and cancer, where the cartilages are liable to be degenerated and easily torn. —*Bulletin de l'Académie de Médecine*, April 21.

Fatal Diabetic Coma Supervening upon Influenza. Dr. E. S. Cadnan reports in the *British Medical Journal* a case of the above nature as follows:

"On Feb. 29, 1896, I saw Mrs. H., aged 42. She was almost completely comatose. I had attended her for a normal confinement in December, 1893. She continued in good health till the beginning of 1895, when she had influenza, but only an ordinary attack, and complained of no symptoms which would lead one to suppose she was suffering from diabetes mellitus. Until about eight weeks before my visit she enjoyed fairly good health. She then suffered from a second attack of influenza, which never made her keep her bed, and was accompanied by the usual symptoms; she never complained of great thirst or polyuria, soon recovered, and I did not see her again till February 29, when I obtained the following facts from the husband: During the previous six weeks she had suffered from great thirst, drinking at least one gallon of fluid in the day; her appetite was not altered in the same way, in fact she took about her usual quantity of food; she had lost flesh extremely fast, and complained of great lassitude. She passed large quantities of urine. The character of the breathing reminded me forcibly of opium poisoning, but when compared closely the dyspnea was too labored and not peaceful enough. The

lips were red and there were no signs of cyanosis; the pupils acted very sluggishly to light, but were of normal size. When asked to put out the tongue she did so, but could not answer any question: the tongue was exceedingly dry, hard and brown; and felt like a piece of dry leather. She was extremely emaciated, and the skin was harsh and dry. The temperature was subnormal and the pulse small, frequent and feeble. She lay still, except that sometimes the head was moved from side to side and occasionally she muttered incoherently. The urine obtained by the use of the catheter had the characteristics of diabetic urine; the specific gravity was 1025; it contained a small amount of albumin and gave well-marked sugar reactions and also the acetone reaction with perchlorid of iron. The stupor, which commenced between midnight and 1 A. M. of February 29, gradually deepened into coma, which was fully established on March 1, when she was evidently sinking fast. Death took place at 10:30 P. M., about forty-six hours after the commencement of the stupor."

Hospital Notes.

The twenty-fourth annual report of Roosevelt Hospital of New York shows that the number of patients admitted during the year was 3,101, of which 1,429 were discharged cured, 1,198 improved, and 343 died. There were 2,875 free patients, and the cases treated in the accident room reached 5,485.

The new Santa Fé hospital at Topeka, Kas., said to be the finest railroad hospital in the world, was formally accepted April 27, by General Manager Frey as chairman of the board of trustees, and the building is now the property of the Hospital Association. The cost was \$100,000, exclusive of the site, and the fund was raised by monthly assessments of the employés of the road. Dr. George W. Hogeboom is chief surgeon.

Detroit.

AT THE REGULAR MEETING of the Detroit Medical and Library Association, May 4, Dr. A. N. Collins read a paper upon "Intestinal Obstruction." In his paper he calls attention to the seriousness of a condition which is liable to be met with by the general practitioner at any hour, and he points out how necessary then it is for every practitioner to have a thorough knowledge of the causes, conditions, symptoms and treatment of the trouble. Intestinal obstruction is simply a condition, and in considering it the main difficulty lies in getting at the cause. In his paper the Doctor considered only the acute condition. The classification which he gave was based upon the cause, and was that of Dr. Sands, with an addition of his own, external hernia and food accumulations. The reason he gives for making this addition is that in his experience it has been one of the most common causes and productive of the characteristic symptoms. Intussusception is the commonest cause in children and hernia in adults. He speaks of paralysis of a section of the intestine as a frequent cause. In considering the treatment, he speaks of how serious a matter it is for the attending physician, after having made a diagnosis, to decide if an operation is necessary, for many cases will recover without surgical interference. He cites several cases which occurred in his own practice, in which after operation was advised and before the operation could be performed, the symptoms cleared up and the patient recovered. On the other hand, he cites several cases which came under his notice, in which no treatment but surgical would or could be of any avail. He gave as his opinion that many more lives would be saved if, after operation had been advised, the operation could be performed immediately, without the necessary delay of taking the patient to the hospital, and the ill effect that moving would have upon his condition.

THE WAYNE COUNTY MEDICAL SOCIETY at its regular meeting, May 7, listened to an interesting paper by Dr. Willard Chaney entitled "Deviations of the Septum."

HEALTH OFFICE report for week ending May 9, 1896: Deaths under 5 years, 31, total 78; births, male 46, female 40, total 86. Contagious diseases: Diphtheria last report 9, new cases 5, recovered 1, died 1, now sick 12; scarlet fever, last report 17, new cases 14, recovered 3, died none, now sick 28; measles, last report none, new cases 1, recovered none, died none, now sick 1.

Washington.

WEEKLY REPORT OF THE HEALTH DEPARTMENT.—The Health Officer makes the following report for the week ended May 2: There was a decrease in the mortality of the District over 31 per cent. as compared with the previous week. The annual death rate fell accordingly from 21.0 to 15.10, while during the corresponding period of last year the rate was 23.26, the normal

point. According to the reports received at the Health Department, there were 80 deaths, as against 116 by the last report. The improvement in the general health resulted mainly from a cessation of brain and heart affections and a fall in deaths from consumption from 22 to 12. There was one death from typhoid fever, 1 from diphtheria, 2 from measles and 1 from whooping cough. Other than these the zymotic contagious diseases were in abeyance. The mortality among the colored population exceeded that of the white by 16 per cent. New cases of diphtheria reported were 2, while 4 houses were released from quarantine, thus leaving four still isolated. Of scarlet fever 4 new cases were reported, quarantine was raised from 4 houses and 5 were left placarded.

DENTAL ASSOCIATION MEETING.—The third union meeting of the Washington City Dental Society and the Maryland Dental Association was held in the Columbian Medical School Hall on the 8th inst. Many important dental subjects were discussed. The attendance was large.

CHARITABLE APPROPRIATIONS BY CONGRESS. The following items are noted in the appropriation bill just favorably reported by the Senate: Central Dispensary and Emergency Hospital, \$15,000; Children's Hospital, \$10,000; Homeopathic Hospital, \$8,500; Hospital for Foundlings, \$6,000; St. Ann's Infant Asylum, \$5,400; Eastern Dispensary, \$1,000; Home for Incurables, \$2,000; \$8,000 for enforcement of act to prevent spread of scarlet fever and diphtheria.

COLUMBIAN UNIVERSITY GRADUATION. The graduating exercises of the dental department of the University were held on the 5th inst. Thirteen received the degree of D.D.S. The medical department exercises were held on the 7th inst. with twenty graduates.

MEDICAL PRACTICE ACT. The Medical Practice act which passed the House some time ago was passed by the Senate on the 9th inst., with two additional amendments, and finally passed on the 11th. The act does not take effect until July 1, 1896. One of these amendments provides that the proposed board of medical supervisors, which is to grant licenses, shall not recognize physicians coming from States which do not grant equal rights and privileges to the licentiates of the District board, and the other makes the law applicable to the medical students who have matriculated in any medical college in this District prior to Jan. 1, 1896.

Another measure of interest to the medical profession which was agreed to related to the testimony of physicians in the District courts and reads as follows:

That in the courts of the District of Columbia no physician or surgeon shall be permitted, without the consent of the person afflicted, or of his legal representative, to disclose any information, confidential in its nature, which he shall have acquired in attending a patient in a professional capacity, and which was necessary to enable him to act in that capacity, whether such information shall have been obtained from the patient or from his family or from the person or persons in charge of him: Provided, That this act shall not apply to evidence in criminal cases, where the accused is charged with causing the death of, or inflicting injuries upon, a human being, and the disclosure shall be required in the interests of public justice.

The report accompanying the bill shows that its enactment was vigorously opposed by the six justices of the supreme court of the District of Columbia, on the ground that if it became a law it would be a serious obstruction to justice in contests over life insurance, personal injury from negligent or willful acts, wills, and other litigation, in which mental capacity was involved. The judges took the ground that the doctors did not occupy the same privileged position as the lawyers in confidential communications. They stated broadly that the bill was not susceptible of any amendment that would make it unobjectionable, and that such legislation would be detrimental in every way. In answer to this, the Medical Society, through President Busey, submitted a lengthy argument, and upon this reply the favorable report of the Senate District Committee was based, and the bill finally passed May 11.

MEDICAL SOCIETY. At the meeting of the Society held on the 6th inst., Dr. C. H. Alden, U.S.A., read a paper entitled "Treatment of Alcoholism from report of Army Medical Officers." Dr. Chappell reported the history of a fatal case of extrophy of the bladder.

THE PUBLIC SERVICES.

Competitive Examination.—There will be held at Washington, D. C., on June 15, 1896, a competitive examination of candidates for appointment to the position of Assistant Surgeon in the U. S. Marine-Hospital Service. Candidates are required to be not less than 24 years of age, and no appointment is made of any candidate over 30 years of age. They must be graduates of a reputable medical college, and furnish testimonials as to character.

Successful candidates, having made the required grade, are appointed

in order of merit as vacancies arise during the succeeding year. There is at present one vacancy.

A successful candidate, when recommended for appointment, is commissioned by the President of the United States as an assistant surgeon. After four years of service and a second examination he is entitled to promotion to the grade of passed assistant surgeon, and to the rank of surgeon, according to priority, on the occurrence of vacancies in that grade.

The salary of an assistant surgeon is \$1,600 per annum, together with furnished quarters, light and fuel. That of a passed assistant surgeon \$1,800 per annum, and that of surgeon \$2,500 per annum. In addition to the above salaries, after five years' service, an additional compensation of ten per cent. of the annual salary for each five years of service is allowed medical officers above the rank of assistant surgeons, the maximum rate, however, not to exceed forty per cent.

When an officer is on duty at a station where there are no quarters furnished by the Government, commutation of quarters is allowed at the rate of \$30 per month for an assistant surgeon, \$40 for a passed assistant surgeon, and \$50 for a surgeon. The successful candidates, after receiving appointments, are usually ordered to one of the larger stations for training in their duties.

Full information may be obtained by addressing the Surgeon-General of the Marine-Hospital Service, Washington, D. C.

Army Changes. Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from May 2 to May 8, 1896.

Major Daniel G. Caldwell, Surgeon, having been found incapacitated for active service by reason of disability incident to the Service, is, by direction of the President, retired from active service this date, May 2, 1896.

Capt. Charles E. Woodruff, Asst. Surgeon, now at Ft. Sheridan, Ill., is detailed for temporary duty as attending surgeon in Chicago, retaining his station at Ft. Sheridan.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending May 9, 1896.

P. A. Surgeon A. M. D. McCormick, detached from the Naval Academy, and ordered to the "Bancroft."

Medical Inspector Daniel McMurtrie, ordered for examination for promotion May 8.

Surgeon W. A. McClurg, detached from the "Concord," home and three months' leave.

P. A. Surgeon P. H. Bryant, detached from the "Petrel," home and three months' leave.

Medical Inspector J. M. Flint, Surgeon J. C. Byrnes and P. A. Surgeon C. F. Stokes, are appointed a board to examine applicants for admission to the Naval Academy.

Change of Address.

Bellamy, B. C., from Stockton to Livermore, Alameda County, Cal.
 Buskirk, J. D., from Bradley to Grandville, Mich.
 Coffman, G. L., from St. Louis, Mo., to Thayer, Kas.
 Davidson, F. S., from 1004 Morse Ave. to 528 Morse Ave., Chicago, Ill.
 Epstein, A., from 776 Jackson Blvd. to 619 Monroe St., Chicago, Ill.
 Eichberg, L. R., from 4056 Indiana Ave. to 3312 Calumet Ave., Chicago.
 Formanek, F., from 1171 Millard Ave. to 251 Ogden Ave., Chicago.
 Griffin, M. A., from 708 Monroe St. to 1291 S. Port Ave., Chicago, Ill.
 Hemenway, S., from Bonanza to Klamath Falls, Ore.
 Kirkbride, W. F., from Philadelphia, Pa., to Spring Lake Beach, Pa., P. O. Box 215.
 Lawrence, G. H., from 47 N. Sheldon St. to 891 Jackson Blvd., Chicago.
 Montgomery, Liston H., from 70 State St. to Room 18 Central Music Hall, Chicago, Ill.
 McLeod, J. H., from St. Louis, Mo., to care Wabash Hospital, Springfield, Ill.
 Prentiss, D. W., from Hamilton Parish, Bermuda, to 1218 Ninth St., Washington, D. C.
 Parks, W. R., from Chicago, to 1458 Maple Ave., Evanston, Ill.
 Rotgeb, H. D., from Wellington to East Lynn, Ill.
 Silva, C. C. P., from 281 Warren Ave. to 132 Ashland Blvd., Chicago.
 Shoup, Jessie, from 312 Indiana Ave. 117 Maryland Ave. N. E., Washington, D. C.
 Stett, O. J., from 190 55th St. to 25 E. 44th St., Chicago.
 Westcott, G. D., from 1280 Adams St. to 1625 Fulton St., Chicago.
 Wood, W. S., from St. Louis to Elmo, Mo.
 Watkins, S. E., from 1213 N. St. N. W. to 1119 O St. N. W., Washington.
 Weir, L. J., from Chicago to West York, Ill.
 Woltze, Jno., from 467 W. Chicago Ave. to 445 North Ave., Chicago.

No. 21.

ADDRESSES.

THE STUDY OF THE FEVERS OF THE SOUTH.

The Address on General Medicine, Delivered at the Forty-seventh
Annual Meeting of the American Medical Association,
at Atlanta, Ga., May 5-8, 1896.

BY WILLIAM OSLER, M.D.

PROFESSOR OF MEDICINE JOHNS HOPKINS UNIVERSITY,
BALTIMORE.

Humanity has but three great enemies: Fever, famine and war; of these by far the greatest, by far the most terrible, is fever. Gad, the seer of David, estimated aright the relative intensity of these afflictions when he made three days' pestilence the equivalent of three months' flight before the enemy, and of three (seven) years of famine. As far back as history will carry us, in ancient Greece, in ancient Rome, throughout the middle ages, down to our own day, the noisome pestilence, in whatsoever form it assumed, has been dreaded justly as the greatest of evils.

It is worthy of comment that three of the greatest benefits conferred on mankind—beside which it would be hard to name three of equal importance—have been in connection with the fevers: The introduction of cinchona, the discovery of vaccination and the announcement of the principle of asepsis. Too great a boon for a single era, these priceless gifts have been distributed over three centuries. They represent great practical applications of our art in three departments: Cinchona bark in therapeutics, vaccination in preventive medicine and asepticism in surgery. Each of the diseases thus attacked in its stronghold may be taken as a type of a great group of the fevers, the miasmatic-contagious, the eruptive and the septic.

Although in connection with the fevers the century can claim but one discovery of the first magnitude: yet the sum of progress in all directions has been vast. If asked to name the most conspicuous, those which have helped us most to fulfill our highest functions in the relief of suffering and the prevention of disease, I would say, the differentiation of the continued fevers, the enouncing of the gospel of medical cleanliness, the recognition of the microbic origin of many diseases, and the introduction of rational methods of treatment.

I have chosen to address you *on the study of the fevers of the South*, since I felt that here no subject lies so near to the general practitioner, no question requires to be so often discussed with freedom and clearness, and no place in the civilized world offers better opportunities for the solution of some of the many complex problems as yet unsolved. I shall not refer to yellow fever, that dreaded foe which each generation has had to face, happily in epidemics of ever lessening extent and duration. I can not pass it, however, without reverently paying a tribute to our colleagues who have fallen in the fight. The unselfish devotion to

the good of our fellow creatures, which animates our best work, has given to physicians in every age a spirit which in times of great peril has enabled them to meet the gravest emergencies. No epidemics have blazoned forth in such relief the heroism of our fellows as those of typhus in Europe and of yellow fever in America.

The differentiation of special forms of the continued fevers, and particularly that of typhoid, is one of the most interesting chapters in medicine. "There is but one fever. Of course I do not admit of its artificial division into genera and species." So wrote the great Benjamin Rush, whose theory of the unity of fever with twelve primary states and innumerable combinations was a reaction from the complicated nosology of Cullen. Of the three generations of physicians of this century, the first never emerged from the chaos in which Cullen, Rush, *et al.*, left it; from the horizon of the second the thick clouds began to clear away; while we of the third live in the dawn, at any rate, of order.

The correlation of the fevers, the passage of one into the other, their transmutability and mutual substitution were articles of faith of our grandparents. Let me read you a paragraph from that delightful biography of John Armstrong by Francis Boott (1835), a work which should be read by Southern physicians who wish to learn how much good work was done by their predecessors in the early years of the century. "In taking, therefore, a general review of the diseases of North America, which owe their origin to malaria, we observe yellow fever almost annually epidemic at Vera Cruz, lat. 19° 11'; and that it gradually disappears in frequency as we approach the latitude of Boston. 42° 20'; that in the parallel of Philadelphia it often ends in typhus; that north of this line, typhus becomes the more frequent form of fever, till we lose all trace of yellow fever in Vermont, as a distinct disease, the symptoms of both, however, being sometimes blended in the same case; that both of them are attended, from the south to the north, with diarrhea, dysentery, cholera infantum in the summer, and in the winter and spring with a pleurisy or peripneumony, which in the south is more decidedly marked, like the autumnal fever, with bilious symptoms; sometimes, as Rush observed in 1803, with a tendency to a tertian type; and in the north, having, like its fevers, a more typhoid character, sometimes approaching to the most malignant forms of congestive fever."

The passage of remittent into yellow fever, the relations of the malarial to the continued fevers, the connection of pneumonia with malaria, were questions discussed at extraordinary length. Careless of the type, they attributed a mobility and plasticity to the individual fevers which we can not understand with our ideas of fixidness, and of a true breeding of the germs. The literature was in indirect bulk to the accuracy and positiveness of their knowledge. Vol-

umes to them were as articles to us. Take, for example, the enormous literature on the question which stirred so deeply the second generation of physicians in the South; the relations of malaria with pneumonia. What a wordy war it was! And how Manson and W. T. Howard belabored each other! René La Roche could only undertake the consideration of the question within the limits of a modest brochure of above five hundred pages! To us the crop may not seem to have been worth harvesting, but the soil left barren could scarcely have grown the grain by which we to-day live, and any student may read in the contributions between 1820 and 1860 an ever growing appreciation of the value of accurate clinical and pathologic observations.

In the study of fever the profession in the United States received during the third and fourth decades an extraordinary impulse from France. Previous to this English medicine had controlled the situation, but for years following their deaths, Hunter and Cullen had no worthy successors. No more arid period exists in British medicine than that which followed immediately upon the exit of these giants.

Laennec, with his marvelous discoveries in clinical medicine, was a ferment of extraordinary potency. To him, and later to Louis, the young men of this country turned for inspiration. While Laennec's work is eternal his career was brief, and it was particularly from his immediate successors in Paris, and above all from Louis, that American students received at this time their intellectual impulse. The introduction by him of the numerical method, and the rigid and accurate study which he made of typhoid fever, stimulated everywhere a more careful anatomic and clinical consideration of fevers of all sorts.

But Louis' work, great as it was in France, has had a far wider sphere. No European teacher has ever had so devoted or so distinguished a band of American students, upon whom was poured out a full measure of his spirit. James Jackson, Jr., Oliver Wendell Holmes, Henry I. Bowditch, Geo. B. Shattuck, John A. Swett, Alonzo Clark, Elisha Bartlett, Caspar W. Pennock, W. W. Gerhard, Thomas Stewardson, Alfred Stillé and William Power. What a splendid band! All of them "caught his clear accents, learned his great language and made him their model." Industry with accuracy, zeal with judgment, honesty with candor, characterized these men, who may be said truly to have changed the whole method of clinical work in this country. There was a certain *Je ne sais quoi* quality about this group which pertains to no other in the history of American medicine. Perhaps it is best expressed by the term *Brahmin*, as Oliver Wendell Holmes uses it, men to whom *noblesse oblige* was not mere verbiage. Alas! that but one of the group remains, full of years and honor, and as his recent address shows, faithful to the methods of his master, ever faithful to the highest interest of his profession. The work of these men has been worthy of them. I am never tired of telling the story of the differentiation of typhus and typhoid fever, in which they with a number of young men in different countries took part. I can not bore you with it here. The chief credit is due to W. W. Gerhard, of Philadelphia, but so well did Louis' pupils leaven the mass that Gerhard's paper, and the studies of James Jackson, Jr., Enoch Hale, Geo. B. Shattuck and Alfred Stillé made the distinctions well and widely known early in the forties. So solidly had the work been

done, that in the first edition of Bartlett's work on fevers, 1842, we have the separate accounts just as they are given to-day; and three editions of the work had appeared before Jenner brought conviction to the profession in Great Britain.

Yellow fever is now a rare visitant in the South; smallpox occurs only in local outbreaks; typhus fever has not been seen by the present generation of physicians; cholera has not been epidemic since 1866. Gradually, but surely, the great epidemic diseases have been driven from the land. Even malaria has diminished extraordinarily in its extent and in its intensity, particularly above the latitude of Norfolk. One only of the continued fevers persists, almost, we may say, in its original vigor. Typhoid fever is to-day in the United States *the fever*, just as it was when the old New England physicians recognized its recurrence year after year with the fall of the leaves. Of no disease is the history better known; the measures for its prevention are everywhere recognized; the incidence of its occurrence is an unfailing index of the sanitary intelligence of a community. With good drainage, pure water and pure milk, typhoid fever goes the way of typhus and cholera. The greatest sanitary triumphs of the century have been in reducing to a minimum the mortality from this disease in the great centers of population in Europe. The mortuary returns of Washington and of Baltimore, and of many smaller cities demonstrate that we are culpably negligent in allowing this most easily preventable disease to continue its ravages. I estimate that in the latter city there were during the year 1895 not less than 2,500 cases.

The greater prevalence of the disease last year in many cities in the Union was associated with temporary conditions upon which I need not dwell. Certain cities in which sanitary measures have been carried out recently, as Chicago, have showed even a diminution in mortality. But to one feature in connection with the disease I should like to call the special attention of the members, viz., its increasing prevalence in smaller towns and in the country. Accurate data are impossible to obtain, as compulsory notification of cases is not carried out, but in many States, particularly, so far as I know, in Pennsylvania, Maryland and Virginia, the cities have suffered less than the suburban and rural districts. Are we not responsible, in part at least, for this condition of affairs? Have we given enough attention to local health matters? Have we preached, in season and out of season, the gospel of cleanliness? And, most important of all, have we always realized the paramount importance of neutralizing the poison in each case? There is an urgent need in counties and smaller towns of a more systematic enforcement of the laws of health. We do not appreciate here, as in England, the value of well organized health boards with properly paid officials, and with modern equipments. Rural sanitation needs reorganizing, and the increase of typhoid fever is the best comment on the unsatisfactory nature of the present state of affairs.

It is a very gratifying sign to notice the attention which has been given of late to the subject of typhoid fever in the South. Some years ago a good many physicians resented the imputation that the disease to any extent prevailed in the Gulf States. I have been in the habit for several years past of reading the reports of the discussions on this subject at the New Orleans Parish Medical Society. They have

been interesting, as showing a progressive development of knowledge, such as comes to all of us with fuller study of any problem. Enteric fever presents no constant picture; on the contrary, scarcely any disease has a more varied symptomatology. The fever may be said to be invariable, though afebrile cases are not unknown; but in the features of onset, in the length of its course, in the presence or absence of symptoms regarded as cardinal, such as rose spots, diarrhea and splenic enlargement, typhoid fever is so uncertain that the diagnosis is often dubious. We have now, as I shall mention, an unerring means of differentiating malaria, with which here the disease is so often confounded. We are still without a ready means of recognizing under all conditions, typhoid fever, a method available even for the hospital physician. Elsner's plan, if it turns out successful, will be useful where there is a well equipped laboratory, but the general practitioner must trust to his past experience, to his common sense and to his special senses to recognize the disease. Mistakes can not be avoided, and there are cases, as in every disease, in which a diagnosis can not be reached.

Advances in the treatment of fevers, and especially of typhoid, have not kept pace with the rapid progress in our knowledge of the etiology. In the present condition of bacteriology we may hopefully expect great things in the near future, but meanwhile we jog along without any fixed aim, too often carried away by winds of doctrines and wild theories. Still it is something to have escaped from the restless activities of our grandfathers. They were not all, however, of the same stamp. If I had typhoid fever and had a theosophic option as to a family physician I would choose Nathan Smith, nor would I care whether it was while he labored in the flesh in the little town of Cornish, N. H., in 1798, or after he had become the distinguished Professor of Medicine in Yale.

I know of no more graphic contrast than can be drawn between the comfort of fever patients at the beginning and at the close of the century. In illustration let me give you an account which I picked up last summer in the Medical Library at Boston, from a brochure by Dr. Gamage on the fever of 1817-18 in that city. He was describing a typical case of typhoid fever with several relapses, which occurred in a woman, whom he saw about the first of February. In the first attack, between February 3 and 28, she had seventeen bleedings, varying from fifteen to twenty ounces; in all, 167 ounces of blood were taken. She had active purgation and calomel galore. There were blisters to the neck, blisters behind the ears, blisters on the abdomen. Throughout March, April and May the patient had three, if not four, relapses, in each of which there were renewed bleedings, though the amount of blood was rarely more than four to six ounces. The purging and blistering were kept up, but there was added on several occasions cold ablutions, and thrice she had tepid baths. In the very full record which he gives of the case it is evident that scarcely forty-eight hours passed without some active medication.

Think of the misery, the tediousness, the discomfort of a typhoid case with three relapses; think of the bleedings, the blisterings, the purgings, from which at least our fever patients of to-day are free! Contrast the quiet, the care, the gentle nursing, the scrupulous cleanliness, the abundance of cold water

to drink and the fresh air which typhoid patients of to-day receive. A practitioner of the Nathan Smith type, a man who has the confidence of his patients, will carry through a majority of his typhoid fever patients without a single dose of medicine, not a purge, not a vomit, not even a fever mixture. He is a patient, anxious spectator of a process he can not arrest, a watchful guardian who will know when to act with promptitude and decision and when to refrain. Would that worthy successors of this good old man (whose article on the typhous fever of New England shows him to have been a true disciple of Sydenham) were more numerous. Some of us insist, and I am one of them, that in hospital practice a cold bath every three hours, when the fever arises above a certain point, saves from eight to ten in each century of cases; while there are others—*quo! homines, tot sententie*—who put their trust in purges, or who undertake to disinfect the twenty feet of bowel with drugs whose chief virtue is their harmlessness.

Old Dr. Gamage, whose case I read to you, with that delightful complacency which has not yet disappeared from our ranks, congratulated himself and his patient that success had crowned his efforts. He concludes his paper with the words, "thus no less than four distinct accessions of the disease occurred. That they were the effects of the spreading and augmentation of the inflammatory action is proved by the fact that the symptoms in each instance were reduced within the bounds of present safety by bleeding, and the patient allowed another chance for existence." Pity, no doubt, is the chief feeling in our minds as we read such a report; but this is our day, not his. At some future time there will come a day, perhaps, when our complacency will seem as strange, when other auditors, in another place, may express the same pity for us that we feel for our predecessors. Even Rush seems to have had a presentiment that perhaps he did not know it all, since he closes his article on the phenomena of fever with the lines:

"We think our fathers fools, so wise we grow.
Our wiser sons I hope will think us so."

We don't!

I must claim the privilege of a faddist to abuse roundly other faddists who do not swim in my puddle. As a strong advocate of hydrotherapy, I take especial pleasure in denouncing as heretics of the worst possible stamp, the advocates of the so-called, antiseptic and abortive methods of treatment of typhoid fever. I would place the man who does not for this purpose also give a purge, in a limbo just a little less hot, as he probably does a little less harm. It galls my kibe, too, to think that the heresy is spreading, and scarcely a week passes in which I do not receive a temperature chart of some case of typhoid fever which has terminated spontaneously, on the twelfth or fourteenth day, as a triumphant demonstration of the value of drugs which, from my point of view, might as well have been given *per cutem* in the tub. At present I am so wholly abandoned to cold water practices that I confess to be anything but an impartial critic. Still, intestinal antisepsis is not a matter for typhoid fever patients only, and now that the glamour with which Boucharde invested the subject is fading, we are getting to hard common sense views on the question. Two facts—the two grains of wheat in the two bushels of chaff—which you can winnow from the whole complex literature to date about antiseptic medication, are: First, that in such a disease as chol-

era, in which the germs thrive and grow directly in the bowel, is a failure; and second, the impossibility of destroying experimentally germs in the bowel by any antiseptic administered *per os* in harmless doses.

The advocates in this country for the abortive and antiseptic plan of treatment must bring forward a much stronger body of evidence than has been presented, and in a much more rational way, before they can hope to carry conviction to the sceptic. Indeed, more than this, they must not regard themselves as exempt from the common rules which are recognized everywhere in modern medicine as essential. If they have a jewel, why, for pity's sake, ruin it in the setting? I have no hesitation in characterizing the papers which have appeared in the ASSOCIATION JOURNAL on the question as a heterogeneous jumble, entirely unworthy of the best traditions of the profession; unworthy of a subject connected in this country with the names of Bartlett, Gerhard, James Jackson and Flint. I am not one to cry: Can any good come out of Nazareth? Nor do I hold that all wisdom is in the professorial corps. Jenner was not a professor, nor was Sims; nor am I so blinded as to suppose that we come to the end of our wisdom in the treatment of any disease; but I do insist that the advocates of any special line of treatment should, at any rate, advance their claims with some regard to the intelligence of their readers, with some regard to the ordinary rules which regulate sane men in the presentation of a subject. To assert an abortive treatment of typhoid in a case in which on the thirteenth day of the illness, and on the seventh of the treatment, a patient died of intussusception, "cured of his typhoid fever on the seventh day of treatment," so it is stated, when the autopsy showed "the characteristic and extensive ulceration of Peyer's patches and tumefied glands," is to talk a language unintelligible to an educated medical man, and is nothing short of midsummer madness. Then follows the extraordinary remark, "The history and pathologic specimens prove conclusively that one case of typhoid fever was aborted. *Ab uno disce omnes.*" Such a conclusion would insult the intelligence of a first year medical student. To speak of a case of typhoid fever as aborted, which shows on the thirteenth day ulceration of the ileum and tumefied mesenteric glands, dams, in my opinion, the whole plan as a therapeutic fake of the very first water. *Ab uno disce omnes!* Another piece of evidence is mentioned in a case in which the disease was so far aborted as to enable the patient to sit up and eat beef-steak on the tenth day. He remained well for fifteen days, and then, *mirabile dictu*, this aborted fever had the audacity to relapse! The advocates of the abortive and antiseptic plan must, 1, learn what it is to abort a disease; 2, familiarize themselves fully with the clinical history of the milder types of typhoid fever; and, 3, present their reports of cases in a manner worthy of the subject, giving details which shall enable anyone to deduce his own lesson. I honor, Mr. President, enthusiasm, and respect honest conviction, but when principles are at stake which involve the good name of my colleagues and of my profession, and still further when in my judgment the lives of patients are placed in hazard I hold it better to speak out plainly than to maintain a supine, though more easy, silence.

I have spoken of the discovery of cinchona as one of the three greatest benefits conferred upon mankind in relation to the fevers, an event fraught with more

memorable consequences than any perhaps in the history of medicine. It has made waste places habitable, the wilderness to blossom like the rose, and has been one of the great factors in the expansion of European civilization. After two centuries and a half cinchona remains the only specific drug which we have in the fevers, to the action of which the *pharmacoepia* offers no parallel.

The clinical phenomena of malaria were better known to the old Greek and Roman physicians than those of other fevers. The writings of Sydenham and Morton in the seventeenth century, and Lancisi and others in the eighteenth century, served to give unusual fulness and breadth to the knowledge of paludism. I have read an extract from Armstrong's biography which gives an idea of the confusion which existed in the early part of the century, and which illustrates the uncertainty in the minds of the best workers just how far the malarial influence extended. In our own day the confusion has not disappeared, and until recently it was impossible to say accurately what was and what was not true malaria. So simple in some of its manifestations, so complex in others, it was quite difficult, on the one hand, to recognize all its protean features; and on the other hand, in affected districts, the tendency was irresistible to attribute to paludism any malady of a periodic type, or with specially anomalous symptoms. Confidently predicted by many, its presence formulated in as early as the year 1849, by J. K. Mitchell, the parasite of the disease remained unknown until 1880, the date of Laveran's discovery. The demonstration of the invariable presence of the *hematozoon* described by him is now as complete as it is possible to have anything in the range of medicine. It may be stated confidently that in no part of the world in which malaria prevails has any worker with a proper knowledge of the technique and suitable instruments failed to discover the parasites. The importance of the study from the standpoint of diagnosis can not be over-estimated. It gives the practitioner at all times and in all places an unfailing means of differentiating the malarial from other fevers. No one can now approach the study of the subject without familiarizing himself fully with what has been done on this question, and particularly upon the varieties of the malarial parasite, and the differences of type in the different forms of the disease. Though the work which has already been accomplished, particularly by the Italian observers, is far reaching and satisfactory, to some of the problems which remain I may here briefly refer.

We need more particularly a study of the condition of the blood in the irregular forms of malaria, such as prevail more particularly in the region of the Gulf States. Here at the outset the workers who have an opportunity of studying these forms are frequently nonplused by the scanty number of parasites in the blood. These are the very instances in which, as has been shown, the organisms are chiefly in the viscera, and the severity of the symptoms is almost directly proportionate to their number in the vessels of the spleen, bone marrow, intestines, brain and the other organs. There are cases in which the life of the patient depends directly upon the diagnosis, and upon the promptness with which the patient is placed under the influence of quinin, either by the hypodermic or intravenous injection.

The subject of malarial hematuria, which is year

by year discussed in our journals, has to be worked at anew from this modern standpoint. What are its exact relations to malaria? What is the form of the organism present in these cases? What are the pathologic changes in the kidneys and other organs? These are questions which await solution at the hands of expert men who have been trained in the modern methods of blood work. A practical point of the greatest importance bearing upon this question is the much debated relation of quinin to the hematuria. If the bleeding is caused directly by the presence in large numbers of the parasites in the kidneys, it runs directly counter to our knowledge of the action of quinin to suppose that it could in any way aggravate the hemorrhage. But the matter is one upon which in its present condition hopelessly irreconcilable views are held by general practitioners. The actual nature of the so-called malarial hematuria must, I think, first be settled.

Another subject to which particular attention should be given is the occurrence of malarial infection in other diseases. The coexistence of malaria with dysentery is well known. Malaria may develop in the course of pneumonia, and there may be a concurrent infection with malaria and with typhoid fever. Though undoubtedly this may happen, yet it must be extremely rare, as in the now very large number of cases of both diseases which we have had at the Johns Hopkins Hospital, all with careful blood examinations, there has not been a single instance in which typhoid fever and malaria were concurrent, although very many of our cases of typhoid fever come from malarious regions. Now that there has been such a strong reaction in the profession against the idea of the typho-malarial fever broached by Woodward, I would like in justice to that distinguished man to call attention to the fact that in his well-known paper at the International Medical Congress in 1876, he distinctly denied that what he termed typho-malarial fever was a specific fever—a new disease, but he expressly used the term “concurrent elements,” and there can be no question, I think now, that malaria and typhoid fever may coexist, but also there is no question that the malarial element may be quickly and efficiently disposed of by the administration of quinin. I repeat that there is no subject to which the young physicians of the South can devote themselves with more profit than to the study of malaria from the modern standpoint. The necessary technical knowledge can be obtained by two or three months’ study in a well equipped clinical laboratory. Without such training it is useless to go into the question. The whole literature of the subject is now readily accessible. The student will find in the volumes of the late Joseph Jones reference to much of the older literature, and a host of valuable clinical data collected by that most industrious observer, whose death recently we have had to lament. The New Sydenham Society has issued several monographs,¹ and in this country the monograph by my assistants, Dr. Thayer and Dr. Hewetson,² gives full details.

Apart from typhoid fever and from the irregular forms of fever due to malaria, is there a third type of fever in the South independent of both? This is perhaps the most important question awaiting solution in regard to the fevers of this locality. The idea

of the existence of such a separate fever is not new. Armstrong held that in the West Indies there was a common fever arising from heat acting on unseasoned constitutions. The disease has received many names: *Florida fever* in Florida, the *country fever* in the Carolinas, and by French writers it is spoken of as *fièvre inflammatoire*. Guitéras, who brought to the study of the question a peculiarly intimate acquaintance with yellow fever in the tropics, and also a thorough knowledge of the common types of typhoid fever in the North, has called it *continued thermic fever*. He says: “These cases deserve to be classified as an entirely distinct group, and to my mind must be recognized as a distinct disease. I have examined some of these cases of prolonged fever of southern countries, postmortem, and have failed to find the lesions of typhoid fever; I therefore think that my conclusion in regard to these cases is a correct one. The farther south we go, the more frequently we shall find that there is a certain fever which is peculiar to the region.” The literature of the subject is quite extensive, but we are not prepared as yet for a final decision of the question. The subject is of the very first importance, and demands renewed attention at the hands of those who have the opportunities. It is not in the far South only that this form of fever has been described, as shown by the papers of Robinson and Baumgarten on the simple continued fever of St. Louis.³

One or two significant facts have been brought out within the past few years. The careful observations made in Galveston by West and by Dock show that the two main types of fever in that city are malaria and typhoid fever. I have already referred to the discussions which have taken place during a series of years in the New Orleans Parish Medical Society, which showed a strong evidence of a belief in that city in the existence of a third type of fever. In a paper by Dr. Matas of that city, published a year and a half ago,⁴ he retracts his previous opinion, after nine years’ additional experience, and holds that the long-continued fever of Louisiana that resists quinin is really typhoid fever. Some of his conclusions in this matter may be quoted with advantage.

“The course of the long-continued fevers of Louisiana is not in the least altered or notably influenced by the cinchona alkaloids; *ergo*, it is not a malarial fever from the therapeutic standpoint.

“That this fever occurs at all seasons of the year, though it is more prevalent during the summer months; *ergo*, it is not a ‘thermic’ fever pure and simple.

“That cases of the fever occur in groups (and probably in districts), several members of a household being attacked simultaneously or in rapid succession; *ergo*, infection from a common source.

“That while the true classical and grave typhoid type of fever is exceptional and comparatively rare, it nevertheless exists in our midst in persons who are born in this city and who have never lived elsewhere; *ergo*, typical typhoid fever exists as an epidemic in New Orleans.

“In infected houses, where several cases are under treatment, it is not very rare to observe a fever of a most *typical* and grave typhoid type running through its course by the side of a benign *atypical* fever in which there are no adynamic symptoms, no diarrhea,

³ Transactions of the Association of American Physicians, Vols. III and VIII.

⁴ Medical News, Dec. 15, 1894.

no hemorrhages; nothing, in fact, but a simple and uncomplicated thermic movement."

The question has suffered in the way in which it has been approached, and I may be allowed to suggest that those who have opportunities, both in the cities and in the country districts, should adopt the following methods:

In the first place, full clinical histories should be furnished of the cases. A man who wishes to contribute to the subject should not be too busy, not only to make a careful, critical study of the symptoms, but to jot them down in some order, so that at least they may be intelligible to others.

The second point is the necessity of obtaining autopsies in fatal cases. We all appreciate how difficult this is in private practice, but in determining the nature of obscure atypical cases of fever it is absolutely essential. There is not a hospital in the country in which the determination of the nature of obscure cases of fever is not settled by the autopsy alone.

And thirdly, it is essential that observers who undertake to study this question with thoroughness should approach it with a full acquaintance with the varieties of the malarial parasites, and with an accurate knowledge of bacteriologic technique.

Utopian as it may appear, we may look forward with hope to the day when the great enemies of our race shall be no more, when fever, war and pestilence shall cease to harass mankind.

When we glance at the progress of the century, have we not say that at least the beacon fires of hope have been lighted? The enormous advance in material prosperity, and the closer linking of the nations which has followed the annihilation of space by steam and electricity, has made widespread devastating famine almost impossible, and has, at any rate, set a limit to the range of its power for ill.

For one only of the three great curses the close of the century brings no gleam of hope. It will be in another democracy, in another century, perhaps far distant, that the race will realize the earnest longing of the son of Amos, that "nation shall not lift up sword against nation, neither shall they learn war any more." The gradual growth of a deep sense of the brotherhood of man, such an abiding sense as pervades our own profession in its relation to the suffering, which recognizes the one blood of all the nations, may perhaps do it. In some development of socialism, something that will widen patriotism beyond the bounds of nationalism, may rest the desire of the race in this matter; but the evil is rooted and grounded in the abyss of human passion, and war with all its horrors is likely long to burden the earth.

To us as a profession belongs the chief glory of the century. Enormous as has been the advancement in material prosperity, and wide-spread as has been the diffusion of benefits from the development of the physical sciences, they can not compare with the progress which has been made in the relief of suffering, and in the prevention of disease. Our work here ranks among the most memorable achievements in the history of the race. Fever in its varied forms is still with us, and, as I said at the start, the century has seen in connection with it but one discovery of the first magnitude, but it is of almost equal importance to know that the way has been opened, and that the united efforts of many workers in many lands are day by day disarming this great enemy of the race.

THE PURIFICATION OF PUBLIC WATER SUPPLIES.

The Address on State Medicine, delivered at the Forty-Seventh Annual Meeting of the American Medical Association at Atlanta, Ga., May 5-8, 1896.

BY GEORGE H. ROHE, M.D.

BALTIMORE, MD.

The most vitally important sanitary problem confronting American municipalities at the present day is, unquestionably, the supply of pure water for drinking and other domestic purposes. The wide-spread prevalence of typhoid fever may be practically looked upon as a measure of the pollution of the drinking water. Depending as this disease does almost entirely upon an infected water supply, the importance of having the latter of a pure quality is self-evident. In 1894, twenty-five of the principal cities of the United States had an average typhoid mortality of 39.6 per hundred thousand of population. Those cities which had the largest mortality from this disease were supplied by a highly suspicious quality of drinking water.

It will be hardly necessary at the present day to insist upon the etiologic relation of infected water to typhoid fever. The numerous epidemics in this country and abroad, which have been studied with so much care by eminent sanitarians, have demonstrated this relation. While cases doubtless occur in which the disease can not be traced to the water supply, these constitute the vanishing minority, the overwhelming majority being unquestionably due to infected water.

In epidemics of cholera a similar relation exists between the outbreaks and extension of the disease to an infected water supply. Aside, however, from the production of these specific diseases, pure water, or water free from all sorts of uncleanness, is demanded by the "sanitary conscience" of the public.

These premises being conceded, the great importance of securing a supply of drinking water free from contamination, becomes apparent.

In sparsely settled districts, or where a supply of unpolluted water can be brought from a distance to a large community, it will probably be better to secure such a pure supply rather than purify a source of supply which has been polluted; but in the majority of instances, particularly in the eastern and central sections of this country, the procurement of such an unpolluted supply is practically barred by financial considerations. We are therefore reduced to one of two alternatives—either to limit as much as possible, or altogether prevent, which is practically impossible, the access of impurities (notably of sewage or excremental matter) to the sources of supply; or else to resort to some method of purification of the water after it has become polluted.

The city of New York has recently chosen the first alternative mentioned, by the purchase of ground immediately bordering upon the stream furnishing the drinking water to that metropolis. By the removal of sources of pollution from the area of land so acquired, the endeavor has been made to secure a pure drinking water.

I have not at hand the figures, showing the amount of money expended in order to accomplish this purpose, but the sum must have been extremely large. In Chicago, the extraordinary outbreak of typhoid fever from 1889 to 1893 led to the extension of the in-take pipes in Lake Michigan to a distance of four miles from the shore, and the consequent diminution

of the sewage contamination has reduced the typhoid mortality from 159.7 per hundred thousand in 1891 to 31.4 per hundred thousand in 1894.

In most instances, however, where large communities are supplied with polluted water, the changing of the source of supply is impracticable. A recent inquiry by a commission of engineers upon providing a new supply of water for the city of Cincinnati, has taken into consideration a scheme for drawing the supply from the Cumberland Mountains, a distance of 130 miles away. The estimated cost of this work was \$27,000,000. Another scheme considered by the same commission, was to draw the supply from Lake Erie, 250 miles distant, at an estimated cost of over \$40,000,000. Chicago expended \$3,500,000 for the construction of the tunnel into the lake at its very doors.

These figures will probably be sufficient to show the impracticability, from a financial standpoint, of abandoning a source of water supply that may be polluted, now in use by any community, and going a great distance in search of a pure water supply. Fortunately there is at our hand, however, a means by which a source of supply once polluted can be again rendered pure; this is *filtration*.

Formerly, filtration simply meant straining out from water all gross impurities, and changing a dirty or muddy water into a clear and limpid fluid. It did not contemplate the changing of organic compounds into inorganic compounds, or the removal from the water of minute organisms, which we have learned to regard as causes of specific diseases. Our notions of what constitutes purification of water have considerably changed. We now know that water may be perfectly clear and limpid, and yet be extremely impure by reason of its content of impure organic matter or dangerous microorganisms. The results obtained by the filtration of sewage, in which a highly impure liquid, full of organic matter and teeming with microorganisms of various kinds, is rendered clear, limpid, almost entirely free from organisms and organic matter, have taught us how to purify a polluted water, which in many instances is simply a highly diluted sewage.

This method of speaking of a polluted water supply is not an exaggeration, when we study the published reports of the analyses of the water formerly used by the city of Lawrence, in Massachusetts, and now used by Jersey City and other larger and smaller communities in this country.

A great impetus to filtration was given by the experiments conducted under the auspices of the Massachusetts State Board of Health at Lawrence in that State, and carried out so thoroughly by Mr. Hiram F. Mills and Mr. Allen Hazen. These experiments, carried on with painstaking care for a number of years, prove conclusively that water, no matter how polluted, can be rendered pure by simply filtering the same through sand filters, provided certain cautions were observed regarding the construction of the filters, the rate of filtration, and other conditions varying with the character of the water to be purified.

For many years, filtration through sand has been used by European municipalities to secure purification of water. In London most of the drinking water has been filtered for upward of forty years. The filter beds of Berlin cover an area of more than thirty acres. In many of the European continental cities the drinking water is subjected to filtration. The

construction and practical management of filters have been investigated with great care. Comparative studies of the efficiency of sand filters, and of various processes of so-called "mechanical filtration," have been made recently in Providence, R. I., and at Lawrence, Mass. While the results obtained by different investigators have not been in entire agreement, the prevailing opinion of sanitarians and engineers is that sand filtration, where it can be adopted, gives the best results in purification, at the lowest cost of construction and maintenance.

Koch has given the following clear explanation of the process of sand filtration:

"The problem of filtration is to purify water from the matter held in suspension. Matter which has been dissolved goes through the filter with hardly any or with no perceptible change. As the chemist investigation of water has chiefly to deal with inquiry into the constituents which have been dissolved, it can not aid in studying the processes of filtration. But in earlier days one was so much accustomed to judge the character of water according to its chemist characteristics that, in complete ignorance of what took place in the process of filtration, one attempted to test and regulate the process chemically. Naturally, no useful result ever came of this. The specialists in filtration had found this out even in early times, and had attempted to obtain aid in some other way. They tested the water in glass or metal cylinders, the so-called 'water-tests,' as to its transparency before and after filtration, and according to the result they judged of the value of the sand filters. By this simple means they succeeded in discovering the most important conditions for a sufficient purification of water from its suspended constituents. From this it appeared that the real filtration does not take place in the sand, but that, by deposit from the still unpurified water, a layer of mud is formed on the top of the sand, and that this layer of mud which is over the sand, is the real filter which retains the suspended constituents from the water. In the process of filtration the important point is first that a proper layer of slime should be formed, and that it should not be disturbed during the process of filtration, and that when by further continuous deposit it becomes too thick and therefore too impermeable to water, it should be removed. According to all appearance different natural waters are capable of producing the filtering mud layer in very different degrees, according to the amount of mineral and vegetable matter held in suspension. Some river waters which are especially rich in clayey constituents can deposit a good filtering mud layer in eight or ten hours. Other kinds of water rendered more turbid by vegetable matter require a longer time, at least twenty-four hours, to form the deposit. At certain periods of the year, especially at the time of the so-called 'water-bloom,' owing to the appearance of innumerable microscopic algae, the vegetable constituents suspended in the water are increased to an extraordinary extent and are of a particularly slimy character, and form therefore a layer which in a few days becomes nearly impermeable to water and must be removed. From these brief remarks it will appear that in sand filtration we are not dealing with so simple a matter as is often supposed. It has also been discovered that in the gradual wearing out of the sand layer it should never be allowed to get below a certain thickness, about 30 cm., and that a certain speed, about 100 mm. in the hour, must be allowed

for the movement of the water through the sand layer to obtain the most perfect purification."

Koch further states that a daily or tri-weekly bacteriologic examination of the filtered water must be made in order to test the performance of the filter. "If a filter works satisfactorily in every respect, experience shows that there will be found less than one hundred germs capable of development in one cubic centimeter of water; and this is irrespective of the number of bacteria contained in the water before filtration." The slightest changes in the rapidity of filtration, or the disturbance of the filter bed, become manifest on bacteriologic examination.

The cholera epidemic in Hamburg in 1892 furnished an object lesson of great value. Hamburg and Altona both draw their water supply from the river Elbe. In Hamburg, in 1892, the water was furnished directly to consumers without filtration; in Altona, on the other hand, the water had been for a number of years filtered. The Hamburg supply was drawn from the river at a point where there was comparatively little pollution, but the Altona supply was drawn from the Elbe immediately after the stream had received the sewage of the entire population of Hamburg, numbering nearly 800,000. As a matter of fact, cholera bacteria were discovered in the Elbe water below the main outlet of the Hamburg sewers. There was every reason to expect, therefore, that the cholera would have been more virulent in Altona than in Hamburg; but the contrary was the case.

In Hamburg about 21,000 persons were attacked by cholera, of whom over 11,000 died during the epidemic. In Altona, on the other hand, there were not over 500 cases—400 of which were shown to have been importations from Hamburg, thus leaving the small number of 100 cases traceable to infection in Altona, or unaccounted for. Koch, who made a very careful inquiry into the circumstances of the outbreak at Hamburg, came to the conclusion that the comparative immunity of Altona was due to the filtration of its water supply.

Returning to the consideration of typhoid fever, we have in the United States an example of the limitations of this disease, produced by the purification of the drinking water by means of filtration. For a number of years, the city of Lawrence in Massachusetts had suffered from typhoid fever to an unusual degree. For the six years from 1887 to 1892, the typhoid deaths in that city averaged fifty annually, a proportion of 119 per 100,000 of population. In 1893, the drinking water, drawn from the Merrimac river, was subjected to filtration, and at once the typhoid death rate began to fall. In 1895, two years after the filtered water had been in general use in the city, the number of deaths had fallen to sixteen, of which nine occurred among "operatives working in certain mills where unfiltered water was used for washing purposes, and was used for drinking by the operatives, notwithstanding the prohibition of such use, because the river water was more accessible than the city water." (Quoted from a paper by Mr. Allen Hazen in the *Health Magazine* for March, 1896.) In two cases, the disease was believed to have been imported, and in five, the origin was not accounted for.

The conditions, under which filtration takes place, have been studied particularly in the experiments made at Lawrence, above referred to. Without going further into the details of the construction of filters, two processes must be kept in view—one, the removal

or straining out of the bacteria, always present in water; and the other, the oxidation of organic matter, and its conversion into inorganic compounds. These imply, that the materials, of which the filter is constructed, shall be sufficiently fine to hold back all suspended matters, and that a sufficient supply of oxygen shall always be present, in order to allow the oxidizing processes to go on. In most natural waters there is a sufficiently large quantity of free oxygen to allow the oxidizing processes to go on continually, but in cases where the water is highly polluted, it is necessary to permit access of extra quantities of oxygen, in order that all the organic matter may be oxidized. This may be accomplished, either by aeration of the water before filtration, or by carrying on the filtration intermittently, allowing the air to penetrate the interspaces in the filter before the water is again turned on the filter. This is in effect what is done in the intermittent filtration or the broad irrigation of sewage.

In the experiments at Lawrence, it was found that an average of 98.54 per cent. of the bacteria found in the river water were removed by filtration; under favorable conditions, *i. e.*, with filters of the best construction, and a moderate rate of flow—less than 1 per cent. of bacteria remained in the water after it had passed through the filter.

Within the last two years an extended series of experiments upon filtration with so-called "mechanical filters" were made in Providence, R. I., with the view of adopting a system of filtration combining efficiency with economy. The apparatus most thoroughly tested is known as the "Morrison filter," and its construction is described as follows:

"The filter bed of crushed quartz was two feet, ten inches in depth, supported upon a base of iron with circular perforations of about four inches in size, which were covered with screens. The crushed quartz used was the 'effective size' of 0.59 millimeters. The filter was washed by a reverse current, which caused the quartz to boil. The agitation and friction of the particles were increased by means of a rake with long teeth, which revolved about a central column in the filter; the rake penetrating the bed by a screw motion from top to bottom." One-half grain of basic sulphate of alumina was used to the gallon of water filtered, in order to produce a film upon the surface of the filter. This constitutes the real filtering layer, corresponding to the mud layer in the natural or sand filter.

The results obtained in these experiments showed that with careful management, from 92 to 99 per cent. of the bacteria contained in the water could be removed by mechanical filters. Further investigation demonstrated, however, that the installation and management of these filters would be more expensive than sand filtration, with no increase in efficiency.

On the whole, it is probable that sand filtration, having been thoroughly tested both by experiment and practical experience, must be regarded as the most efficient method of purifying a polluted water supply; and that, when carefully and intelligently managed, it can be depended upon for purification has been shown in the experience of Altona and Lawrence.

Did Not Know Him. Professor Giesler, of Göttingen, has twenty-four children. He saw a child crying in the street and asked: "What is the matter, little boy?" "Don't you know me, papa?" said the boy. He was one of the twenty-four.

CONCERNING MEDICAL LANGUAGE.

Delivered at the Meeting of the American Medical Editors' Association,
held at Atlanta, Ga., May, 1896.

BY GEORGE M. GOULD, A.M., M.D.

PHILADELPHIA, PA.

One of the most amusing inconsistencies of a small class of minds otherwise progressive, scientific and rational, is their unreasoning conservatism concerning the spelling and use of certain words. In any other subject, for instance therapeutics or surgery, they will welcome investigation, and further it, admitting the duty of improving upon the old, and of pushing on toward a more simple and perfect science. But when you suggest that language, the tool of thought, deserves consideration, is very clumsy and archaic, is capable of being improved—at once they shrink and are shocked at your temerity.

This attitude of hatred of innovation in one single field of human activity, while admitting the law of progress in all other departments, is also coupled with a second inconsistency; a dogmatism of conviction that the change or modification of language urged is barbarous, almost sacrilegious, that you are a sort of ill-bred upstart in advocating it, and that the old form you desire to supplant is the correct one, while your new-fangled thing is absurd and is born of ignorance. The bigotry of the average Englishman in these matters is a charming exhibition of medieval-mindedness translated to an age of civilization and progress. He actually thinks that the spelling-reformer, however infinitesimal and microscopic the spelling-change advocated, is the product of "Americanism," and of American ignorance of how to spell. The American inheritor of the English dogmatism tries to hide his feeling, shrinks from such laughable exposure of his own ignorance, and even covers the sheep-skin of his ignorance with the lion-skin of erudition. I shall not soon forget a contributor whose English was equal in barbarity to that of our average senator, whose spelling by any standard was atrocious, and whose medical ideas were of course on a par with their means of expression; but he was certain of one thing, that he wanted hemorrhage "spelled rightly, with *e*." This to him was the symbol of scholarship—his nose was safely in the sand of erudition, but his whole body was delightfully visible.

I have had the pleasure of replying to but three or four critics of a few tiny philologic reforms or changes that seemed to me wise. Beside these four the world seems content either to accept or to reject in silence. I was struck by the fact that in all four of the speaking objectors their objections were solely based upon two foundations: Their personal dislike of change, and their complete ignorance of philology. Concerning the argument, *de gustibus*, there is surely no discussion, because taste, proverbially, is simply a subjective affair. But dogmatic opinion upon a subject in dispute, the deeply-rooted dogmatism upon things without a single minute's study of them or of their history—this in a supposably scientific man is—well! let us call it deplorable. It is amusing, even instructively amusing, but it is, once more, deplorable. Such a person, if a surgeon, would be shocked if you asked him to pronounce dogmatically upon an unstudied question of therapeutics or of mental disease, or if a diagnostician he would not express the least judgment as to cataract extraction, etc., but without an instant's study of philology he settles a philologic dispute off-hand and forever. Five minutes of glancing through

any one of the hundreds of books on the subject would have closed his lips, but that does not give him pause. He is sustained by the fact that "the English language as now written is good enough for me," and there float through his mind hazy ideas that etymology demands the present method, and that at best you are a very bothersome and conceited person.

To one who has pondered the subject, however little, it must be painfully apparent that every other product unconsciously developed in the evolution of the race, whether plows, guns, matches or books, has been found capable of betterment, and all civilization consists in improvement of or improvement upon the crude devices of early awkwardness. Why should language then be an exception to the rule? Those who have examined carefully aver that our language is a sorry instrument of thought, and bears about the same likeness to an ideal language that a hand-sickle does to the best reaping and binding machine of our day. It is plain, therefore, that the obstinate prejudice against any change whatsoever in it is most ill-advised and unreasonable.

We do not advise radical changes. The proper attitude of mind is one that welcomes slow and slight changes toward shortening and thus lessening the severe burden of education, and the expense of printing. Reform has a double motive here, psychologic and commercial. It has been estimated that our outrageous spelling costs one year of school-life of every child. The financial saving by lessening every printed page one line would probably pay the expenses of our government, and perhaps retire on a life-pension the Senate besides. This line could be saved, and at least a day or two of the wasted school-life spared by abolishing *æ* and *œ*, by lopping off a few redundant tails of words, and by observing a half-dozen little rules—all of which are not only advisable but philologically necessary, not only not improper but genuinely proper.

As to *æ* and *œ*, these diphthongs are difficult to write, and they are against the genius of the language. They have already been sloughed in a large number of words, and those who oppose what they are pleased to call "the mutilation of our beloved language," must answer our demand for a rule. Shall we reinsert the *æ* and *œ*, in words at present spelled with *e*, and which were derived from older words spelled with the darling diphthongs? And if you spell *hemorrhage*, will you, as you should, pronounce it hē'-mor-āj? It seems to me the etymologic sticklers are false to the old love, however true they may be to the new. Most of our words, for example, beginning with *præ*, are derived from the Latin *præ*. There are possibly a thousand of these words, such as *prescription*, *prepuce*, *pretend*, *preference*, etc. Shall we spell them all *præscription*, *præpuce*, etc.? Shall we also be (etymologically) correct and write *hæresy*, *hæretic*, *anapest*, *peony*, *phenomenon*, *meander*, *hematite*, *æther*, *dæmon*, *æsthetic*, *apheresis*, *diæresis*, *archæology*, *palæography*, *gangrene*, *pædobaptist*, *cannibite*, *cemetery*, *celestial*, *æconomy*, *epicæne*, *æsoptagus*, *phœnix*, *solæism*, and hundreds of derivatives and similar words as they are here written? Will you spell *diocese*, *diocese*? Will you spell *fancy*, *frantic* and *frenzy* with a very etymologically proper *ph*, instead of an incorrect *f*? If so, your phancy will make your readers phrenzied, and you phrantic, I fear. Will you write *fansy*, *treacle* and *treasure* with a *th*? If so, lay up your threasure in heaven, and

drink much threacle and thansy while your days do last.

Etymologic spelling is a long-exploded absurdity. It has led many a poor word-grubber into the quagmires of absurdity. It was, says the great English etymologist, a sort of mania in the sixteenth century, and has thrown confusion and ridicule into the study of language. "Its ignorant meddlesomeness introduced many false forms," so that now hardly any word tells its genesis or history by its written form. Every word must be examined separately, its changes both of form and sound must be studied historically, before we can know much about it. The final dictum of Skeat is as follows:

"The shortest description of modern spelling is to say that, speaking generally, it represents a Victorian pronunciation of 'popular' words by means of symbols imperfectly adapted to an Elizabethan pronunciation, the symbols themselves being mainly due to the Anglo-French scribes of the Plantagenet period, whose system was meant to be phonetic. It also aims at suggesting to the eye the original form of 'learned' words. It is thus governed by two conflicting principles, neither of which, even in its own domain, is consistently carried out."

It may be said that as many of our medical terms are not derived from the Greek or Latin by a real and historical process, but are *de novo* creations, using the ancient roots and stems as convenient materials of coinage, the objection does not hold, and that our words do therefore show their originals by their form. Alas! not even this poor excuse bears scrutiny. The centuries have infected the modern word-minter, and the inevitable hurry and destiny of evolution will not let the need of condensation rest. Even while we look at our printed dictionary the Zeitgeist is telescoping our words. Who now says *thyreoid* and *chorioid*? These forms are perfectly proper, and your dictionary-man with the awful sword of "etymology" and conservatism held across his path may be forced to write them so, but he smiles sadly as he does it and shakes his head despondently. Every one of the hundreds of words ending in *-oid* is derived (supposably) from the Greek *αἶος*. Why, then, is it *-oid* and not *-eid*? *Bulb* and *Bulbar* should be *both* and *bolbar*, as they come from *βολβος*. *Croup* is from A. S. *kropian*. How can an etymology-lover write *hyoid*? What resemblance is there to the Greek word? Our convenient compound word should etymologically be spelled *thyreo-hyacid*, instead of *thyreo-hyoid*. Why is one who forbids one literal iota of change in present words so utterly indifferent about the changes that have already crept in in the past? There are thousands of words in which Greek *i* has been changed to English *e*, as, e. g., all the words ending in *rheum*. He is wrathful because one wants to change them to *rheai*; why not so to those who changed the original *i* to *e*? He is as idolatrous of his beloved thousand *harms*, but the Greek was *hai* and not *har*. One of the most ludicrous instances of this imaginable is the very new coinage which its author spells *cardiology*. The anger of enraged Jupiter was as nothing to that aroused by the suggestion to shorten it to *celiology*. But in that word as given out, there is, "once you trip on it," perhaps not "twenty-nine," but at least two or three "distinct damnations, one sure if another fails." Why in the name of holy etymology, if derived from Greek *καλῶ* do we have *e* instead of *k*, and why *car* instead of *coi*? If the *calia* is derived from the Latin, then

why the hybrid? Surely one who pretends passionate devotion to pretty Ettie Mollie G., must not at the same time be paying court to her hated rival, the little illegit Miss Hybrid!

Every page of the dictionaries proves the absurdity of trying to make spelling teach etymology; and it is a fact that not anybody, certainly not spelling-reformers, more certainly not the conservatives, cares two beans for the etymology. If we did not have the printed word to stamp the coin it would be a different matter, but with dictionaries everywhere to give the origins and histories of all words, what imaginable service or usefulness is there in the attempt to load each down with its biography? In reading or speaking no one can think or wishes to think of the root thousands of years old. As well demand that your bouquet of roses shall have their roots and soil. The investigating botanist may do so, and may know all about the root and branch and stem, but work-a-day folks are not botanists or radical philologists. If one in reading had to know or keep in mind a half-conscious recognition of the etymology of each word, he would be able to read about one book a year, civilization and science would stagnate, and we might, could, would, or should all become Congressmen, millionaires, or jingoes.

The only proper and sensible purpose of spelling is its phonetic purpose. All the philologic tories of all Christendom or heathendom combined can not prevent the inevitable modifications—even entire changes of the spoken sound. In that witches' cauldron of modern English, especially the medical variety, we have from every source cooked a most remarkable hodgepodge of illogic and inconsequential conglomeration. Our ancestors have commanded us to eat of it, but do not let us choke it down, hiding our tears of disgust, and vowing it is incomparably toothsome. We assuredly should not with glee add more of the worst to the olla podrida, and when we have a justifiable opportunity to make it a millionth part better, we should not set up a cry of revolt, and cry, sacrilege! In an African forest the trail or path-way has constantly recurring detours, angles and curves, so that one walks about twice as far as necessary to reach land's end. No object prevents following a straight line. Why is this? It is because once a tree blew down here across the path, there a limb broke off, there a stone rolled down. So the savage went around these objects, forming a new and crooked path. When the termites devoured the tree the new trail was more worn than the old one, and with thoughtless imitation the men kept on laboriously winding and twisting their way instead of going straight on and across. It is the barbarian's habit of mind to keep on the unreasoning way his predecessor traveled. It is the essence to make straight the way. The incongruities of medical nomenclature and the stock-still standing of irrational conservatism lead one to wonder if we are ever to awaken to the need of philologic civilization. No judicious reformer asks for revolution but for evolution; we need be in no hurry; we should not make profound or radical changes, because (and only because) it is impossible to bring them about; but when men oppose every jot and tittle of change, when they fight against one single conscious change of precisely the same kind as

¹ Another sorry neoplasm is *uranalysis*—"analysis of ur"—to replace an equally absurd word, *urinalysis*—"alysis of urin." We have looked in vain for the words *olysis* and *ur*.

has already been a thousand times unconsciously wrought, then surely one must with open-eyed astonishment ask: Really, now, were you not born in Africa?

I wish again to emphasize the limitation that we do not advise one clean straight jump into phonetic spelling, simply because it is impossible. We seem like some mothers—the uglier and sicklier our orthographic child the more we love and cherish it. The maternal love is wise, but the other is a mania. Turn to Germany and what do we find? So far as phonetic writing is concerned their language was already marvelously perfect, but because it was not entirely perfect the Germans within a few past years have made it so. With us, whose spelling is the butt of the world's ridicule, with us we shriek our parrot-anger or growl our ursine bigotry if one suggests lopping off a supernumerary finger from our hideous teratologic thing. What kind of a nation is this Germany? Well, for one thing, she delights to pay her debts with value-received, while another nation we know of, from the hollows of lost manhood and polite poltroonery, squeaks and squizzles its senatorial sixteen to one. Another thing about this foolish Germany is that when a foolish nation attacks her, at once her edict of blood and iron goes forth, and in a hurricane of heroic energy her legions sweep resistless over a conquered land into the capital city of the world, and crown her emperor there in the coronation halls of dead Bourbonism. How is it with another nation? To show our braggart boorishness we intermeddle in another nation's rebellion, or we espouse the cause of a half-barbaric folk thousands of miles away, for whom we do not care a fig, against the world's one great civilizing and colonizing nation, and with a corporal's guard of 25,000 soldiers cry, War, War, War! How is it with Germany as to science generally, and education, and especially as to medical science? The thousands of our young men sent to her laboratories is sufficient answer. Well, this nation, as I have said, in a few years, and at one sweep, has cut the Gordian knot of spelling, simplified and shortened education thereby, and while we are squirming and making wry mouths over a few paltry and insignificant changes, she has wholly reformed the language that Goethe and Lessing wrote.

One of my four kind critics once wrote me remonstrating solely, on the ground of euphony, against cutting the *-al* off the tail end of many adjectives: "He didn't like it," he said, "it didn't sound well." He seemed wholly forgetful that the over-long tail of a thousand such words had already been lopped off, or perhaps had never grown out. In some countries the sheep's tails are so long that they hitch a tiny wagon to each animal, so that it hauls its caudal extremity instead of dragging it on the ground. Now the difference between these sheep and our medical Bo Peep *al-pacas*, is that the words grow no valuable wool on their tails, and that we trawl them on the ground behind us as the ladies do their dress-trails. Sheep and words and ladies are alike in the one important respect that, in the poet's immortal lines, we let them alone and they surely come home, dragging their tails (and much else also) behind them.

To my genial critic who wished his words and sheep (his ladies, too, I wonder?) to have tails and trails twice too long, I sent the following skit, to illustrate the already recognized fact of the redundancy of many

word-tails, and to suggest that we either retail all the short-tailed curs, or that we curtail all the long-tailed puppies. Either one thing or the other; if you refuse to say *chemic* and *theoretic*, then you must not say *scientific* and *hydrochloric*. If you make us say *chemical* and *theoretical*, then, like a sucking dove we will roar you for consistency and ask that you be *scientific*, or else we will prescribe *nitric* and *hydrochlorical* acid for your alarming *gastrical* torpor and obstinacy. My strabismic letter to my friend was as follows:

SOME SCIENTIFICAL DIFFICULTIES.—The patient was at the Polyclinical Hospital—a very sick man; he was ascitical and cyanotical; he had an anemical (dirotical or anacrotical) murmur; splanchnical and splenical dullness was pronounced. Neither the allopathical nor the homeopathical consultants could determine whether the affection was of extrinsical or intrinsical origin, whether anabolical, katabolical, atrophical, septicemical, lithemical, luetical, hemical, hemolytical, thermal, tabetical, hepatical or encephalical. The specialists were called in, and laryngoscopical, ophthalmoscopical, gynecological and otoscopical examinations were made. The laryngoscopical man said a diphtheritical membrane was forming, and the phrenical nerve was pressed upon. The next averred the difficulty was esophorical or exophorical, that a blennorrhagical inflammation, perhaps a rheumatical iritis existed. After an endoscopical examination the gynecological expert said pelvic (or pubical) disorder was present, and a bad cystical, spermatical and chorionical state of affairs. The ear-man claimed that the disease was specifical, that the otical ganglion was syphilitical and its condition pathognomonical. The diagnostical and prognostical difficulties were certes becoming most prolific!

As to therapeutical measures, one advised cardiacal and tonical treatment, another hypodermical; one thought hydriatrical methods good, another antiphlogistical, while still another suggested hypnotical and soporifical agents. Galvanical and faradical electricity, as well as statical and franklinical, were advised. The surgeon after a diagnostical incision (under anasthetical precautions) spoke of a plastical operation. Caustical applications to the throat were considered good, and the exhibition of prussical, or of borical, nitric and hydrochlorical acids, perhaps also carbolical with malical and acetical acid drinks. The general physician thought antineuralgical and antirheumatological prescriptions sufficient, but the obstetrician would have added oxytocical ones.

The patient died of *al-coholical* parietal dementia, superinduced, it is thought, by despair at the orthographical and phonetical conservatism of progressive Americans.

To make short work of it, the essence of the matter concerning *-ic* and *-ical* is this: Both of the suffixes, *-ic* and *-ical* are terminals, the significance of which is to give an adjectival meaning to a word. To add them both to one word is to contend that dogs and sheep should either have two tails, or that one tail should be twice as long as normal. If the suffix, *-ic*, gives the adjectival meaning, why add a second? The French, from whom we get many of the *-ic* terminations, find it unnecessary to add an *-al*. If a word is an adjective can you make it more so by tautologic caudalizations? (There are a few words whose stems end in *-ic*, such as *vesical*, *clinical*, *logical*, *finical*, etc., and these require the *-al* to make them adjectives; but these are provings of the rule, and the query why you don't say *vesic*, *logic* and *clivic* is the prompting of thoughtlessness. I would not object, however, in the least to clipping these also.) If a word needs two adjectival tails why should we not say *bestialic*, *linealic*, etc.? If these were admitted of course the *-al* lovers would have to add their pet to the word, and we should have *bestialical*, *linealical*, etc.; each sheep would then require two toy-wagons. This reminds one of the wonderful word, *pocket-handkerchief*. The primary good word was *kerchief*, a head-covering. We now call a piece of lace or linen a pocket-hand-head-covering. I am not unmindful of

the hyperfinical distinction that some hyperfinical folk have sought to establish as regards *-ic* and *-ical*, *-ac* and *-acal*, that the *-ics* and *-acs* denote primary objective attributes of or pertaining to the things, whilst the *-icals* and the *-acals* denote secondary qualities—of the nature of or connected with the attribute in *-ic* or *-ac*, i. e., more remotely and subjectively relating to the thing. For example, a *cardiac valve*, the *cardiacal qualities* of a drug; a *historic answer*; a *historical treatise*; a *comic paper*; a *comical idea*. But this contention is impossible of realization—1, because hundreds of words by custom have become absolutely limited to either form singly and alone; 2, because not even the best writers observe the distinction; 3, it is altogether too fine a distinction to be made by the ordinary workaday humanity; 4, it would not satisfy the *-alophiles*, who want the *-al* on the end of some of their words, without question, forever and ever, world without end, Amen! Think of saying *Arabical*, *Teutonical*, *Celtical*, etc.! We should of course have to adopt *beastialic* and *beastialical* (or bestic and bestical), *clinic* and *clinical*, *syphilitic* and *syphilitical*, and so on to the end. It is quite plain this system-mongering and analogy-craze leads us into sorry plights. In fact, it should be apparent upon a minute's reflection that in a language so utterly composite, illogical and non-systemic as ours, the argument from or for analogy is absurdity itself. In one respect this is an advantage, because when we can succeed in battering down the dead wall of ancient prejudice, and explode the arsenal of etymological spelling, then we may bring some order and sanity in the rebellious mob of English words.

Of one thing we may rest assured: All the tory immobility of all the world can not prevent change. It is as useless to attempt it as to try to stop the rising tide, or to stay the resistless and silent forces of evolution itself. It is the part of wisdom to guide evolution, not to fight it to the death, to guide language-evolution in the interests of brevity and perspicacity, not to cling irrationally to the old ways which clear vision may clearly see are doomed. The language of Chaucer, and even of Shakespeare, as shown in the original forms, is an utterly different language from that we speak to-day. The ordinary American, if he could hear Chaucer speaking, or if he could listen to a phonographic repetition of his actual speech, could not understand a sentence, hardly a word of it. The printed form can not bind the ever-fluctuating pronunciation. The province or function of the printed (or written) word is to stand as a symbol or visible analogue of the spoken word. Etymology to the dogs! Printing makes certain a record of the etymology, but to seek to clog the word itself with it is the worst of delusions. Our duty scientifically, sociologically, and philologically is to keep the printed form plastic. The crystallized language is a dead language, and when there is no plasticity of language there is none of the minds and civilization of those who speak that language. There is a subtle, but all-powerful reaction and retroaction of language upon mind. Men progressive in science and sociology must be progressive in language and the use of language. Prick a German word and it bleeds. There is the pulsing heart of meaning behind it, flooding it with sanguine significance. French words, and the Greek-derived or Latin-derived words of our own tongue are as bloodless, dead and meaningless as are to us Chinese pictographs. The comparison of the large, plastic, ener-

getic, capable German with the narrow, crystalline, stationary, incapable Frenchman must at once spring into view, and the prophecy is clear as to which one is to inherit the future. The French birth-rate is about equal to the death-rate; that of the Teuton is far in excess. Do you believe in progressive Teutonism and Anglo-Saxonism, or in reactionism, toryism, and ultramontism? Choose your partners, gentlemen. Your choice in so little a matter as the use of words will tell the plain story of mental bias, quite as well as the choice of religion or of political party.

Specifically, the microscopic modifications I have urged here are as follows:

1. Abolish in English words the archaic, unnecessary, bothersome *æ* and *æ*, supplanting it by *e*.

2. Cease adding the tautologic *-al* to adjectives having already one adjectival suffix, *-ic*. It is already done in thousands of words; finish the job.

3. Drop the useless hyphen in words whose parts are derived from classic languages. In ten thousand words you have already done so; finish with the rest. But retain the hyphen in such compound terms as express a single idea by two semifused English words, especially when both are nouns. E. g., say *antitoxin* (not *anti-torin*), *culdesac* (not *cul-de-sac*), *postmortem* (not *post-mortem*), *centrofixation* (not *ventro-fixation*), etc. Keep the hyphen, because it is necessary to avoid confusion and doubtfulness of meaning, in *curet-spoon*, *heart-murmur*, *skin-disease*, *sleeping-sickness*, etc.

4. Drop the useless *-te* from *curet*, *brunet*, *fouret*, *etiquet*, *cigaret*, etc. You have already lopped it off from *culet*, *doublet*, *quartet*, *quintet*, *sixtet*, *septet*, *racket*, *minuet*, *fillet*, *corset*, *stylet*, *tourniquet*, *bouquet*, etc. Finish the job.

In the same way cut off the useless *-me* from many words, writing *program*, *gram*, *centigram*, etc., just as already we do *telegram*, *anagram*, *diagram*, *epigram*; let's make an end of it.

5. Use figures instead of spelling out numbers, at least those above ten.

6. Anglicize foreign terms when a goodly proportion of your readers will not understand them in the originals. Use italics as little as possible; use as few foreign words and terms as possible, because the vast majority of your audience can not understand them (even if *you* do); and because there is a deal of silly conceit in airing exotics of speech.

7. As to the spelling of chemic terms, accept the recommendations of the American Association for the Advancement of Science, which after years of dispassionate investigation advised that we drop the final *e* in *bromid*, *iodid*, etc., and in *bromin*, *iodin*, *atropin*, *quinin*, etc. Say *phenol* instead of *carbolic acid*, *glycerol* instead of *glycerin*, etc.

8. Abolish all diereses and accents. They can not teach pronunciation, and they are useless luggage. Let us write *oophorectomy*, *cooperation*, *ptomain*, *leukomain*, etc., without the diereses. When a foreign word is Anglicized let us do it completely, and not drag over into our domain the exotics of foreign habit, leaving it, e. g., neither English nor French. Leave to the poets the acute, the grave, and the circumflex accents, that are foreign to the spirit of our own tongue.

9. Do not bother about hybrid terms. A mule is a better animal than either its father or its mother. It is only finicky sticklers that are horrified by hybrid words. There are many, many thousands of them in

our language, good words too, that have been used for centuries, and that always will be used. There is no earthly objection to them,—and indeed, we should rather welcome them if they are good words, expressive and short. More than any other language ours is adapted to receive them and use them, and there are more of them in it than in any other language. Instead of being ashamed of the fact we should be proud of it, as it shows our receptivity and plasticity. If we are bound to have the defects of our virtues, let us not be ashamed of the virtues of our defects.

Finally, I would beg that you carefully consider the source and secret reasons that exist for opposition to the foregoing recommendations. Ignorance, colossal, imperturbable, impertinent ignorance is characteristic of much of it. Read, for example, the letters in the *British Medical Journal* from correspondents (not editorial utterances, because the editors know better, and have publicly advised dropping the *æ* and *œ*), and you will see these objectors haven't studied philology five minutes in their lives, and are living in an antediluvian world.

But, again, consider the source, I beg of you, and you will very often find that it is the secret influence of the commercial medical publisher that is at work. He publishes a dictionary committed to the old ways, and hence prints his medical journals and books in the archaic language of his dictionary. It means expense and loss of money to him in very many ways to have his "authorities" supplanted. The astute editor of the *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* has caught this aspect of the matter, and an editorial in the issue of Feb. 8, 1896, happily sets it forth. It becomes an important concern of the profession whether it has any scientific and literary rights, and if it shall govern itself or be governed by its publishing servants, very accommodating editors, and self-interest generally. What an instructive fact it is to see a journal that has once been taught how to spell, go back under the domination of commercialism to the "flesh-pots of Egypt." In this connection it is worthy of note that the two considerable journals of the United States *not* controlled by the commercial publisher, the *Boston Medical and Surgical Journal* (representing the best literary and scientific culture of the Eastern States) and the *JOURNAL OF THE ASSOCIATION* representing also the enterprise and freedom of the Western and of all States have long ago adopted and do now use the more progressive methods of spelling. The same practice on the part of many other reputable journals, and the unanimous acceptance of it by the American Medical² Editors'

² From *The Medical News*, June 17, 1893, I reproduce from the paper read at the meeting of the American Medical Editors' Association in Milwaukee, June 5, 1893, the following sentences:

(a) Of all the languages of the civilized world there is none that in the most distant manner can rival the English in the ludicrous illogicality and wretched lawlessness of its orthography. In other languages there is a manifest philologic sanity that evidently seeks to hold the written (or printed) word in some sort of relationship with the spoken word. But in our language the reverse seems to be the case; the more methods in which a single sound can be spelled the better it seemed to please the fathers of the language. As Professor Lounsbury says: "There is nothing more contemptible than our present spelling, unless it be the reasons usually given for clinging to it."

(b) The labor which this fact imposes upon the child's mind, and upon all minds that, so far as language learning goes, persist in the prepubertic stage, is a labor that conceived in its entirety is literally appalling. The German child learns in one year, and well, what the English child learns in three and poorly.* It is so tremendous a labor that even few educated men reach unconsciousness and ease of orthography, and for the great mass of people it is a constant source of worry or chagrin. To a vast number of people the secret consciousness of

Association three years ago—these and more, are most encouraging proofs of our freedom from prejudice and dogmatism, and that we are alive to the demands of literary as well as scientific progress. The suggestion need hardly be added that as without payment we give our articles, the product of our laborious lives and our devotion to nonmedical men, out of which they make fortunes, it hardly becomes them to dictate to us as to literary and scientific matters. If you contribute to these journals you have a perfect right to demand that your ideas of language shall be followed in their printing. Accompany your article or book with the condition that your choice of spelling-methods, etc., be carried out.

their orthographic failing keeps them from the pleasure of writing and composition, or prevents them from profitable employment. To every person that writes, the excess of labor required by our barbaric spelling is a huge waste of time and a heightener of the friction of life. With the correlated barbarism of pronunciation, it is the greatest obstacle to the spread of English as the world's great, sole tongue.

(c) The foregoing facts are so incontrovertible that no one who has even cursorily looked into philology and pedagogics has any tendency to deny them. Equally certain is it that all of our great students and masters of philology are entirely agreed as to the tremendous importance of lessening the burdensome labor of education, and the friction of life, by some approach, great or little, toward the phonetic spelling of English words. As succinctly stated in his preface by the learned editor of the great *Century Dictionary*: "The language is struggling toward a more consistent and phonetic spelling, and it is proper in disputed and doubtful cases to cast the influence of the dictionary in favor of this movement, both by its own usage in the body of the text, and at the end of articles by the order of forms or the selection of the form under which the word shall be treated."

Never has more capital been invested in similar enterprises, and never has more philologic erudition been gathered to the service than in the editing and publishing of those splendid lexicographic monuments of American scholarship, the *New Webster*, the *Century* and the *Standard* dictionaries. It is equally true that in each case the most earnest desire of the men in charge of these works has been to go to the furthest admissible limit dared in recommending the shortening and rationalizing of the spelling of English words. They have only stopped when and where they thought further advance would result in a balking, and a refusal of the people to follow.

Words fail me to express my amazement to hear men object to all change in the customary spelling. To be sure, they are but few, and those who have never given the matter an hour's thought or study, who thus blindly cling to the fetich of custom, stolidly resisting any change whatsoever. The changes that have been made, and that have become the rule—these they willingly accept. They have grown used to spelling *music* and *public* without a final *k*, and are willing to leave off this useless second tail. (The English even now stick to the final *k* in *almanac*.) But their mental forefathers as stoutly resisted the curtailing process, and their similarly minded children will finally accept the changes that progressive minds are now forcing on their fathers. The stupidest, most disgusting thing in the world, is the brute conservatism that refuses all change, good or not good, from stolid, unreasoning desire for things as they are. Better chorea, ay, better epilepsy than absolute paralysis. Conservatism is the sham coyness of linguistic old-maidism, the crinolin fig-leaf of philologic prudery, a fig-leaf, too, not the result of too much, but of too little knowledge—indeed, of an abysmal ignorance of the history of the language.

And most strange of all is such a dead-blank wall of prejudice on the part of medical men. Their science is a progressive one; their life is harassed and hurried with the crush of duties and opportunities. Every hour's experience teaches them to ignore precedent and to cut by the shortest route to the desired end. No body of men is more hampered, and in no calling is labor so much thwarted as in theirs, by popular inherited prejudices, and the old unsloUGHed snake-skins of quackery, of myth and of mummery.

The vast majority of medical words have not grown out of the old languages, either of the ancient living Greek or of the mediævally preserved dead Greek. When a word is desired the modern minter snaps out his Liddell and Scott, gets some words that best suit his purpose, and shakes them together in his etymologic basket until they cohere into some sort of unity, not infrequently a very ludicrous one.

The argument most relied on by the obstructionists is the etymologic one. But even this poor scarecrow can not be set up in our medical cornfields. I do not think the etymologic argument of much force, even in the general literary language, because already the form in a large portion of our words is altogether misleading, changed, or lost, and because the vast majority of people will and can never know anything of the etymologic rootings of their language. But far more important still is the fact that with printing came the impossibility of a coinage ever being lost, its history unrecorded, or its tiniest rootlet unexpressed.

But far and away over all is the fact that the needs and the help of the living millions of bodies and minds present and to come outweigh linguistic and philologic considerations. Language was made for man, not man for language.

Moreover, and this note well despite all the literary coxcombs and philologic old maids of Christendom, reform is inevitable. The people, with unerring instinct, are determined to mold their language into some better conformity to their needs. Slang is riotously rampant, and slang is language in the making. Some reform in spelling is as certain to come as future men and women are certain to come, and wisdom on our part is to accept the inevitable, and to make that inevitable as sensible as we can. As another has said: "The grammarian, the purist, the pernicketty stickler for trifles is the deadly foe of good English, rich in idioms and racy of the soil."

* Professor March says that "it has been computed that we throw away \$15,000,000 a year paying teachers for adding the brains of our children with bad spelling, and at least \$100,000,000 more paying printers and publishers for sprinkling our books and papers with silent letters."

Information Wanted.—Why is it ethical to prescribe German patented medicines and boycott the standard products of American chemists?—*Medical Brief*, December, 1895.

CHAIRMAN'S ADDRESS.

Address of the Chairman of the Section on the Practice of Medicine, delivered at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY WM. E. QUINE, M.D.

PROFESSOR OF THE PRACTICE OF MEDICINE IN THE COLLEGE OF PHYSICIANS AND SURGEONS OF CHICAGO AND PRESIDENT OF THE FACULTY.

THE REMEDIAL APPLICATION OF BONE MARROW.

For the original mention of bone marrow as a possible remedy we are indebted to Brown-Séquard and d'Arsonval who, in 1891, suggested its use in the treatment of leukemia and other diseases believed to be characterized by defective hemogenesis. A year and a half later Filleau reported its successful employment in the form of an extract, in the treatment of the anemia of debility and of tuberculosis; and Macalister recorded a favorable result of its use in one case of lymphadenoma. (*British Med. Jour.*, June, 1893.)

It was left for T. R. Fraser, of Edinburgh, however, to press the new remedy forcibly upon the attention of the medical world and this he did in a report of its curative effect in a case of progressive pernicious anemia. (*British Med. Jour.*, April 7, 1894.) The clinical phenomena described were those of extreme anemia and the diagnosis was based on repeated blood examinations. The treatment included the use of arsenic, iron and salol, part of the time, but no improvement was noted till marrow was given and the improvement advanced steadily under the use of the marrow after the other agents were withdrawn. The animal product, whether of the yellow or the red variety, is not stated, was given to the extent of three ounces daily. The report ends with the declaration that "The patient is now in a practically normal condition."

Dr. I. N. Danforth, of Chicago, well known as a physician of extensive experience, and as one of the most accomplished microscopists in his city, reported a case of pernicious anemia which, under treatment with arsenic, glycerite of red marrow and various adjuvants, improved so rapidly as to enable him to say at the end of three or four months that the patient "now shows every indication of gradual restoration to health." (*Chicago Clinical Review*, 1894, v.) Unfortunately the evidences of sustained improvement in this case were short lived. Not long after the publication of the report progressive deterioration of health ensued, accompanied by the presence of malarial organisms in the blood, which were now discovered for the first time, and the deterioration advanced to a fatal termination. In view of this unhappy conclusion of an inspiring beginning it would be interesting to know whether the words of assurance used by Fraser two years ago in relation to the status of the case reported by him are equally applicable at the present time. In a personal communication dated April 4, 1895, Professor Danforth informs the writer of his later observations. He considers marrow applicable to all cases of anemia and has used it with temporary advantage in pulmonary phthisis and in Bright's disease; and with apparently marked and permanent benefit in the anemia of rapid growth, overwork and underfeeding. In one case of Hodgkin's disease, in which the remedy was used, the patient got well; and in two cases of splenic leukemia there ensued an increase in the number of red corpuscles and some abatement of the hemorrhagic tendency, without any impression appearing to be made on other phases, or on the

rapidity of progress of the malady. Professor Danforth prefers the red marrow and prescribes it in the form of an aromatic glycerite, of which one dram is given after meals. He directs attention to the possible danger of tubercular and other infections from the administration of uncooked marrow, and recommends the exclusive use of calves' marrow with a view to minimizing this danger.

J. D. Mann reports (*London Lancet*, 1894, I) four cases of anemia, two of them, apparently, cases of chloranemia in girls, and the other two, cases of simple anemia from hemorrhage, all of which were greatly benefited by the remedy; and Chas. Forbes (*British Med. Jour.*, 1894, II) and Henry Hun (*New York Med. Jour.*, 1894, LXI) each records a single observation of like kind.

That the utility of the agent is not limited to simple and easily curable cases of anemia is strongly vouched for by W. G. Bigger (*London Lancet*, 1894, II) who claims to have cured by its influence a case of leucocythemia of six years' standing. Iron and arsenic had been used with benefit on former occasions, but now a time had arrived when these remedies were powerless to prevent active and threatening progress of the disorder. At this time bone marrow was used, and in a remarkably short time it made the patient, a boy, perfectly well. The spleen, previously much enlarged, returned to its normal size. It is to be regretted that the gratifying experience of Dr. Bigger can not, apparently be duplicated by other physicians. That splenic leukemia is not strikingly influenced by bone marrow, as an ordinary event of its use, is clearly shown by the failures of Danforth, already mentioned, and of other observers hereinafter quoted.

One of the most satisfying contributions to our knowledge of the exact powers of the remedy, in various kinds of anemia, is furnished by J. S. Billings, Jr. (*Johns Hopkins Hospital Bulletin*, 1894, v.) This gentleman cites additional proof of its efficacy in chlorosis and chloranemia; and shows that in two cases of pernicious anemia, described with classical minuteness, it proved utterly useless; whereas, arsenic, in these cases, given in increasing doses, proved highly serviceable.

A. McL. Hamilton also records an interesting series of observations. (*New York Med. Jour.*, 1895, LXI.) He tested both yellow and red marrow, but obtained better results from the red. In every case cited the red corpuscles were counted by the Thoma-Zeiss apparatus and their hemoglobin value was estimated by the instruments of Fleischl, Gowers and Henocque. The whites were not counted. Professor Hamilton shows that the multiplication of reds after profuse hemorrhage, is approximately twice as rapid as the maximum rate hitherto recorded (20,000-30,000 daily per cu. mm. of blood), and that the total number of reds can be made to exceed the showing of normal blood (5,000,000 per cu. mm.) by fully 20 per cent. (6,000,000 per cu. mm.) He reports a case of pernicious anemia in which iron, arsenic and cod liver oil had been used without success, and bone marrow had subsequently caused a rapid increase in the number of reds, from 1,000,000 to 6,000,000 per cu. mm. of blood, together with an equally striking improvement in all the symptoms of the disease. The improvement was found to be maintained at the end of two months, but the subsequent history of the case is not recorded. The report includes the results of eighteen

separate studies, most of them relating to cases of ordinary anemia without special features, and demonstrating the value of the remedy.

My own observations concerning the effects of marrow in cases of chlorosis and simple anemia agree in every detail with those already recorded. In one case of splenic leukemia (*Chicago Clinical Review*, January, 1895) the remedy used alone had the effect of increasing the number of red corpuscles and lessening the hemorrhagic tendency without appearing to improve the condition of the patient in other respects or retarding the progress of his sickness to a fatal termination. In this case, also, malarial organisms, so pronounced by two thoroughly trained microscopists, were found in the patient's blood in the last weeks of his life. They had been previously diligently searched for on several occasions without success.

Bone marrow, then, and especially red marrow, is certainly a readily assimilable organic compound of iron and is a valuable addition to the resources of the physician in cases of ordinary chlorosis and anemia, and in some cases of blood impoverishment of a more intractable kind. Whether it is anything more than an assimilable preparation of iron is not conclusively proved. The claims made for it in relation to the cure of pernicious anemia, leukemia and kindred disorders seem to be premature; for sufficient time had not elapsed in any case to warrant such a conclusion. Moreover, in some of these cases, as pointed out by Billings (l. c.), the correctness of the diagnosis is not above suspicion; and, in others, arsenic and iron were given in conjunction, or in alternation with the marrow. We have no knowledge that enables us to understand how it is possible for this substance to effect a cure of pernicious anemia or of leukemia. It can not act like an ordinary animal extract which supplies a deficiency. Its operation must be unlike that of thyroidal extract in myxedema and adrenal extract in Addison's disease. In these disorders there is atrophy or some degree of destruction of the thyroid and adrenals, respectively, and, consequently, insufficient secretion from them to supply the needs of the body; and the administration of an artificial extract of the thyroid or adrenal supplies the demand directly. Whereas, in pernicious anemia and leukemia the bone marrow seems to be hypertrophied and over active, but notwithstanding its activity it is unable to keep pace with the globular destruction that is going on at the same time. Finally, there is no proof that marrow is a secretion. Its function seems to be that of cell production and development. Nor is there any proof that this function is influenced in any way by any constituent or secretion of the marrow itself (Billings). Many accurate observations are needed to make a basis for conclusions that will endure.

ADDISON'S DISEASE AND ADRENAL EXTRACT.

Fourteen cases of Addison's disease are now on record as having been treated with the adrenals of lower animals, mostly those of the sheep. The glycerite of the uncooked, minced organ seems to be the favorite preparation. It is given in quantities representing from 15 grains to 3 drams of the fresh adrenals daily, and these quantities are subdivided into three or more doses. Conclusive proof has not yet been adduced that the preparation possesses curative powers. In about half the recorded cases improve-

ment was noted, and in some of them the improvement was very striking; but information is lacking as to the stability of it.

Fluctuations in the activity of Addison's disease are common, including long periods of arrest of progress, during which more or less recuperation of the digestive and circulatory powers takes place, together with general improvement in the condition of the patient. In a given case it may not be easy to decide whether the arrest and recuperation which are manifest have come spontaneously, or have been produced by force of therapeutic agency.

Quite as good reasons are found in literature for a suspicion that adrenal extract does harm in some cases of Addison's disease, as there are for regarding it as beneficial in others. The whole theory, or fact, of internal secretion in its relations to therapeutics is still of uncertain stability. One can understand how the body, deprived of needed materials normally given to it by process of internal secretion by the suprarenal glands, the thyroid, the kidneys and other organs, may be greatly benefited, when these organs are incapacitated, by the administration of extracts derived from properly selected normal organs of lower animals; but it is difficult to understand how it is possible for such a substitute to eradicate the disease which made its administration necessary. If a patient's adrenals have been destroyed, or permanently crippled, how is it possible for the adrenals of the sheep, given to him a few days or weeks, to make him so very sound and well that ever after he will be able to maintain good health without the assistance of his own?

The only case of Addison's disease that I have treated by this process of substitution was that of a lady of 32, of tuberculous antecedents, who had been ill for four years, sometimes better, sometimes worse. Part of the time there was erratic subfebrile elevation of temperature, but during a much greater part the temperature was normal or a little below. The usual symptoms of the disease were plainly marked—anorexia, nausea, weak digestive powers, constipation, pallor, debility, and enfeeblement of circulation. At times the circulation was alarmingly weak. Bronzing of the skin in various places, face, neck and back of the hands, and a like discoloration of the buccal mucous membrane completed a fairly representative picture. There was no emaciation.

Fluctuations in the activity of the disease were marked and in the early part of its history the lady was able to attend to her ordinary duties a considerable portion of the time without excessive fatigue; but notwithstanding the occurrence of periods of arrest and restoration, relapses of active progress gradually exhausted strength and compelled her to keep to her bed or couch. Under these circumstances bone marrow extract was prescribed, in addition to the arsenic and iron already in use. The patient slowly improved, as she had done several times before without the assistance of marrow extract, under like circumstances of prostration, and hoping to expedite the improvement still more I prescribed a glycerite of sheep's adrenals, beginning with a dose of fifteen minims three times daily, and gradually increasing till dram doses were reached. The larger doses occasioned nausea and were continued only two or three days; thereafter the dose of half a dram was not exceeded. On the third day of this treatment the lady informed me that the new medicine was not

agreeing with her. She patiently continued taking it, however, usually in the dose of half a dram after meals. On the ninth day I noted a temperature of 100.5 (mouth) and on the occasion of my next visit, the twelfth day of the substitutive treatment, the temperature was 102 degrees. Nausea and extreme faintness were now complained of and inability to take the usual amount of food. The lady insisted that the new medicine was killing her, and fully satisfied that the end was near, and that sheep's adrenals could not postpone it, I ceased giving the preparation. Death came quietly, without awaking her nurse, four days later. This fragmentary account teaches nothing except that the *post hoc, propter hoc* philosophy is susceptible of more than one application in relation to the use of animal extracts.

TYPHOID FEVER: ITS TREATMENT BY INTESTINAL ANTISEPSIS AND ELIMINATION.

Among recent contributions to the literature of special therapeutics, few are more striking or suggestive than those of J. Eliot Woodbridge, of Youngstown, Ohio, and W. B. Thistle,¹ of London, England, in relation to the treatment of typhoid fever by sustained processes of intestinal antiseptics and purgation.

These gentlemen appear to have been working independently of one another on the same lines and with substantially the same results, but with different implements.

Their audacious declaration that the disease in question can be aborted every time, if treatment be begun early, and that death from it is never necessary, is likely to impress the average physician as being so extravagant and unwarranted by their own showing as to discourage him from undertaking an attentive examination of the facts upon which the claim is based.

To dismiss the subject with the statement that "the chief merit of the 'Woodbridge treatment' is its harmlessness," as has been done by one of our most distinguished clinicians, who had never given the treatment a trial, seems to me tantamount to prohibiting one from attempting to improve upon present methods of practice. If those who are inclined to condemn the proposed measures without a hearing will turn to any standard treatise on typhoid fever and study the elements of treatment, largely nihilistic, and when not nihilistic, symptomatic, recommended by the author, they will be forced to admit that much improvement is both desirable and possible. The medical profession of this country has been imposed upon so often by shallow and pretentious writers in relation to the phenomenal success they claim to have achieved by inconsequential agencies that now none but persons of recognized eminence are likely to receive prompt and respectful attention. The most successful treatment of typhoid fever in vogue to-day in the great hospitals of the world is undoubtedly the hydropathic, antipyretic method of Brandt; and it is interesting to know that an incidental effect of this treatment is increased renal elimination to the extent of intensifying the toxicity of the urine five fold.² It is also interesting to remember that the free administration of water by the stomach usually has the effect of quieting delirium, depressing temperature and making notable improvement in the general condition of

the patient. If elimination of the products of bacterial activity is to be recognized as an important object and effect of treatment what is to be said against the proposition to destroy or restrain the activity of the bacteria themselves and thus prevent the elaboration and absorption of their toxic products? It is this that Woodbridge and Thistle claim to do and urge their professional brethren to do.

It is unfortunate that the basis of therapeutic effort maintained by the gentlemen referred to, is so much obscured by the prominence of fantastic details; for, if attention were limited to the underlying principles the reason of the reader would be less grievously offended.

In justice to our colleague from Ohio it must be kept in mind, however, that he has vigorously and repeatedly disclaimed any intention to foist upon his professional brethren *sine qua non* specific compounds to be given unfailingly in one, two, three, or four, for the infallible cure of typhoid fever. His prescriptions are merely intended to serve as a guide to the application of principles. Thistle does not use the same medicines at all and yet his results, so far as they go, are no less satisfactory.

The especial merit of the plan of treatment under consideration, if it have any, does not reside in any new conception that is embodied in it, for there is none. It resides in the promptitude and vigor with which long-recognized but heretofore feebly administered therapeutic axioms are put into play. It will not be claimed, I think, that there is any specific merit in podophyllin or that it is strictly necessary to require a patient to swallow a particular tablet every fifteen minutes for thirty-six hours before permitting him to take a dose of epsom salts. The vital requirement is to disinfect the bowel as quickly as possible and at the same time to establish and maintain free drainage or elimination. It is a fact of easy demonstration that if this be done early, meteorism will not occur and the discharges will be without unpleasant odor. More, it can be easily demonstrated that meteorism already present, is dispelled by this treatment and that the fetor of discharges is gradually corrected. Putrefactive processes in the bowel contribute something to the natural history of typhoid fever. Every case of the disease is an example of mixed toxemia and the chief primary seat of infection is the intestinal mucous membrane.

The attitude of incredulity and indifference that is generally maintained in relation to the claims of Woodbridge and Thistle seems to be justified by the well-established fact that the bacilli of typhoid and the toxins they produce are not limited to the lumen of the bowel but have penetrated into the walls of the tube and, to some extent, found their way to remote parts of the body before the physician is ever called upon to give a dose of medicine; and it may well be doubted that any process of local treatment of the alimentary canal can make an important impression on the life history of the microorganisms which are now distant from it. It must be remembered, however, that before the bacilli can invade the tissues they must be present in the lumen of the bowel. It must be remembered that they multiply here. It must be remembered that the process of invasion of tissue and transmission to remote parts is not completed in a day but is a continuous and progressive one, lasting many days. It must be remembered that the effect of these organisms on the invaded tissues of the bowel—

¹ Canadian Practitioner, April, 1893; Medical Record, March, 1894, and Sept. 14, 1895.

² A. H. Burr, Chicago Medical Record, October, 1894.

inflammatory swelling, necrosis, etc.—depends on the number present at one time, the duration of their stay and the degree of concentration of their toxins. (Thistle, Sims Woodhead.) It must be remembered that the severity of an infectious disease, and the liability to intercurrent infections, depends, other things being equal, on the degree of the concentration of the toxic principles in the blood. If these facts are kept in mind it will appear rationally possible that by processes of purgation and antiseptics we may be able to prevent, in some degree at least, a concentrated infection of the lymphatic structures of the bowel and the consequent destruction of them, together with concentrated systemic infection and its attendant dangers. It is also rationally conceivable that the duration of the disease may be shortened.

The bacilli that have already reached remote parts of the body doubtless play an important role in the evolution of the natural history of typhoid fever; but it is plain that if the number be kept within bounds by restraining the activity of recruiting from the bowel, the minimum amount of damage will be done and the best possible opportunity will be left to invaded parts to destroy and triumph over the limited number of bacilli which have reached them.

If the foregoing course of reasoning is correct it points to the conclusion that the earlier antiseptic and eliminative treatment is instituted and the more thoroughly it is maintained, the more effective it will be. To withhold its employment a week or two, and permit the intestinal structures to become saturated with microbes and toxins and the system at large to become overwhelmed by concentrated infections would not be giving either the treatment or the patient a fair show. Processes of prevention are not to be expected to cure damage that has already been done.

It is not desirable that the antiseptics be absorbed. It is sufficient if a continuous stream of them be kept passing through the alimentary canal. To give them and allow the bowels to remain constipated is to invite the absorption of toxins that have already been elaborated. By making the culture medium noxious to the germs, by the use of antiseptics or germicides, and at the same time by diluting this medium more and more by the action of purgative medicines all will be done that can be done by these therapeutic measures. Continuous purgation is, I conceive, of at least equal importance with the continuous use of intestinal antiseptics.

One fact appears to have been fairly demonstrated by Woodbridge and his followers, viz.: That purgation begun early in the clinical history of the disease and continued steadily throughout its course does not increase liability to perforation or hemorrhage. It seems to lessen it. This can hardly be considered as soundly established, for the examples of typhoid fever that have appeared during the last two or three years have been, for the most part, uncommonly mild; but if it were soundly established it would not warrant the conclusion that active purgatives previously withheld can be administered without danger when grave intestinal lesions exist.

Permit me to direct attention to the rapidly growing statistics upon which the claims of Woodbridge are based. To say nothing of the hundreds of cases reported by himself in which little or no bronchitis occurred, little or no delirium, little or no subsultus, little or no meteorism, little or no dryness of the tongue, but little circulatory and thermic disturbance and no

perforation—cases that pursued a singularly brief and benign course; that were free from complications of every kind and invariably terminated in recovery when treatment had been begun early; let us consider the testimony presented by other writers:

Thistle (*loc. cit.*) has reported one hundred and seventy-two cases representing all grades of severity and progress when treatment was begun, with a mortality rate of 3 per cent.

F. Grover (*Jour. A. M. A.*, Feb. 15, 1895) reports fifteen consecutive recoveries; E. J. McCollum (*IBID.* Feb. 1, 1896) reports eighteen and J. J. Orton, eight; Wesley Davis (*IBID.* March 4, 1896) reports eighteen; W. B. Shields (*IBID.* April 11, 1896) reports twenty-eight recoveries and one death; and the present writer now reports twenty-one consecutive recoveries covering his private practice of the last two years. Total 275 cases and 6 deaths—a mortality rate of 2.2 per cent.

Considering that these cases came under treatment at various stages of progress of the disease it would appear probable that there is something of merit in the plan; and yet we are not to forget that during the past two or three years it has been uncommon for typhoid fever to terminate fatally under any kind of management and that exalted enthusiasm in relation to a particular specific method is far from having a safe foundation.

Hemorrhage occurred in two of Shield's cases and in one of them, it caused death.

In Davis's series four examples of hemorrhage and two of relapse are noted.

The cases referred to by the present writer included various degrees of severity and advancement when treatment was begun.

It is not claimed that the "Woodbridge treatment" was employed in one of them. Neither the trivial differences between prescription "No. 1" and prescription "No. 2," nor indeed, the prescriptions themselves, have impressed the writer as being of vital importance to any of his patients. The plan of treatment followed consisted, in a general way, of purgation—to the extent of from three to six evacuations daily, begun at once and continued throughout the course of the affection—together with intestinal antiseptics. The purgatives employed were of various kinds but usually either mercurial or saline. The antiseptic used was generally the mixture of guaiacal carbonate gr. iij, thymol gr. i, menthol gr. ss, and eucalyptol m. i, referred to by Woodbridge as "Prescription No. 3;" and it was given in the form of a capsule every two or three hours.

Other measures of treatment were not ignored. Rest in bed was enjoined in all cases, and the diet was of the kind in vogue with the profession. Sponging was used in all cases with more or less frequency and in one, that of a medical student, the Brandt treatment was employed systematically for a period of ten to twelve days. In short no attempt was made beyond that of studying the effect of continuous purgation and antiseptics in typhoid fever—and that without neglecting the use of better established methods and measures.

Although no death occurred the results, especially in the direction of aborting the malady, albeit not discouraging to one who had not expected much, were much less brilliant than those recorded by our friend from Ohio.

Limiting attention to thirteen cases in which treat-

ment was begun during the first week, even upon the uncertain basis for diagnosis that was generally found at the time. I respectfully report that two of these cases proved to be of the abortive variety—one reaching normal temperature on the ninth day and the other on the fourteenth.

In one case, that of a physician, a single relapse occurred; total duration thirty-eight days.

In another, that of a student, a second relapse occurred, total duration sixty-four days. The first relapse was engrafted on the primary attack and was indicated by the occurrence of epistaxis, abrupt rise in temperature and pulse rate and the appearance five days later of a rather coarse, but sparse, roseolous rash. A similar train of phenomena appeared during the seventh week. The primary course of fever was of moderate severity but the first relapse was uncommonly violent. Pneumococci were abundant in the sputa but no pulmonary consolidation was discovered. During the second relapse several small abscesses appeared, subcutaneous and submucous (buccal).

The remaining nine cases were singularly mild and free from bronchitis, meteorism, offensive discharges, dryness of the mouth, apathy, delirium, subsultus, hemorrhage and other disturbing manifestations. The usual pulse rate was between eighty-four and one hundred, and in no case did it go beyond one hundred and four. After the third day of treatment in no case did the temperature go above 102.5 degrees. The average duration of the nine cases was seventeen days.

It is not assumed that this inconsequential showing proves anything. It is merely in line with the ordinary observation of medical men in respect to the mildness and benignancy of typhoid fever during the past two or three years. Nevertheless there is enough merit in the conception of intestinal antiseptics and drainage, as a means of obviating continuous intoxication, to warrant one in giving it free and fair play. No one has a right to condemn it without proof.

ORIGINAL ARTICLES.

CAN WE IMPROVE UPON THE SANITARY CONDITION OF OUR CARS?

Read at the Second Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Ill., Sept. 25-27, 1895.

BY WM. T. DALBY, M.D.

ASSISTANT SURGEON UNION PACIFIC RAILWAY,
SALT LAKE CITY, UTAH.

I take it that every physician is a sanitarian; if not, he should be. The doctor's true sphere of action is not confined to disease alone, but embraces man's whole life when in a state of health as well as when in a state of disease.

A knowledge of the laws of hygiene is essentially necessary to the education of every physician, and its worth as a true science is of no less importance to the general public. We find in searching the archives of the past that those who preceded us in our noble calling recognized the science of sanitation as a true sister to the art of medicine as well as her greatest, brightest ally. Every civilized government has assumed the inherent right to protect the health and provide for the safety and welfare of its people; and this is not merely a presumed right, but it is a duty and obligation which the sovereign power owes to the public. That this is true and that sanitation has

been from the remotest period of history an integral part of medicine and accorded a place of distinction in the councils of ancient governments can not be denied. Let us for a moment, as a prelude to this paper, look into the realms of now almost forgotten history with reference to the laws governing public health.

This department of science (sanitation) has received so strong an impulse during the past few decades that many persons regard it as of modern origin; but on turning back to the records of early history we almost invariably find evidence that the health of the general population was a subject of legislation.

The Mosaic code of laws, the most ancient on record, contained minute directions for cleanliness of the person, the purification of the dwellings and the camp, the selection of healthy and the avoidance of unhealthy food, the seclusion of persons with contagious disorders and various other points bearing on the physical well-being of the Jewish nation.

The Greeks and Romans—although not like the Jews, making hygiene a part of their religion—were far from neglecting it. The laws of Lycurgus, says Dr. Gairdner, "are not wanting in very pointed enactments on sanitary matters; and the importance attached by the Greek Republic, and in the Platonic polity, to physical culture is too well known to require remark."

"The Roman people, poor and apparently rude as it was in its origin, yet found time, amidst its military operations, to construct the *cloaca maxima*, an indestructible and stupendous memorial of its attention to the drainage and sewerage of the city at a very early period of its history. At a later period aqueducts were made to cover miles upon miles of the surrounding plain; and their splendid ruins, still partly used for their original purpose, attest the munificence and the abundance with which the first of sanitary requisites was supplied to the imperial city." When state physicians were first appointed in the Roman Empire is not certainly known. Their mode of election is described in the Theodosian and Justinian codes. There were ten of them in the largest towns and to each district or subdivision, seven in towns of the second order and five in smaller ones. They collectively formed a college whose duty it was to attend to public health, and they may be regarded as the earliest type of our general medical council.

We find on our own continent that the ancient and energetic Aztecs were not ignorant of the laws of sanitation; and long before the sailing of Columbus from Palos, we find that their water supply and efforts at drainage evidence their knowledge and appreciation of hygiene equal to if not superior to that in vogue in some of our municipal governments of to-day.

Gradually, however, as Christianity spread, an utter misconception of doctrine led to the neglect of all care of the human body, and the question of public health, the foundation of a nation's wealth, growth and happiness, was ignobly buried in the darkness of the middle ages. It has now been unearthed by the inexorable demands of modern enlightenment, and gaining ascendancy, has greatedened and glorified medicine without marring the luster of her scientific consort, and to-day she turns to the people and their rulers, outside the medical fold, and demands as her right a place of honor in their councils. Thus we see

that from time immemorial it has been as much the physician's duty to regard the laws of sanitation as to treat the ills arising and sure to follow a violation of her mandates.

When we find that the air of passenger cars is shown upon careful examination to be equal in impurities, greater in amount of carbonic acid than some of the sewers of our cities, and the sleeping car to be pronounced a "hot bed of infection," it is time for us as railway surgeons on behalf of our respective railway companies and our duty to the traveling multitudes to investigate and see whether or not we "can improve the sanitary condition of our cars."

Permit to quote from a recent edition of the "National Board of Health Magazine."

"Everybody knows that the aim of the car-builder of the present day is to make the sleeper a palace on wheels. The seats are upholstered with the softest material, combined with reasonable durability; the carpets are most velvety; the curtains soft and rich; the mattresses, pillows, blankets and coverlets of the best. The whole furnishing of the car is similar to a private drawing-room."

Who could ask for more in the sense of comfort? And what is here said of the sleeping car, can be with equal propriety and justice claimed for the passenger car. We know that the passenger car of to-day is the evolution and product of many years of careful study, and it would appear that in meeting the demands of the traveling public it has nearly reached the limit of perfection in dimension and compactness as a component part of the train. In many instances from the artisan's point of view it is constructed both as elaborately and comfortably as the handiwork of the mechanic can devise. In the life and competition for trade, the rapidity and comfort in transit has stimulated our various railway companies to build and improve the passenger car so rapidly that we look with admiration at the results achieved in all that is artistic and beautiful in veritable palaces on wheels, speeding over mighty domain as true evidences of the skill and enterprise of our progressive people. With all this, however, we must admit that the sanitary condition and arrangement of the passenger car is bad, and this condition is often made worse through neglect or ignorance in the use of those means at hand provided for its ventilation and cleanliness. There is no doubt that had the mechanic gone hand in hand with the sanitarian in the construction of the passenger car, greater results would have been achieved. Certainly, so far as lighting, heating and ventilation is concerned, measures have been so far neglected as to call for legislative enactments in many instances, and a world of literature looking to the correction and improvement of the existing evil.

We quote further from this article by Dr. Pattison, on "Car Sanitation." After describing the various physical conditions of those who travel in the sleeper, and noting the infectious nature of tuberculosis he says: "And the tuberculous patients travel more than any other classes in search of suitable climate. Persons suffering from phthisis pulmonalis are to be met with in the sleepers upon nearly every transcontinental train. They cough and expectorate as all such do, sometimes in the cuspidor, sometimes in the handkerchief, but very frequently on the carpet as this is not their own. When on the last, the germ-laden expectoration becomes rapidly dried and ground with dust, rises in the air of the car and is inhaled by the sus-

ceptible fellow passenger, often an innocent stranger. It is quite rational to presume that in this way the fatal disease is often spread."

The doctor then goes on to say: "What, after a time is the sanitary condition of the sleeper? It becomes simply a hot bed of infection. It can not be otherwise, for no efficient measures are taken to prevent it. The sheets and pillow cases are changed daily, sent to the laundry. Allow that they are thus purified; what is done with the mattresses, pillows, blankets, coverlets, and curtains? They are closed up from sunlight and air in the upper berth, and for months at a time they are never exposed to nature's purifiers."

"So far as the car itself is concerned, at the end of the trip, the carpet is swept, the cushions brushed in a dry condition; a profusion of germ-laden dust rises to settle again; what falls upon the wood work, and is visible, is brushed off with a duster to settle again on the carpets and cushions, where all remains in the most favorable condition to be raised into the air by the next set of passengers and the motion of the car upon the return trip. To my mind, the sleeper of to-day is an extremely active factor in the propagation of infectious diseases, more so on account of its luxurious furnishings than other cars."

It can not be said that these remarks are overdrawn or exaggerated, neither will anyone doubt the infectiousness and contagiousness of tuberculosis nor the vast numbers who are constantly traveling afflicted with this disease in search of genial climes to invigorate their exhausted frames. What an infectious field the car from such contamination becomes in spreading disease among the innocent and unprotected public. And tuberculosis is not alone in the consideration of this unwholesome state of affairs, for the germs of many other infectious diseases are lodged and housed up through this want of better hygienic measures to wreak vengeance upon the unsuspecting.

Many suggestions have been made with reference to abating this evil, including many alterations in the construction of the car, the abolishing of the draperies and tacked-down carpets and other furnishings that will not withstand the proper methods that should be used in a thorough fumigation and disinfection.

Restrictions are likewise suggested to be imposed upon invalids requiring them to have certificates from the proper authorities showing freedom from infection as is necessary in the transportation of the dead. Many of the suggestions are practicable and could be easily put into operation, and carried out with little expense.

It is questionable, however, if under our form of government, State or federal, invalids could be obliged to present a certificate showing freedom from infection before being permitted to obtain transportation as it is required in transporting the dead.

It is certainly true, that it is as dangerous and hazardous to the public to carry by rail the infectious living as it is to carry the infectious dead, and probably more so, since the carrying of the dead will never equal in number the invalid class nor are the conditions of possible contact the same: to have in the same car persons afflicted with infectious diseases disseminating and spreading germs under the most favorable conditions is much more dangerous to the public than are the infected dead in the baggage car.

Still, the law of equity would grant privileges to the one that the relatives of the other could scarcely exact

as an inherent right. We can not prevent the infected from traveling no matter how plainly we may demonstrate the death dealing germs left in their wake. We must exert sanitary measures and precautions and depend on these to protect the public from disease.

If we wish to improve the sanitary condition of our cars we must not only look into the questions of ventilation, heating and lighting, but we must go beyond this and show to the car builder the wisdom of consulting and associating with the mechanic the ideas of the sanitarian. It is difficult and, in many instances, quite expensive to improve upon a poorly constructed car from a sanitary standpoint, and to attempt such improvement would necessitate an outlay greater than many of the companies would be able to bear. To accomplish the most good by having a properly ventilated car, and one that is susceptible of the greatest cleanliness, we must direct our attention to the building of the same. It is said that the most intelligent men of our country are engaged in the management of railways, and the fact that so little has been done in the way of railway sanitation is simply because these gentlemen are unaware of the value of such a departure, and have not been made to see the monetary gain that would accrue to their several companies by the proper enforcement of sanitary laws. This is undoubtedly true; so, also, is it true, that in a great organization of railway surgeons as we have here, the importance of sanitary measures with reference to the hygienic condition of the coaches should be studied, and the knowledge thus derived should be given to our respective railway companies for their information and guidance. I do not think that we should so long ignore these matters of vital importance as to let the legislative branches of our government step in by their enactments and describe, for instance, the manner in which heat should be applied to the train, any more than we should wait and expect from this same source information and instruction regarding the treatment of fractures and other injuries resulting from wrecks. I trust that it will be the sense of this association to deem it a duty incumbent upon it and always to look into the sanitary condition of our cars with a hope of improving it.

I do not intend to attempt in this paper to suggest to you what would be the most improved ideas of car sanitation. This must be reserved for the more efficient sanitary engineer, whose scope and field of observation is far greater than mine.

To this same expert must be left the plan of ventilation, complex and difficult of solution as it is, the maintenance of proper temperature and the best system of water-closets. All of these are susceptible of vast improvement.

The question of cleanliness, however, in the car proper, the water coolers, the purity of the ice and water supplies are matters that we are capable of coping with. If it is carried out by some regulated system of rules enforced by all the railway companies alike, a more wholesome and healthful condition will result to the public and we will be credited with the honor of having improved the sanitary condition of our cars.

All coaches, day or sleeping, especially after long trips, should be subjected to a cleansing and disinfection. This can be done in several ways and should be provided for in the necessary instructions given the employes having this matter in charge. The

same rigid rule should apply also the bed, bedding, carpets and draperies of the sleeping car. Not only should the car be cleaned at the end of each trip, but as far as possible it should be kept so while in transit. Since many people of filthy habit travel, the necessity of this will become obvious. The water coolers, which are scarcely if ever washed, should receive closer attention; likewise the ice and water with which they are filled, and the often disgusting manner in which this is done. The cuspidors should be cleaned as often as necessary, and when used by the tuberculous, should be disinfected; and until a better system of closets are devised, dry earth or a freer and more elaborate system of flushing should be provided.

Whatever system is adopted looking to a better sanitary condition of the cars should be one that is enforced by all the roads alike.

In concluding this paper, I thank you for your kind consideration and hope that I have been successful in showing why we as railway surgeons should be sanitarians, and why some of our deliberations should be in the direction of the improvement of the sanitary condition of our cars.

DISCUSSION.

DR. REED, of Columbus, Ohio—I believe I have been generally known as a sanitary crank, and I presume that for an individual who has as little money as I have to spend in this matter, I have spent perhaps as much as any man in the country in investigating the matters about which the author of the paper has written. I made a sanitary inspection of the Big Four, the Panhandle, Pittsburg, Fort Wayne and Chicago and the Baltimore and Ohio Railroads some years ago. This inspection consisted in the investigation of the air by chemic analysis, the investigation of the cars, the plan of heating, the water-closets and the ventilation; the temperature of the car at the floor, at the level of the mouth and at the ceiling, and it required no small amount of time, work and expense. After examining this matter carefully I found a great many things to recommend in my report. I had the pleasure of sending a copy of this report to President Pullman, and received a reply from him stating that he believed my suggestions were good. The trouble usually arises with the superintendents and the managers, who are, so to speak, between the devil and the deep sea. They are anxious to make the cars as comfortable and as handsome as possible to accommodate the traveling public, and on the other hand they must curtail expenses in order to maintain their positions as servants of the stockholders. To add these improvements means expense, and so long as the traveling public does not make any special claim for improvements on the cars, they do not feel inclined to make them. I do not think there is a general manager who would not admit that the paper read by our friend here was right and every word perhaps in it true, but they look at it from a business standpoint only. Quite a number of general managers have expressed their opinion to me on the subject and have said there was no question about its importance, but that so long as they were not required to make these improvements in order to get passenger traffic over their roads they did not deem it necessary to take the lead in the matter. I have no doubt Mr. Pullman looks at it in the same light. He sees very plainly that an elegantly fitted car, when placed beside another on the track that is not so elegantly fitted up, at the same price and going to the same place and making the same time, will be preferred by the public. I believe that until the public is educated in the matter you can not get the railway companies to adopt a new plan until the riding public demand it, and say to the railroad managers, "We won't ride on your road unless you give us a sanitary car to

ride in." I think the time will come when we will have these improvements, because I am sure the companies will be ready to make the expenditures if they see a return for this extra expense, but they do not feel like making the expenditures otherwise. Railroad companies are not organized for philanthropic purposes; they are organized strictly on business principles, and unless this can be demonstrated as a business enterprise, I do not believe it is possible for us to reach improvements.

DR. BEVAN—I believe that the paper of Dr. Dalby touches a very important kind of work, and the question has occurred to my mind whether or not it would not be possible for this Academy to bring out results of some practical value in this line. Whether it would not be possible for us to very thoroughly, as an Academy, investigate this whole subject and formulate some practical rules which we, as the Academy of Railway Surgeons, could recommend to railway companies, even to State legislatures, or the Interstate Commerce Commission. It certainly is a very valuable line of work, and it must be carefully worked out by just such men as the members of this association. With this in view—this is merely a suggestion—I should think at our next annual meeting it would be well to have several papers covering this entire ground, not only in a general way, as Dr. Dalby has done, but in a specific way, with specific and practical recommendations to the Academy.

DR. JOHN E. OWENS, of Chicago—I have for a long time felt that something in the direction of this paper should be done. In taking a long ride of 800 or 1,000 miles I have now and then watched the different varieties of the genus homo that refreshed himself or herself at the drinking fountain or water cooler, some evidently with pulmonary disease, tuberculosis, etc., and in a sleeping car, unless I am sleeping. I believe as the matter of tuberculosis is getting so well understood, slowly, it is true, by the public, and also in consequence of the existence of such papers as has been given us by Dr. Dalby, that the public, and consequently the railroad companies, will feel the evolution in the right direction and eventually we will have some attempt in the way of the construction of a car which will meet the objections presented by some of the luxurious cars in which we now ride. It will be a matter of very slow progress. I take it that some enterprising company will build one sanitary car and run that for a time; perhaps some other company as an advertisement will set forth to the public that the Sanitary Car will leave Chicago for Denver at 8:40, with no possible danger of any contagion or infection. It will come about in some such way, but the doctor can not do it unless he has the coöperation of the railroad authorities, as has been suggested, and with them the sanitarians of the country. The public health associations and all the representative bodies of this character in the country will in time, I presume, coöperate and their united effort will bring about the desired results. Certainly all the conditions for the spread of such contagion must be present in both the day coach and the sleeping car, as has been set forth by Dr. Dalby in his paper. The public, as has already been stated, comes very slowly to a realizing sense of what they should do to protect themselves. They don't appreciate what is done by others; we see that in the hospitals. It is useless to give a consumptive in a car a spit-cup to use and to throw out of the window. The carpet that he does not own, and the floor will be used in preference to these, however accessible they may be. I have not anything to recommend.

DR. MAYNARD—Following the paper of Dr. Dalby and following the line of Dr. Owens, I have noted for a great many years the unsanitary condition of cars, as a rule. All well-to-do consumptives travel by sleeping cars. It is through the agency of such an organization as this that we can do some good in a sanitary way. I happen to have a very close personal acquaintance, extending over a great many years, with the Pullman Company, the leading sleeping car company in the United

States, and I know that Mr. T. H. Wickes, the vice-president and general manager, and Mr. Gusten, the general superintendent, are anxious to do all they can, not only to make the traveling public comfortable, but to make their cars sanitary. I know this fact from conversation with Mr. Gusten to-day that they will be very glad to do anything they possibly can in order to make their cars sanitary, and would, I believe, take the lead in any movement that might have the endorsement of such an organization as we are, and consider any well-formulated and well-digested plan that might be presented to them. As to railways generally, they are like the rest of us, after the dollar, and as long as the suffering public are not educated and will put up with it, they will give just such accommodations as will keep up their passenger receipts. But any well-defined and well-formulated suggestions from an association of this kind would receive, from the Pullman Company at least, not only a courteous reception, but would be met more than half way. I know the danger. I see the consumptives on the road, hear the cough, see the spit, and as a rule I ride on the baggage car to save myself. But I believe it would be well for us to formulate, in the line of Dr. Dalby's paper, a set plan and submit the same, not only to the sleeping car companies, but to all passenger carrying roads.

DR. W. J. GALBRAITH, of Omaha, Neb.—I fully appreciate Dr. Dalby's ability to write upon sanitation as well as his ability in the profession in general. While it may be humane and it may be sympathetic for us to look upon this matter in the way we have, I do not deem it in the province of this association to make recommendations that we are not called upon to make by our general managers. It would be just as absurd for us to make recommendations how a locomotive should be made, how a road-bed should be graded, etc., as to enter into something that has no connection whatever with our positions. We are employed as surgeons and physicians to railroads to care for the sick and injured employees and those for whom the railroads are responsible. It is the duty of the master car builder and his associates and the chief engineer to put into practical execution all these measures that we are discussing, and they are constantly working upon sanitation, as well as the general improvement of their rolling stock. They are men who are educated and men whom our general managers depend upon to make such sanitary conditions, as well as safety conditions to transport their passengers. We have had in associations heretofore papers that have done railroad surgeons' associations a great deal of harm. I believe that the recommendations of Dr. Conn as contained in his paper have done more injury to the railroad surgeons and their societies than all other actions that have taken place during our short existence. We speak from a sympathetic and humane standpoint, which is all right. I appreciate that. I think it is all right for those things to be considered. At every discussion pertaining to the sanitation of cars, the first object has been tuberculosis. It is not directed to the public in general where the families intermingle and sleep together, in hospitals, where you have a tuberculous patient and one suffering from a different disease right next to him. Those things are not taken into consideration. We are not making recommendations in the proper channel. I believe that the paper by Dr. Dalby is a very valuable one; it shows good judgment and good sense, but if it is printed and the transactions sent to our general managers for review, we will be doing a great deal more harm than we will be doing good. It is something that we are not called upon to perform and it is not our duty to make those recommendations. Now the hospital care for the transportation of patients. This is a matter we have discussed in associations heretofore, and I have had it repeatedly from two or three different sources and from general managers, how absurd it would be for every trunk line to furnish cars for the transportation of tubercular patients. It is entirely out of the question that a trunk line

can afford to equip cars to start from Chicago to the Coast, to have a special car arranged for the transportations of tubercular cases. It is just as absurd as it is for the accident cars we have made recommendations for in associations I have been connected with. We have recommended that automatic couplers be immediately placed on all roads. What business have we to make such recommendations? None whatever. That is not our province whatever. I have fought the automatic coupler, I have fought the tubercular cars and the accident cars from the time our organizations of railroad societies started, and I hope this will be the last fight I shall have to make.

SANITARY REGULATIONS GOVERNING RAILWAYS.

Read at the Second Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Ill., Sept. 25-27, 1895.

BY L. E. LEMEN, M.D.

DIVISION SURGEON, U. P. RY., DENVER, COLO.

It is not often that a railroad surgeon is called upon to speak before you upon matters pertaining to public health. Yet, in this particular, we are not to judge the future by the past. This is truly the era of preventive medicine, because we find not only all branches of medicine battling against every scourge, but the public in general has its thoughts set on the laws which are apt to conduce to good health. It would seem that, at last, the laity has commenced to appreciate the meaning of the old adage: "Public Health is Public Wealth."

In the revolution that is now taking place in scientific and social circles to promote the health of the people it behooves the railway surgeons, and railway officials to pause for a moment as to their duties and capabilities. To remain inactive in matters of this kind will be considered criminal and costly, and instead of deferring the necessary preventive measures in certain diseases until the railroads are compelled by State and National statutes to observe laws more or less stringent and often impracticable, it would appear to be the part of wisdom, first in the railway surgeon to pay special attention to State and municipal hygiene and the laws of the different localities governing the same, and second for the railway managers themselves to instruct their agents to supervise and direct as much as possible the sanitary legislation referring to public carriers.

In all the concerted effort for the public welfare now taking place we find State medicine especially concerned in restricting the spread of tuberculosis in general, and tuberculosis of the lungs or pulmonary consumption, in particular. It is on the subject of the latter that I propose to speak more especially as a railroad surgeon.

The value of Koch's discovery in fixing the specific cause of phthisis to the invasion of the tubercle bacillus is magnified day by day as we contemplate the possibilities of State medicine toward stamping out disease.

That pulmonary phthisis is a communicable disease no one will to-day question. The mode of spread is various, such for instance as: 1, taking the germ of the disease into the system by drinking infected milk; 2, the ingestion of diseased meat; 3, from the expired breath; 4, accidental contact with the expectoration and the discharge from tuberculous sores; 5, inhalation of air laden with bacilli from dried tubercular sputa.

Of the methods by which the disease is communicated, the latter, namely, the inhalation of air laden with bacilli from dried tubercular sputa, is recognized

to be the most common. It is in this mode of infection that the railroad surgeon is principally interested, since overcrowding in cars, poor ventilation and faulty construction specially favor the spread of the disease.

We have every reason to believe in the potency of isolation for the restriction of the spread of tubercular disease, and we read the signs of the times from those boarding houses and hotels who now advertise for non-tubercular patronage at the same time that sanitarians are advocating the value of segregation of consumptives into properly built cottages away from populous centers.

Facts such as these offer suggestions of value to railroad officials. If it is manifestly dangerous to receive the tubercular subjects in hotels and boarding houses occupied by people generally what should be the rule to be observed in railroad travel in a country like ours where people have such a tendency to move about? Take for instance railroads leading to resorts for consumptives where a great percentage of the travel is done, especially at certain seasons of the year, by the infected class, and then figure on the ill effects of permitting the sick and the well to travel together.

The time has arrived when the railroad sanitarian must point out these dangers. As scientific men we do a great deal for the cause of preventive medicine. I believe it is important that we should recommend the following.

1. Segregation of the consumptives in railroad travel.
2. The compartments of the infected individuals should be constructed in such a way that disinfection and cleansing may be easily accomplished.
3. The sleeping cars should be provided with drapery easily laundered, and all drapery should be washed as often as once a month.
4. The bedding of the isolated compartments should not be interchangeable with that of the other part of the car, and articles like blankets and mattresses should be steamed at least once per month.
5. The dangers of spreading the disease through the medium of dried sputa should be stated in circulars conveniently posted in the isolated compartment, and the necessity of expectorating into spittoons and not on the floor or in handkerchiefs should be specially dwelt upon.

DISCUSSION.

DR. C. M. DANIELS—In the new instruction book I am issuing to the physicians and employes of the road I represent, I have added a clause directing surgeons, when traveling over the line, to make an inspection of the train and in case any unsanitary conditions are found, that attention be immediately called to the same and reported promptly to the chief surgeon.

REPORT OF FIVE CASES OF TYPHOID FEVER TREATED BY THE WOODBRIDGE METHOD.

BY H. SCHOENFELD, M.D.

TRENTON, OHIO.

Case 1.—Lena F., of Trenton, Ohio, age 21 years; single; a domestic; began ailing on April 16 with the characteristic symptoms of typhoid fever. Had been working in family where two long prolonged cases lay. Saw her on April 30 and put her on iron, quinin and strychnin pills; aconite and digitalis and used turpentine stupes. Pulse 120, temperature 102.2. Third day temperature was up to 103. Put her on Woodbridge tablets No. 1 every hour. Fourth day gave them every half hour. On fifth day put her on No. 3 in a liquid form which after a while caused vomiting, which finally became very bad; so I ceased its use, her chief complaint being in the

epigastrium. Kept her on No. 1 and used papoid, listerin with aconite, digitalis, etc. Normal temperature was present on the evening of the twenty-third day.

I did not understand treatment as it was my first experience with it. There occurred no hemorrhage, and the only complication was gastric trouble and hysteria.

Case 2.—Harry K., of Miltonville, Ohio, American, age 27 years; married; a farmer. Had been complaining for two weeks. We thought he had dumb ague. Nose bleed occurred on July 31. August 1 the tongue was thoroughly coated, felt tired and aching; rigors more or less all day: very tympanitic and sensitive. Pulse 78, temperature 102.4. Gave tablets No. 1 every hour for first twenty-four hours. Second day I gave them every half hour (when I got five evacuations from bowels), until evening of third day, when I put him on No. 3 in addition, in fluid form. Fourth day, noticed the breath to be offensive, some sensitiveness in mouth and gums, so took him off of No. 1 and used pot. chlor. during that day. I continued No. 3, but put him back on No. 1 again on fifth day and continued thus. Normal temperature on morning of fourteenth day and same next evening.

Up to this time I did not do my patients or myself justice, owing to the fact that I had these formulæ put up by my local druggist and had some trouble in their use. I procured medicines from Messrs. Parke, Davis & Co. for my next case and continue to use them.

Case 3.—Valandingham F., of Busenbarks, Ohio, American, age 24 years; single; imbecile; a farm hand. Symptoms of typhoid fever first showed August 31, but he lagged along till September 4, when I first saw him. The bowel lesion was very pronounced and sensitive. Pulse 80, temperature 102, A.M. Not having Woodbridge tablets with me I put him on iron, quinin and strichnin pills, with listerin, aconite and digitalis. Next day, after a very restless night, put him on No. 1 every fifteen minutes, and applied turpentine stupes. Continued the same treatment during the next day. On the fourth day added Nos. 2 and 3. Kept this up regularly, varying the treatment only with the action of the bowels, and he had a pulse of 69, and temperature of 98.6 on the morning of the ninth day and evening of the following day.

The patient was fairly strong and I discharged him with the strictest admonition to be a little careful of his diet, as he had been extremely sore. So things progressed well for fourteen days, during which time he was up and out, moving around and feeling fine. The whole family being of a low grade of intelligence, what this poor fellow did not think of and call for to eat, they reminded him of; among other things fresh pork just butchered. As he was somewhat of a glutton he stuffed himself, and on the evening of the fifteenth day of freedom, twenty-six days after the beginning of the sickness, he was taken with a heavy chill. Next morning at daylight I was hurriedly summoned and just before my arrival I found he had had a stool of pure blood; I think about two or three pints. The pulse was 96, temperature 103, considerable nausea, and the appearance of the vomit like a lump of pure putty, well greased. My prognosis was not favorable. I put him on the orthodox treatment to arrest hemorrhage and to sustain the heart's action and strength and gave No. 3 capsules as required. With six more hemorrhages and a considerably lower temperature he passed to the fourteenth day, when the temperature touched normal and remained so, and he lives to-day turning the scales at over 200 pounds.

Case 4.—Bertha S., Middletown, Ohio, American, age 20 years; single; a housemaid. I was called hurriedly by telephone on the morning of December 28 to Middletown, to see this patient who had been treated for ten or twelve days by a medical friend. He had diagnosed and was treating typhoid fever, which diagnosis I confirmed. I found a very sensitive right iliac fossa. Pulse 102, temperature 102.2. I put her on No. 1 every fifteen minutes, which brought about eight operations from bowels, and continued the next day the same treatment, with like results, when I substituted Nos. 2 and 3 for No. 1, but lengthened the intervals of the dosage a little too long and too soon, and we had a little elevation of temperature for a day or two only. When I saw her on January 8, after eight days of treatment, I found the temperature normal and it continued so. I saw her three more times during the next week and then discharged her.

Case 5.—Traveling man, age 39 years. This was a peculiar case; the patient, stout and robust, came home on February 24, complaining generally with gripe symptoms; he came into my office for medicine and again on the 25th, he being up and around all of the time. After forty-eight hours all aches, pains and chilliness subsided, but on the 26th he felt "tough," and on the 27th I was called in to see him. Found him stupid and glum, very bilious; the skin, white of eye, etc., at times

being very yellow. That morning I took his temperature for the first time and found it 102, pulse 72 and regular, breathing easy, tongue coated down center, breath very offensive. There was no pain in right iliac fossa at all, but there was decided tympanites. I pronounced the disease to be perambulating typhoid. I immediately put him on No. 1 that evening; the temperature was 102.6, pulse 78. On the 28th the pulse was 78, temperature 101.4 A.M. He had rested fairly well, had seven or eight stools on the preceding day and in the evening his temperature was 102.8 and pulse 96. In spite of my directions he was given the tablets only every half hour. He rested fairly well that night. On the 29th the pulse was 96, temperature 103. I ordered No. 1 to be continued without fail every fifteen minutes, and if his bowels were not too frequent, two to be given at a time. Tympanites subsided and he was allowed to get up as he had complained of no ill feelings. I then put him on No. 3. There has been some nose bleed during the day. This patient had a normal temperature on the thirteenth day of treatment, both morning and evening; no tympanites; no soreness; no fiery-red tongue. He had some hallucinations once in a while during his illness. He heard a train pass for the first time, although he only lives 150 yards from the railroad. He bled three times from the kidneys; hematuria. I gave him small phial of sanmetto and hydrang. lith., which checked this in forty-eight hours. He took No. 2 almost all the time during the attack. He complained of the throat and mouth, and kept constantly spitting, so I ordered a wash of listerin and hydrastis Canadensis.

Thus I have treated five cases of undoubted typhoid fever by the Woodbridge method without a death and with results which are not possible by any other method, and with every case I treat I am more and more satisfied and convinced that this treatment is the treatment *par excellence*. It is the richest possible boon for the victims of typhoid fever and I shall use no other. When asked recently by another physician if I believed it would do all that was claimed for it, I answered: "So certain am I that were I unfortunately stricken with typhoid fever I would not trust myself to the care of any physician who was not an expert in the management of the disease by the Woodbridge method."

A CASE OF COR BOVINUM AND HORSE-SHOE KIDNEY—NECROPSY.

Read before the Iowa and Illinois Central District Medical Association, April 9, 1896.

BY A. M. BEAL, A.M., M.D.

MOLINE, ILL.

On Jan. 3, 1896, Dr. B. F. Hall and the writer, assisted by Drs. W. K. Sloan and G. G. Craig, conducted a necropsy on the remains of O. N. R., an American, aged 43 yrs. 5 mos., which presented excellent specimens of the so-called cor bovinum and the horse-shoe kidney.

The heart was found to weigh forty ounces and measured eight inches in length, five inches in breadth, four inches in thickness and fifteen inches in its greatest circumference. The hypertrophy was due mainly to an increase in the muscular tissue of the walls of the ventricles, and no indications of degeneration of this tissue could be found. The hypertrophy was so nearly uniform in the walls of the two ventricles as to preserve quite completely the symmetrical appearance of the organ. The right ventricular wall was half an inch in the greatest thickness; the left, one and one-fourth inches. The columnæ carneæ of the right ventricle were much hypertrophied. The capacity of the ventricles was about normal. The aorta was very much dilated in its ascending portion and arch, measuring one and three-fourths inches in diameter, and there was marked failure of coaptation of both the aortic and pulmonic valves. Calcareous degeneration in the aorta extended from the valves upward an inch or more in such degree that scales or plates of the deposit fully one-half inch square could be detached.

The liver and spleen were much congested and

hypertrophied, the former weighing seventy-two ounces and the latter twenty-three ounces. The lungs were badly congested, particularly the right one, which was quite generally adherent and so atrophied from pressure that it had lost nearly one-half of its original volume.

Anatomically the curiosity of the subject was the kidney, which was of horse-shoe type. This organ, commencing at the usual place on each side, extended around over the spine and vessels in the form of a complete horse-shoe, and was twenty and one-half inches in length and weighed twenty-four ounces. It presented very little variation in thickness or breadth from one extremity to the other. The isthmus was true kidney tissue and there could be found no sinus or depression, separating the organ into two parts. Circulatory anastomosis was complete and there was but one arterial trunk, which sprang from the aorta at about the usual place of origin of the renal arteries, and divided into two branches at its junction with the kidney directly in front of the spine. Each renal arm possessed a distinct pelvis facing anteriorly and somewhat toward the spinal side, from each of which sprang a ureter, which passed downward anteriorly. At each extremity of the organ was situated a supra-renal body of about normal size, and near the left extremity was a cyst containing about two ounces of clear serum, which was probably formed by the occlusion of a uriniferous tubule.

Functionally, this anomaly of a kidney had been perfect, as its secretory process had been perfectly normal, except as disturbed by sympathetic congestion and a great excess of lithiates or urates. Its tissue was remarkably healthful, considering the circulatory disturbances to which it had been subjected and the great excess of urates with which it had to contend, so that if good blood could have been properly supplied to it, the organ would have performed its function without a fault. It was only a congested kidney, with no evidences of degenerative nephritis, and certainly did not figure as an etiologic factor in the development of the cardiac hypertrophy, which is the condition of greatest importance in this case.

The pathologic condition in cardiac hypertrophy can generally be determined with a fair degree of certainty, even during life, but the pathogenesis is often very obscure.

The indications are, that in this case atheroma or arterio-fibrosis figured in the development of the cardiac hypertrophy. Degeneration could be detected, upon careful observation, in other parts of the arterial system than the region of the aortic and pulmonic valves. There is no rheumatism or rheumatic endocarditis, but there is a distinct history of symptoms that indicate increased arterial tension for a long period prior to the recognition of any heart lesion; so that it seems proper, in the absence of any other indications, to attribute the hypertrophy to disease of the arterial coats. This appears to be one of the exceptional cases wherein the kidneys were not seriously involved. Detection of the trouble was thus rendered the more difficult. In the usual case, with pronounced albuminuria and other indications of epithelial change, the cause can be more readily traced. The absence of these kidney conditions, however, may be due to the fact that the vascular changes have only involved other organs. In studying the etiology of atheroma and arterio-fibrosis, we find that the fibroid diathesis is most intimately associated with lithemia or uric-

emia. Whatever tends to produce decay will tend to produce these conditions, and a long train of causes could be enumerated, but the limits of this paper will necessarily confine our remarks to uricemia, or the uric acid diathesis, as that is the one that seems to have figured in the case under consideration. There can be no question as to the lithemic condition of the patient during the last six months of his illness. This, however, might have been a result rather than a cause, but careful and systematic inquiry reveals the fact that the symptoms of uricemia were present during the entire course of the cardiac difficulty and for a long period prior to its development, and a careful study of the family history indicates its heredity.

As to heredity in this difficulty, observations during the last year on ten cases of uricemia, with more or less cardiac disturbance, gave a distinct history of heredity in eight. This is probably above the usual ratio. The trouble seems to be more frequent with men than women, and it is found that laboring men do not escape, especially shop hands. This condition always represents defective oxidation and plays a more important part in the etiology of disease than is generally recognized. It will creep on slowly and stealthily at times, and is often recognized only when it has wrought serious disability. It is a prolific source of gastro-intestinal troubles, and the individual who fails to recognize this morbid element when it is the cause of dyspepsia, will be grievously disappointed in his prognosis and therapeutics, as will also the individual who fails to detect the increased arterial tension in the early stages of arterio-fibrosis. My paper is already becoming too long and I have been able only to offer a few suggestions, which it is hoped will stimulate the inquiries of others in this most important subject.

SELECTIONS.

A Neurologist's Farewell; Valedictory to the Graduating Class.—

Back in the old homestead under whose kindly roof and within whose cherished walls you were sheltered from earliest childhood till the time came when you went out into the wide, wide world to begin the making of your fortune and to work your way to fame, perhaps, there sits at this very moment, doubtless, one who, slowly rocking to and fro in that cherished room which first heard the sound of your childhood's earliest prattle and witnessed your first feeble efforts at getting on in the world, is thinking, thinking, thinking only of you. Boys, it is your mother, or one who sustains to you the similitude of that sacred relationship. It may be your mother is among the saints in heaven and that her place is filled by an older sister or some other relative, or a nearer and dearer one far than all other. Whoever it may be, it is a woman. Some woman's heart and the blessed spirit of a woman's love has followed you here to-night.

It may be the fair faced, sweet eyed girl you left behind you at the gate of her father's house with warm hand press, an affectionate kiss and a manly promise to do your duty. If so, her noble injunction, "John, no matter how much I shall want to see you, don't come back without your sheepskin," has been one of the inspirations that has brought the triumph of this hour.

When you left your home, your father, too, who himself had learned and proven the value of character to a man working his way through the world, sterner and less tender perhaps in his manner, but no less sincerely interested in your welfare, said: "In the battle of life before you, be a man, my boy." "Be a hero in the strife." Do your duty. Be true to the principles of honesty, integrity and truth. Work and you will win. He said, perhaps not in words, but in heart:

"To thine own self be true
And it must follow, as the night the day,
Thou canst not then be false to any man."

And your mother, in her heart of hearts, what did she

say to you, my boy? She said, or felt, as that Roman matron felt and said to her son, as she bade him farewell and sent him to the front where the banners of Caesar waved and the victorious eagles of ancient Rome were to float triumphant above the shout and din of battle and scenes of carnage, "Return with your shield or on it." And so does every modern mother say. She loves her son, but she would rather see him die in the strife than be a coward in the battle of life.

Gentlemen, you have won the fight. You may now go home with the trophies of victory. But this is but the first engagement of your campaign. You have endured its discipline and trials so far with persevering fortitude and admirable courage. You have marched into an unknown country, conquered it and made yourself its masters. I myself have led you from the fourth ventricle, the seat of origin of most of the cranial nerves, through the *iter a tertio ad quartum ventriculum*. You have surveyed with me the bridging commissures of the former and the valve of Vieussens that covers the latter. We have lifted up the fornix, found and removed the choroid plexus on its margin, and the *velum interpositum* beneath. We found the lyre there also, and you will find liars innumerable in your pathway in the world outside. In this vicinity underneath we found the corpora quadrigemina, and the little fourth nerve, and close by laterally and a little anteriorly, the geniculate bodies, and superimposed we found and removed the pineal gland with its sandy concretion which Descartes supposed was the seat of the soul, because, I presume, he always found grit in it, which every true soul is supposed to have, and which you must all have, just as a chicken must have "sand in its craw," to live in this life of conflict in which the fittest survives, the best and truest fighter wins, while the unfit, the weak, the craven and the cowards fail and die.

You went into the foramen of Monroe and the lateral ventricles, into the basal ganglia (thalamus opticus, the corpus striatum) and the internal capsule, the external capsule, the claustrum and the insula on either side nigh them. You took a last view of the caudate and lenticular nuclei, the linea semicircularis before the operculum and the fillet of Reil, you followed me from the cortex down the motor tract between the caudate and lenticular nuclei and optic thalamus into the crura cerebri and under the Pontine Arch of Varolius into the decussation of the pyramids and saw the place of the lemniscus and back again to American soil, whence we started. You have made a neurologic excursion, a campaign of conquest, into the territory of the cerebrum and have won a victory. You voyaged over the circle of Willis up into the country of the Sylvian fissure, followed the irrigating artery of the contiguous territory, the anterior and middle lobes of the cerebrum, and studied some of its diseases which science seeks to conquer.

You traced the tractus opticus from the chiasm and beyond in the retina to its lair in the quadrate tubercles, geniculate bodies and the occipital lobes. You have looked with me from the mamillary eminences and between commissures of the thalami down into the third ventricular cavernus with naked eye or in fancy wandering, and crossed laterally over ventricular territory into the "body" route of the Hippocampi majores. You sailed "around the horn" as it were. You have explored the convolutions of the psychomotor centers and their motor tracts, and the sensory tracts through the optic beds, and into the cerebellum by means of the three peduncles, and searched for the foes of health that lurk about these regions. You have stood faithfully around the demonstrator's table of our worthy colleague and your capable leader, Professor Keiffer, and been led along arduous pathways to glorious victory by each member of the faculty and they each and all commend your industry, your fidelity, your zeal, and a body of distinguished visitors has especially commended your enthusiasm.

In the campaign, you have acquitted yourselves like true soldiers of science, and in all the other lines of duty you have likewise, as the review examinations on which we base the bestowal of these parchments testify. They are you trophies and our awards of merit. If you labor as diligently, as faithfully, as courageously hereafter as you have done to this hour in all the campaigns of the battle of life before you, you will be victorious. And when you sit down to take a retrospective view of the conflict and your part in it, as men are wont to do, and count up your triumphs and your failures, your weaknesses and your sins, and your strong efforts resistive of life's temptations, as all good men sometimes do, I trust that you will find that you have been faithful to the sacred trust these parchments impose upon you, that you have ever stood in all your dealings with mankind upon the high "vantage ground of truth," for no pleasure is comparable, as Bacon said, to such an attitude before the world. That you will have been virtuous, as your high and honorable calling demands, in all adver-

sity remembering and getting the reward of the well known fact that,

"The good are better made by ill,
As odors crushed are sweeter still,"

that you may glean from your life's trials and duties the true advantages of experience, growing wiser with years, subtler, deeper, and more logical and efficient in all that pertains to your own and your patient's welfare.

You have gone over much cerebral territory than I have enumerated. You have traversed the *terra incognita* of the soul's dwelling place in the seven layers of the gray matter and as you studied the ganglion cells of the gray cortex and marveled at the myriad cells for reception and emission of cerebro-psychic impression, you have realized how wonderfully wrought is the brain of man and come to comprehend with the physician's insight, "by sight of science," how, when time, or disease, or toxic agents touch these centers of mental impression and expression, normal function fails and is perverted in this supreme mechanism of the Great Architect, just as in the lesser mechanisms of puny man's contrivance. You have seen a center clogged by a clot of blood about and below the paracentral lobule and further down the Rolandic fissure and motion in the leg has ceased, and further down the bordering convolutions of the Rolandic fissure thus pressed upon, the hand has lost its cunning; if lower still the power of word expression and ideation has failed and if further back in the medulla the tongue has "cleaved to the roof of the mouth" and the heart and lungs have refused to do their normal duty. An aneurysm, an embolus or thrombus an extravasation or a focus or foci of softening has wrought this ruin in motor or vital centers of the brain; or the psychical centers from the same or other cause have been gravely pressed upon and the machinery of mind has stopped stock still or gone on with halting and perverted movement, with the mentality perverted and transformed, as in insanity or delirium. You have seen the effect of the unseen toxic touch of the intangible virus of a fever or a fatal drug on this wondrous cerebrum or its meninges, and finally you have seen how "the poor brain doth, by the idle comments that it makes, foretell (to you) the ending of mortality," when the disorganized blood of typhoid or typhus carries poison in lieu of nutrition to the ganglion cells of the gray cortex whose life in the organism is the true physiologic blood thereof.

All this and much more have you noted with me during the course which ends to-night. You have gone with me down the motor columns of the spinal cord, followed the direct and the pyramidal tracts and the posterior and likewise lateral sensory columns and noted their peculiar diseases revealing differing symptoms according to locality, as individuals do speech, according to the country of their birth and residence.

You have noted here especially the great reflex centers, particularly in the lumbo-sacral spine, the cilio-spinal centers of the cervical area and the vital reflex centers of the medulla and many of the nerve origins of the medulla and pons region. You have studied their significance in health and disease, appreciated their signal aid in diagnosis and wondered again at the intricate mechanism and nice adjustment to end in the machinery of man, comparing it with the machinery of man's contrivance; you have thought with Alexander Pope how,

In human purpose, though labored on with pain,
A thousand movements scarce one purpose gain,
In God's one single can its end produce,
And yet serve second to some other use.

Such is the mechanism of the cerebro-spinal axis, to say nothing of its attendant system of sensitive nerves in the sensory and motor and sympathetic systems with the wonderful ganglionic centers of the latter. But this neural journey into the vast territory of the neurones, neurils, cells and proliferations must end, like our most pleasant companionship of the past year. We have together fought away many obstacles and blazed many pathways in companionship with each other. We have marched through neurologia and neuropathia, psychiatria, and psychopathia to the open neurologic sea.

Besides all this you have looked with microscopic vision into the infinitely minute cosmos of the cerebral hemispheres, mesocephalon, etc., and spinal cord of man, and seen the potentiality of ultimate cells and the wondrous conducting power of microscopic strands of nerve fiber. You have with mental vision gone further, "where no eye can see, no glass can reach." You have heard this faculty "expatiate free o'er all this scene of man; a mighty maze, though not without a plan," as your progressing study proved.

In the great mechanisms of mind, sensation, perception, reflection, emotion, and the motor, nutritional and metabolic movements in the domain of the cerebro-spinal with its attached trophic and sympathetic systems, you have found indeed, a "vast chain of being which from God began" and dis-

covered how "all are but parts of one stupendous whole," like the great universe to which Pope referred, "whose life the blood is and the nerves the soul," as we know by sight of physiologic and chemico-biologic science, and the Roentgen rays of advancing science are constantly clearing our vision into the depth of things pertaining to medicine. — C. H. HUGHES, M.D., Professor of Psychiatry and Neurology, Barnes Medical College, and President of the Faculty.

SOCIETY PROCEEDINGS.

Tennessee State Medical Society.

Annual Meeting held at Chattanooga, Tenn., April 14-16, 1896.

FIRST DAY.

The Society was called to order by DR. D. E. NELSON, Chairman of the Committee of Arrangements.

HON. GEORGE W. OCHS, Mayor of Chattanooga, delivered an address of welcome to the city, followed by an address by DR. GEORGE A. BAXTER on behalf of the Chattanooga Medical Society. The addresses were responded to by DR. J. S. NOWLIN, of Shelbyville.

PRESIDENT G. C. SAVAGE, of Nashville, then took the Chair. DR. T. J. CROFFORD, Memphis, read a paper on "Vaginal Hysterectomy." It was accompanied with a large number of drawings illustrating the subject. The principal point brought out was that every incision may be made and every ligature applied under the direction of the sense of sight.

DR. T. HILLIARD WOOD, Nashville, read a paper on "The Treatment of Ulcers of the Cornea."

DR. BENJAMIN BRABSON CATES, Knoxville, read a paper on FRACTURES OF THE BONES ENTERING INTO THE FORMATION OF THE ELBOW JOINT.

Fractures of the bones entering into the formation of the elbow joint may be confined to any one of the bones, or it may involve all of them simultaneously. The symptoms of fracture of any of the bones at the elbow are theoretically simple, yet practically offer difficulties, due to the anatomic structures surrounding it, and again to the distance from the surface of some parts of the bones entering into the formation of this joint, as in the coronoid process of the ulna and the neck of the radius. The diagnosis of injuries of the condyles of the humerus not complicated by luxation of the bones of the forearm, if seen before there is much swelling, can be differentiated by grasping the condyles between the fingers and rubbing them to and fro. The condyles may be wider on the injured side. Should the fracture extend through the base of the condyles there is shortening. When the olecranon process is fractured there is gaping between the fractured process and shaft of the bone. There is not always the complete loss of power of extending the forearm. Should the coronoid process of the ulna sustain a fracture, it might be felt in thin subjects as a loose body in front of the joint.

If the upper extremity of the radius is fractured the close proximity of its head to the surface offers the surgeon a better opportunity for manipulation; since by pressing upon the head of the radius with the thumb of one hand and grasping the hand of the patient with the other, he can by pronation and supination tell with a fair degree of certainty whether the head or the neck of the bone is the seat of injury. If simple and seen before there is much tumefaction, and when involving the lower extremity of the humerus, the application of the roller bandage and an internal rectangular splint, or an anterior angular splint well padded, with a cap for the posterior surface of the elbow, may be applied. If the olecranon is fractured the object is to keep the fragment in contact with the shaft of the ulna, which can be done by means of compresses with adhesive strips, fortified by a figure of eight turn of the roller bandage and keeping the arm extended by means of a straight splint applied to the anterior surface of the arm and forearm. Should the trauma be of such a nature as to permanently injure the structures of the joint, as often happens in compound fractures, forming a liability to ankylosis, the arm should be placed in a position the most useful, which is nearly a right angle.

DR. J. S. NOWLIN, Shelbyville, read

A REVIEW OF THE PAST AND PRESENT PATHOLOGY AND TREATMENT OF UTERINE DISPLACEMENTS,

in which he says: "I do not believe that uterine displacements ever require treatment of any kind when the organ itself is not diseased. When symptoms are present it is the result of disease and not displacement. I do not believe that the retroposition ever interferes with the blood or nerve supply sufficiently

to produce disease or pain. Rational treatment must be directed to the morbid condition and not to the position."

DR. T. J. HAPPEL, Trenton, read a paper on

IMMEDIATE OPERATIONS.

He cited cases of crushing injuries, etc., and makes the following deductions: Most important of all is the fact that each patient, and each injury, must be its own rule. No arbitrary rule can be laid down, by which to fix the time for an operation in cases of severe injuries. In slight injuries, with no shock, or very slight shock, the sooner the necessary attentions can be given the patient, the better. The prognosis in such cases is favorable. As a rule, patients from 10 to 25 years bear operations better than those younger or older. One more point to which I would invite attention is the fact that the presence of pus in operations for railway injuries is no proof of a want of proper cleanliness, or of proper antiseptic precautions. Crushed wounds, such as we ordinarily encounter in railway injuries, generate pus; that is, they heal by a granulation process in spite of our antiseptic or aseptic surgery. This condition of things, the failure to unite by first intention, is due in most cases to shock, which impairs nutrition, lessens the general vigor, and brings about blood changes, thus making a fitting soil for the growth and development of pyogenic cocci. Chloroform is the anesthetic employed in all of my surgical work.

DR. I. W. MOODY, Shelbyville, read a paper on "Croup."

DR. G. C. SAVAGE, Nashville, delivered the Presidential address: "Medical Progress; Its Helps and Hindrances." (See JOURNAL, page 799.)

DR. J. B. F. DICE, Morristown, read a "Report of a Case of Neurotic Bladder Trouble and subsequent Pyelonephritis; relieved by Nephrotomy."

DR. K. S. HOWTELL read a paper on

CHRONIC GASTRIC DYSPEPSIA.

Rapid eating and imperfect mastication are the chief exciting causes of all forms of dyspepsia. Mental strain or worry, etc., belong especially to the neuroses. The pathology of functional dyspepsia consists of either an atonic condition or an exaggerated irritability of the nerve supply. The treatment by dieting plays an important part, but may be too strict and too prolonged. Digestion begins in the mouth and any error as to cleanliness, thorough mastication and insalivation should be corrected.

Adjourned until 9 A.M.

SECOND DAY.

DR. S. S. CROCKETT, Nashville, read a paper on "Cancer of the Breast." The author held that since the atypical cells of cancer must originate from preëxisting atypical cancer cells, if all the atypical cancer cells are removed, in cases of cancer, there can be no so-called recurrence of the trouble. But if atypical cancer cells are left, these may proliferate and thus produce a so-called recurrence of cancer.

DR. H. J. WARMUTH, Smyrna, gave a paper on "The Radical Operation for Cancer of the Breast."

DR. W. F. GLENN, Nashville, read a paper on "Hypertrophy of the Prostate."

DR. G. B. THORNTON, Memphis, considered "Suburban Sanitation."

DR. G. W. DRAKE, Chattanooga, treated of "The Röntgen Rays: Their Prospective Utility in Physiology."

DR. A. B. COOKE, Nashville, discoursed upon "Fissura in Ano."

DR. C. M. SEBASTIAN, Martin, considered "The Germ Theory of Disease."

DR. J. L. CROOK, Jackson, dealt with the subject of "Sprained Ankles."

DR. J. A. CROOK, Jackson, took up

THE RATIONAL TREATMENT OF TYPHOID FEVER.

The paper contained a report of several cases of typhoid fever successfully treated by the so-called Woodbridge method.

THIRD DAY.

DR. W. S. SCOTT, Dickson, dealt with "Anomalies of the Umbilical Cord."

DR. PAUL F. EYE, Nashville, read a paper on

SURGERY OF THE PANCREAS, WITH REPORT OF A CASE.

The conditions deserving attention in a surgical way may be mentioned as those commonly found in analogous organs, as the liver, etc., such as carcinoma, sarcoma, abscess, hydatids, cysts, etc. Unfortunately, such affections as carcinoma, sarcoma and abscess of the pancreas have only been diagnosed after death, postmortem examinations revealing their true character. Wounds of the pancreas, partial rupture of the organ and severe contusions have been diagnosed and success-

fully treated. Portions of the organ, presenting themselves in stab and gunshot wounds, have been removed with complete recovery. The affection, however, with which we are best acquainted is cyst of the pancreas. Some of the causes which produce cyst of the pancreas may be enumerated as follows: Obstruction of the pancreatic duct, either by calculi or cicatricial contraction, the product of inflammation; displacement of the organ; pressure by tumor or aneurysm upon the organ or its duct, and traumatism.

The diagnosis of cyst of the pancreas is by no means an easy matter, and not a few cases are only cleared up by an exploratory incision through the abdominal walls. These cysts have been mistaken for hydatids of the liver, ovarian tumors, and in a few cases where the cysts were over an artery, for an aneurysm. It is only in a few cases where the cyst has attained a large size, that a diagnosis can be assured with any certainty. The history of the case should be carefully studied and the position of the tumor clearly outlined. The tumor is generally seen in the epigastric or left hypochondriac regions, having an elastic tense feeling, and is of rapid growth. Diarrhea and emaciation follow, due possibly to pressure from the cyst walls, and interference with the functions of the gland. Pain is experienced in the region of the pancreas, and to this some authors add a muddy complexion of the skin. A valuable diagnostic point is brought out in the insertion of a hypodermic needle into the cyst walls, the evacuation of the fluid and the examination of the same; the fluid in the great majority of cases being of a chocolate hue. In several cases reported the tumor was of large dimensions, the cyst containing nearly two gallons of fluid. The treatment of pancreatic cysts is divided into incision of the sac and drainage; the walls of the cyst being attached to the abdominal parietes, a drainage tube inserted, this being constantly shortened until finally removed, and the complete removal of the cyst. The objection to drainage by incision of the cyst is in some cases the establishment of a permanent fistula, the escape of the fluid into the peritoneal cavity, and the re-accumulation of the cyst after evacuation.

The ideal operation is the complete removal of the cyst from the abdominal cavity, as it removes these objections.

The essayist then reported a successful case of operation for removal of a cyst of the pancreas. The cyst occurred after the receipt of a trauma, in a patient who had previously been in good health, and seemed to indicate that pancreatic cysts can be produced by traumatism. The author believed this to be the second recorded case in which such a pancreatic cyst was successfully completely removed. During the operation the intestine was denuded of its mesentery for a distance of eight inches. The denuded gut was surrounded with an omental graft, with perfect success.

The paper and report were discussed by Dr. W. K. Sheddan, Williamsport, and closed by Dr. Eve.

Then followed "Professional Fads and Faddists," by Dr. W. K. Sheddan, Williamsport; "Treatment of Injuries of the Brain," by Dr. D. Y. Winston, Clarksville; "Indications for Trephining," by Dr. E. A. Neely, Memphis; "Report of a Case of Gallstones," by Dr. T. R. Moss, Dyersburg (see JOURNAL, page 775); "Pernicious Malarial Fever," by Dr. C. W. Womack, Chapel Hill; "Treatment of Hemorrhoids," by Dr. H. R. Coston, Fayetteville.

Dr. R. J. McFALL, Cumberland City, considered "Sciatica," in which he says: It may be a symptom of pregnancy, of affection of the retro-peritoneal lymph glands, of an intra-pelvic tumor, of foreign substance in the sigmoid flexure of the colon, and of a fecal mass.

Chicago Ophthalmological and Otological Society.

Regular meeting held March 10, 1896.

DR. GRADLE in the Chair.

Minutes of the last meeting were read and approved.

There were twenty-five members and visitors in attendance.

Dr. J. B. Loring was elected a member.

The following amendment to the Constitution and new by-law was adopted:

Article III of the Constitution. "The members of this Society shall be graduates of regular medicine, who shall have practiced ophthalmology or otology for at least three years before the time of applying for membership."

Section VIII of the By-Laws. "Any member who shall remain in arrears for dues or assessments for more than six months after notification by the Secretary, shall be considered as having resigned."

On motion, the Secretary was instructed to arrange for a place of meeting suitable for all members.

Dr. Wood then reported

A CASE OF PIGMENTATION OF THE CORNEA.

This rather rare condition is illustrated by the following case: Mr. D., aged 56 years, came to Nov. 29, 1895, and from him Mr. Wood obtained this history: He has always been near-sighted and at school his eyes were weak and he was unable to study with any satisfaction. Has always had more or less vertigo and frontal headache, but until recently never noticed any redness of the eyes or sticking together of the lids in the morning. Two months ago he began to have supra-orbital pain on the left side extending to the top of his head. This hemimeria was very severe and continued for seven weeks, with some remissions, until a week ago, since when it has been continuous. For most of this time he was not able to sleep, and then only when under the influence of narcotics. He never had any pain in the right eye or right side of the head. After the second attack of pain he noticed that his eye was quite red, and that the vision was not quite as good after the pain had somewhat subsided. It was much diminished after the last attack, just before Dr. Wood saw him.

Present condition: Vision of the right eye=fingers at 4 feet; right, 15-200; with his reading glasses he reads Jaeger 4, but can not distinguish even the coarsest print with his left eye. O. S. T+2, shallow anterior chamber, motionless and semi-dilated pupil, several small posterior synechiae, hazy, infiltrated cornea and doubtful cloudiness of the lens. The cloudy cornea, upon an examination with a strong Zeiss lens, focal illumination, window-reflex and the employment of fluorescein and pyoktanin solutions was found to consist, first, of a diffuse interstitial infiltration about the center of the cornea, and of a punctate keratitis with the dots arranged in the usual pyramidal fashion, the base 6 or 7 mm. broad, intersected by fine vessels and the apex, where the spots are few and scattered, reaching almost to the middle of the pupil. No vessel advances into the cornea more than 2 mm. from the limbus and some of them appear to end in the dots, forming a picture like that of nerve filaments and the corresponding tactile corpuscles. Both the ciliary and scleral vessels are much engorged and the eyeball is tender. The condition of the fundus can not be made out.

With the exception of a marked refractive error the right eye appeared normal. Dr. Wood at once applied a 1 per cent. mixture of eserine to the left eye and gave $\frac{1}{2}$ per cent. solution with cocaine for use at home until the patient could decide about the operation which he suggested. On December 2 Dr. Wood did a peripheral iridectomy upward. Bleeding occurred from the iris and the anterior chamber was filled with blood. Two days subsequently the tension was considerably less (the wound having not yet closed); the pains had gone and the patient was able to sleep without having taken analgesics. The signs and symptoms of glaucoma now steadily disappeared, the aqueous cleared up until January 14 V. O. S.=15-200. The eye is very quiet and the man is able to do some work. The field of vision for white, left, is, however, greatly reduced and comprises an area bounded by the twentieth parallel. There is an opacity in the upper fourth of the crystalline which looks as if, in tearing away the iris from the lens, the anterior capsule had been injured. The ophthalmoscope, although the media are still hazy, shows a marked excavation of the disc. Feb. 3, 1896, the lens is now quite opaque, but the eye is absolutely quiet; tension normal or slightly increased; there has been no trouble since the last report. There is a rent in the capsule, corresponding in position with the cut edge of the iris, the edges of which are everted and faintly pigmented.

Jan. 21, 1896. In the cornea a little to the nasal side of pupillary center is a large, isolated, 1 mm. broad, rounded mass of pigment and toward the outer edge of the pupil a smaller one, also discrete. At the edge of the pupil when at its average size are minute scattered deposits, some of them arranged in chains, but most of them irregularly dotting the cornea. Then, directly downward is a perfectly clear band of corneal tissue about 2 mm. wide, entirely free of pigment, as we proceed still further downward from the pupil toward the limbus the fine dots once more show themselves until just before the sclero-corneal junction is reached the peculiar picture is presented of what seems to be round corneal dots undergoing a process of pigmentation. We then reach an area of hazy cornea, 6 mm. by 3, bounded below by the sclera. This contains a large number of capillaries, plainly seen to be extensions from the anterior sclera vessels, running past or into a regular row of medium-sized dots, about thirty in number that, are placed almost equi-distant from the limbus corneae and one another. Some of these, especially at the center, are jet black, some are grayish and some are whitish, in all stages of pigmentation.

March 6, 1896. A portion of the diffuse inter-punctate hazi-

ness, just referred to, has disappeared, so that an entirely transparent cornea is seen in which the black dots, chains and irregular figures are planted.

The best descriptions of pigmentation of the cornea are given by Weeks, Treacher Collins, Vossius and Lawford. We notice in a majority of cases recorded by these authorities, 1. that they were mostly examples of some form of glaucoma, with increased and persistent intra-ocular tension; 2. there was bleeding into the anterior chamber; 3. there was brownish, smoky or other discoloration of the cornea, and 4. pigmentation was found at the limbus corneæ and in other parts of the anterior segment of the eyeball.

DR. PINCKARD had seen the case by courtesy of Dr. Wood. The central deposit looked very much like an anterior synechia that had been torn loose. There was no question in his mind that the deposits were on the posterior surface of the cornea. With a short focused lens, half an inch, they could be accurately placed on Descemet's membrane.

DR. HOTZ had also seen the patient and agreed that the deposits were on the back of the cornea. He had seen numerous cases of so-called serous iritis in which deposits on the posterior surface of the cornea had taken place. He believed that the pigment in these deposits came from the pigment layer of the iris. These deposits are sometimes so deceptive in appearance that they are taken for foreign bodies in the cornea.

DR. HALE said that in the German clinics one sometimes sees patients with pigmented corneæ, due to the tincture opii crocatæ.

DR. WOOD, in closing, said that there had never been any synechia in the case.

DR. MANN then reported cases of *purulent ophthalmia* treated by Dr. Scott's formula. The method adopted was strictly in accordance with Dr. Scott's instructions as presented to the Ophthalmological Section of the AMERICAN MEDICAL ASSOCIATION in 1894. The treatment consists, in brief, of cleansing with cotton for from 15 to 20 minutes, then cold applications and the instillation of a dropper-full of the hydrastin solution. Dr. Scott claimed for the treatment, that in acute cases abortion took place in from three to five days, and in older cases in about a week.

DR. WÜRDEMAN, of Milwaukee, said that the hydrastin was beneficial, but that it is not more so than boric acid or similar antiseptic solutions used in the same way, and he does not find that it has a specific influence in mitigating conjunctival inflammation, or that it materially cuts short the course of the ophthalmia. In a personal letter from Dr. Scott to Dr. Mann, dated March 5, 1896, he says that Dr. Würdemann is the only one who has failed to have uniformly good results; and that Dr. Scott had received over one hundred letters from gentlemen over the country whose results have been uniformly good.

DR. MANN's experience was limited to a few cases, but the results have been remarkable.

Case 1.—Baby: first seen August 8, when two weeks old. The disease had existed since the fourth day. It presented the ordinary appearance of an ordinary purulent ophthalmia of mild type. Prior treatment had been simply cleansing. The corneæ were clear; swelling and discharge moderate. A solution of boric acid was ordered every half hour, and a 2 per cent. silver solution applied daily. In the next two weeks there was not much change, although the silver was increased to 6 per cent. By this time the left cornea had become involved, followed in a few days by the right. The condition of the lid had slightly improved, but there was still considerable discharge. September 1 to 10, the case was in Dr. Starkey's care during Dr. Mann's absence from the city. Dr. Starkey continued the silver solution and used as high as 10 per cent., but with no lasting benefit. Both corneæ were perforated; anterior staphyloma in the left with anterior synechia. In the right there was a small perforation with anterior synechia. With Dr. Starkey's approval the hydrastin solution of Dr. Scott was ordered. The result was immediate improvement. The mother said there was no more pus formed after the first drop was used. When the baby was seen the next day there was only a slight muco-purulent discharge, and in forty-eight hours there was no pus, nor did any reappear. Dr. Mann feels satisfied that if the hydrastin had been used earlier the baby would now have two good eyes.

Case 2.—Baby, with purulent ophthalmia of moderate intensity, which had existed about two weeks. Both eyes were affected. Directions were given to clean the eyes frequently with boric acid solution and to use the hydrastin solutions four times daily. The mother was told that if the eyes did not seem a little better the following day to return. This was on Thursday. The following Monday she returned and Dr. Mann found on examination only a very slight purulent discharge, which entirely ceased within a week from the com-

mencement of the hydrastin solution. In this case no silver was used.

Case 3.—This case was similar to the above, but the disease was more pronounced. The lids were markedly swollen and there was a profuse discharge. Similar treatment and instructions were given as in the preceding case. Three days later the swelling was all gone, eyes wide open, only a slight muco-purulent discharge remaining. Corneæ clear.

Case 4.—Male adult. Gonorrheal ophthalmia of the right eye; the disease had existed in the right eye when the case came under Dr. Mann's care. The lids were swollen shut; there was chemosis; the cornea infiltrated. The eye was cleansed and a few drops of the hydrastin solution dropped in it. Instructions were given to have the eye washed every half hour with boric acid solution and the hydrastin solution used every three hours. The next day the swelling was some less and the amount of pus very much diminished. At the end of forty-eight hours there was no pus and but little swelling. The cornea, however, was so deeply invaded that it subsequently sloughed at the center.

All of these cases Dr. Mann had personally seen. Two of them showed very positive results. In both silver had been previously used, but in none was silver used during the same time the hydrastin solution was used. In every case silver would have been used had there not been decided improvement within twenty-four hours after the use of hydrastin. The Doctor thinks if we can get equally good results from this treatment by hydrastin, it should be preferred to the treatment with the strong solutions of nitrate of silver. The disadvantages of silver are that it requires a skilled hand in its application, and it is dangerous to the cornea. With the hydrastin solution there are no dangers to avoid.

DR. COLBURN does not advise the use of silver in any form. He has not used it for years, nor has he used the hydrastin solution. He has never had a cornea infiltrated in his experience. His method of treatment is thorough cleansing of the eye with a pipette with a neutral peroxid of hydrogen solution, 1 to 3, in water, this being followed by a hot peroxid of hydrogen solution, and finally filling the eye with borated vaselin. The most important part of the process is thorough cleansing with the peroxid of hydrogen.

DR. WÜRDEMAN read from Dr. Scott's original article: "This plan has robbed purulent ophthalmia of all its terrors. In all cases there is a marked improvement in twenty-four hours. The patient is almost well in forty-eight hours, and is always well in ten days." Dr. Würdemann had used Dr. Scott's method in fourteen cases, but he had found that the hydrastin solution was no better than a boric acid solution. There were four cases in which the cornea became stained and ulcerations started. He had had one case recently, however, in which the amount of discharge seemed to be lessened, but he had never seen any such results that approached Dr. Scott's claim.

DR. STARKEY had seen the case spoken of by Dr. Mann and the result seemed to be marvelous from the solution. He had not been able to satisfy himself why this was so, and it was not a coincidence in the treatment.

DR. HALE said that the presence of the gonococcus in the diagnosis of the cases was of the utmost importance; that such purulent cases may not be gonorrheal in character.

DR. MONTGOMERY had never used Dr. Scott's formula, but had no faith in it. His method of treatment consisted in the use of strong silver solutions with cleansing of the eye.

DR. HOTZ had had no experience with the Scott solution. He was entirely satisfied with the results obtained from solutions of silver nitrate combined with washing of the outside of the eye frequently with water. He did not believe that any nurse or parent was able to cleanse the inside of a baby's eye, and therefore never recommended it.

DR. HAWLEY had had little experience with hydrastin in eye diseases, but had used it considerably in urethral cases. He thinks it of value.

DR. HOLMES had no fault to find with the treatment by nitrate of silver. He applies the silver once a day carefully, and cold applications were kept up the rest of the time.

DR. GRADLE spoke of the apparent effect on a case of ophthalmia neonatorum by the attenuation of the virus, that is, in a case from an old gonorrhea in the father. The resulting ophthalmia neonatorum is very different from that of a recent case in the father.

DR. MANN, in closing, said he had started out with no faith in the Scott formula, nor would he now depend on the formula alone for the treatment of any case of gonorrheal ophthalmia. But he proposed to use it in selected cases, watching carefully for any increase of the disease, in which case he would use silver as he had done before.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, MAY 23, 1896.

THE ANTI-VIVISECTION MOVEMENT.

"And God said, Let us make man in our image, after our likeness; and let him have dominion over the fish of the sea, and over the fowl of the air, and over the cattle, and over all the earth, and over every creeping thing that creepeth upon the earth." Genesis 1: 26.

"For thou hast made him a little lower than the angels, and hast crowned him with glory and honor.

"Thou madest him to have dominion over the works of thy hands; thou hast put all things under his feet." Psalm vii: 5, 6.

The cranks, with and without wheels, delight to assemble in Washington near the close of a session of Congress. They infest the rotunda, they swarm in the lobbies, they lie in wait for the passing member of Congress, and they button-hole the patient Senator in the Marble Room. No scheme so visionary, no sentiment so false, no project so absurd but it has its crank advocates, and sometimes when these vagaries come veiled in the cloak of philosophy these advocates swarm like the camp-followers of an army.

Just now the hungry wild-eyed fanatic has his mind fixed upon the passage of a bill which, if it become a law, will close the laboratories of the Public Service and stop physiologic experimentation under Governmental auspices. If this were all, the spectacle might be viewed with the same mild surprise and curiosity as that produced by the "COXEY" tatterdemalions of a year or two ago. But unfortunately, the passage of this law will be a signal for the commencement of a similar raid upon the State Legislatures, and all experimentation on animals will cease. It is needless here to recapitulate the long list of useful experiments that, performed on animals, have resulted in discoveries which have prolonged human life and reduced the sum of human suffering; for that has been ably done by many scientific men who have had a reluctant or partial hearing before the Senate Committee. The Committee having charge of the matter at the Atlanta meeting went to the root of the subject as follows:

WHEREAS, the members of the AMERICAN MEDICAL ASSOCIATION

recognize the fact that the developments of scientific medicine have resulted largely from experiments upon the lower animals; and

WHEREAS, anesthetics are habitually administered to animals subjected to painful experiments; and

WHEREAS, restrictive legislation is in our opinion unnecessary and opposed to the continued progress of medical science; and

WHEREAS, it is an unjust reflection upon the humanity of those engaged in animal experimentation to enact laws requiring them to use anesthetics and appointing inspectors to see that they do so; and

WHEREAS, far more unnecessary pain is constantly being inflicted upon the lower animals for sport and for game than in biologic and pathologic laboratories; and

WHEREAS, no evidence has been presented by those who advocate restrictive legislation showing that abuses exist in the District of Columbia; and

WHEREAS, results of great practical importance have been obtained by experiments on the lower animals made in the Government laboratories in the District of Columbia; therefore be it

Resolved, That the AMERICAN MEDICAL ASSOCIATION earnestly protest against the passage of Senate Bill No. 1552, entitled, "A Bill for the further prevention of cruelty to animals in the District of Columbia," or any modification of this Bill, unless it shall first be shown by an impartial investigation that cruel and unnecessary experiments are being performed in the District of Columbia, and that existing laws do not provide suitable punishment for cruelty to the domestic animals.

Resolved, That copies of these Resolutions, attested by the signatures of the President of the AMERICAN MEDICAL ASSOCIATION and of its Committee appointed to draft these resolutions, be sent to the Chairman of the Committees on the District of Columbia, in the House of Representatives and Senate of the United States.

(Signed)

DR. NICHOLAS SENN,
DR. WM. OSLER,
DR. GEO. M. GOULD,
DR. J. McFADDEN GASTON,
DR. DONALD MACLEAN.

From the days of Aristotle who tried the effect of various drugs on the tortoise, to the present day, when the demonstration of the pathogenic microbes has been actively made upon guinea pigs and rabbits, medical knowledge has made its great strides by means of vivisection or experimentation upon the lower animals, over which the CREATOR gave man dominion at the creation. It is quite probable that only a few of these fanatics are vegetarians and yet the only legitimate outcome of their argument would be to close the fisheries, the vast meat industries, and to allow the beasts, insects and fishes to flourish, unchecked by and without regard to the needs and uses of man.

Where, O misguided misanthropic antivivisectionist! will this thing stop? Will you draw the line on the warm-blooded animals, and allow the scientists control of the creeping things? Or will you include them also within the sacred inclosure where no experimentalist dares to tread? And the bacteria themselves, even the cholera microbe and the despised tubercle bacillus, are they not living organisms? Are experimenters to be barred from testing microbic powers of endurance? Is the fanatic quite prepared, on his exclusive bean diet, to even forbid the scientist from punishing a wicked flea or putting salt on the tail of a pathogenic microbe? Come Messrs. the antivivisectionists, let us have a clear definition of your tenets and the reasons for your alleged belief.

If experimentation on animals were for purposes of speculative science only, there might be a glimmering of reason in the outcry against it, but, on the contrary, these experiments almost without exception have the highest practical value, and the attained results are made use of throughout the civilized world immediately.

It is to be regretted that these experiments can not be made on some inanimate object, but man has not yet learned the exact nature of the vital spark, and the exact line of demarcation between the machine and that which vivifies it. We must therefore pursue our physical inquiries on living machinery, tissues having bodily functions to perform. This necessity makes animal experimentation indispensable to further progress. Biology is not yet exact; we must learn much, and the only direct avenue is through anatomic investigation and physiologic experiment.

The days of the Ptolemys, who gave the living condemned criminals to the knife of the anatomist, are over, and we have now only animals, over which the CREATOR gave man absolute dominion, for experimental purposes. Can our antivivisectionists provide a substitute? Or do they really intend that philosophic inquiry in this direction shall cease? We fear that they have moved and are moving in this matter not only without knowledge of the facts and of the great benefits which experimentation on the lower animals has conferred upon humanity, but in most cases in wilful ignorance and mischievous demagoguery.

In conclusion, we urge that as the ASSOCIATION has no standing committee on legislation, every member should at once write his Senator opposing it.

A PROPOSED INTERNATIONAL COMMISSION ON INSANITY.

It is stated in one of our exchanges that notice has been given in the British Parliament of a resolution to the effect that it is desirable in the interest of the general welfare that an international commission be appointed to investigate the causes of insanity, the rapid increase of which in all civilized countries is becoming one of the most important of the social questions of the times. Just what this proposed commission is expected to do is not stated and it is not, at first sight at least, easy to see what an international body can do to any greater advantage than one confined to a single country as regards direct beneficial results. Scientific questions, it is true, are not national ones in any limited sense, but for this very reason whatever of valuable truth is elicited in one country is at once common property to all, and therefore the chief value of an international commission would seem to be in the possible greater weight of authority that it could give to its findings and recommendations. While, however, its decisions

might have the highest scientific authority they could hardly expect to effect more than to add a little possible enlightenment to officials, rulers and legislators, and it is extremely questionable whether it would materially affect their actions to any considerable extent. The questions that would necessarily come before it, the effects of intemperance, immorality, the stress of modern civilization, the consequences of the prevalent militarism of the present time in Europe, of emigration, of popular social and religious tendencies, of special diseases, etc., have been and are constantly being discussed and investigated, and it is doubtful whether any really new data would be developed by the labors of such a commission more than by the various scientific workers at present engaged with them. The most we could expect of it would be the discussion of perhaps a wider range of statistics, and a more authoritative utterance on these subjects, provided the commission was properly composed of those whose words and opinions would carry sufficient weight. It need not be questioned that there might be a certain amount of benefit derived from an official international inquiry but no extravagant expectations will be realized, and it is not easy to see how between European nations there can be any effective international coöperation for the betterment of the existing state of affairs.

As regards America, however, there is one question that might well be an international one. Many of the European countries have long been in the habit of unloading their insane and other defectives upon us and the *rejecta* of the Continental and English asylums are to be found in nearly all our hospitals for the insane. There is no reciprocity in this, it is almost altogether one sided and we are the sufferers. If any kind of an international commission would help to do away with this imposition we certainly should be the first to welcome it.

SMALLPOX AT GLOUCESTER, ENGLAND.

The *Sanitary Record*, April 24, quotes a presentment by the April grand jury in which a demand is made for the enforcement of the vaccination laws by the Local Government Board, and that the laws be so changed that local boards of guardians be relieved from the duty of enforcing vaccination. This presentment strongly urges "the immediate vaccination of all unprotected children and the revaccination of adults as the only means of stamping out smallpox in the city."

The health officer's (DR. F. T. BOND) latest published report gives the following statement regarding the number of cases and deaths in the first quarter of 1896 as follows:

It is alleged by antivaccinators that vaccination gives no protection against smallpox. Let us see how far the experience of the epidemic in Gloucester up to the present time supports the assertion.

Up to March 27 the cases admitted into the Smallpox Hospital since June last from the City of Gloucester, and their results so far as the cases have yet terminated, are as follows: Persons attacked, 365; not vaccinated, 207; vaccinated only in infancy (chiefly adults), 158; revaccinated (fourteen years ago), 1. Deaths, 81; not vaccinated, 70; vaccinated only in infancy (chiefly adults), 11. Proportion of deaths 23 per cent., or one in five; not vaccinated, 33.8 per cent., or one in three; vaccinated only in infancy (chiefly adults), 7 per cent., or one in fourteen. Of the seventy unvaccinated deaths all but three were children under 10 years of age. Two of these three were 11 and 14 respectively, and the third was 21 years of age.

It is clear, therefore, that smallpox is a terribly fatal disease to young and unprotected children. In fact, it is a veritable *slaughter of the innocents*. Not a single death has yet occurred in a vaccinated person under 24 years of age, and death in the case of most of those who did die was attributable, in part at least, to the influence of other causes. It is, therefore, equally clear that vaccination gives a degree of protection against death from smallpox for the earlier years of life which is, for all practical purposes, nearly certain, even when it does not altogether protect against an attack of the disease.

The great majority of the unvaccinated children who recovered had the disease very severely and will be badly disfigured through life. Some of them will be blind. The great majority of 158 persons who are recorded as "vaccinated" were adults who had been vaccinated in infancy only. Many of them had very poor marks and were therefore badly protected from the first; and in the remainder the influence of their first vaccination had more or less faded through time, and yet most of these imperfectly protected persons had the disease so lightly that they will not be disfigured at all by it.

The ages of these 158 vaccinated persons were as follows: Under 10 years, 2; under 20, 42; under 30, 50; under 40, 35; 40 and over, 29. The ages of the unvaccinated were as follows: Under 10 years, 179; under 20, 14; under 30, 9; under 40, 1; 40 and over, 4. This confirms what doctors and all persons of experience assert, that proper vaccination, while giving almost certain protection during the first ten years of life, loses its effect gradually, though it gives some amount of protection throughout life, just as an attack of smallpox itself does. Only one case of a person who is said to have been revaccinated before exposure to the risk of infection is known to have been admitted into the hospital, and she was vaccinated fourteen years ago. Of all the medical men, trained nurses and all attendants who have, after being revaccinated, been brought into frequent and close contact with the disease in the city since the commencement of the outbreak, not one has taken the infection.

Instances of unvaccinated persons who have caught the disease, and of vaccinated persons who have escaped, in the same family, are very numerous. Among the above 365 cases there are a large number still in the hospital, many of whom are very ill, and among whom deaths must be expected, which will make the case in favor of vaccination still stronger than it is from the above numbers. There are also a large number of cases, both in the city and suburbs, for which there was no room in the hospital. The record of many of these cases has yet to be taken, but from what is already known of them, they will still further confirm the evidence in favor of vaccination which is afforded by the hospital cases.

The following is a portion of an article in the *London Times*, showing the active interest taken by the great national Local Government Board to secure a reestablishment of vaccinal protection in that community, and for thirty miles about:

The Board of Guardians of Gloucester is getting frightened at the disaster their fault has brought about. They issued notices to the public, for the first time in some ten or more years, urging the people to be vaccinated and revaccinated; and, getting still more alarmed, about a week since they actually decided to attempt to undo the mischief of past years, and passed a resolution deciding to enforce the compulsory clauses of the vaccination acts. It is officially stated that the Local Government Board, in view of the altered attitude of the guardians, has sent a medical inspector to Gloucester to aid, so far as is now practicable, in organizing a system of public vaccination, and it is strongly held in official minds that in vaccination and revaccination lies the only hope for the escape of the city from further spread of the disease. Dr. Parsons, one of the assistant medical officers of the Local Government Board, is the officer selected for this arduous and humane and also dangerous duty, and he is already at Gloucester assisting the local authorities in every way in his power. The Local Government Board has also issued notices to the guardians of unions within a radius of thirty miles of Gloucester, calling attention to the action they should take in preventing the danger of the importation of the disease from the infected city. The very leader of the antivaccination heresy has climbed down and has "submitted to the operation against his convictions but for the public good," probably thus saving his own skin after having been the means of putting hundreds of lives in jeopardy.

It may be stated that the Town Council from the first did their utmost by isolating the sick in hospital, by disinfecting houses, burning clothes and bedding, and placing relatives of sick in practical quarantine, to stay the outbreak. Finding the outbreak gaining, they built extra hospitals, and have now hospitals for 120 patients, but the disease continued to spread with such virulence that it was quite beyond their power to cope with it.

ECONOMY IN LIFE INSURANCE AT THE EXPENSE OF MEDICAL EXAMINERS.

The *Pacific Medical Journal* enters its protest against the reduction of the fees of medical examiners, if retrenchment is not also carried out in other directions. It says, with great truth, that many of the life insurance companies are feeling the effects of hard times. They find it necessary to economize, and have concluded to reduce the medical examiner's fee. There is not a board of directors of any life insurance company in the land that believes the medical examiner is overpaid or even sufficiently paid. Nor is there a board that believes that it would be economy to employ an irresponsible examiner.

The directors do know, however, that medical men will submit to almost any form of imposition from corporations—that if the older examiners will not submit to a reduction, there will be no difficulty in getting good men to take their places. The medical profession should stand together in this matter. For a company that pays its president \$100,000 a year, to reduce the medical examiner's fee in order to economize, is simply an insult and indignity to the medical profession. Physicians can live without the assistance of life insurance companies, but life insurance companies can not do business without the services of the medical examiner. It is clearly the fault of the profession and not of the companies if a reduction in examiner's fees is tolerated. A united profession and the fees will stand; divided and the fees will fall. Examiners should bring this matter before every medical society in the whole country, obtain the support of the whole profession, and

the companies will be compelled to economize where economy will be in the interest of the insured. Perhaps the companies could do with less extravagant and costly buildings, for instance.

THE "RABID ANTISEPTICIST" AND INFECTED BOOKS AND BANK-NOTES.

Here is a new word for the makers of dictionaries, the "antisepticist" (meaning probably the antiseptic crank), for which the editor of the *Press and Circular* appears to be responsible. The new term finds its origin in the following annotation on infected books, papers and bank-bills:

The Paris Academy of Medicine has been engaged upon the discussion of a communication by M. DU CAZAL, in which he records his experiments respecting the danger of infection from books. It goes without saying that he found abundant microbes on the pages of books, especially those lent out from libraries, and that he found it impossible to effectually disinfect them. The sequence, we assume, is that no one should read a book unless it is uncut and fresh from the press, and that, even in that case, the reader will have to run the gauntlet of a lesser army of microbes. The question suggests itself, where is this microbe craze to stop? Or at what point does it become ridiculous? Is there any article touched from morning to night in our daily life which is not open to the same objection in a greater or lesser degree than the circulating library book? The most rabid "antisepticist" accepts with satisfaction a bank-note reeking and saturated with germs, and carries it about with him into every sick chamber into which he enters. Where is the consistency?

THE JOURNAL SPECIAL AND THE "QUEEN AND CRESCENT."

"But man, proud man,
Drest in a little brief authority,
Most ignorant of what he's most assured,
His glassy essence, like an angry ape,
Plays such fantastic tricks before high heaven
As make the angels weep."

We have received a letter from a valued member, at the request of the railroad, deprecating the exposure of the methods of SUPERINTENDENT STEVENS in dealing with the members of the JOURNAL party at Cincinnati in a recent issue, and offering as an excuse that there was an agreement to deliver to the Queen and Crescent some six sleeping-car loads of people from the "Big Four" on the JOURNAL Special train. We were not responsible for opposition parties, and there was no such agreement, the JOURNAL simply urged as many as possible to go that way, and urged those who wished to join the Special elsewhere than at Chicago to join at Cincinnati and Indianapolis. There were therefore a sufficient number with those in waiting at Cincinnati, to make up a greater number than we had anticipated. We had made no definite promise. Now the facts are as stated in a previous issue, that MR. STEVENS compelled us to await the

arrival of the thirty-three persons who were with DRS. MOYER and WHITMORE of MR. G. S. DAVIS' *Medicine* party. That party was about four hours late, and the only possible reason why we were kept waiting was to save the expense of a special engine to haul them to Chattanooga; they were not going to Atlanta on our train, but were on an entirely different excursion route, intending to remain the next day at Chattanooga, and whatever may be said in extenuation, MR. STEVENS held us supperless in Cincinnati, and the time lost then made us late into Chattanooga, where our first stop was made for breakfast at 10:30 A.M., that is to say, from dinner at 3 P.M. Sunday until 10:30 A.M. Monday. All these things were explained to the great potentate, but he refused all requests and laughed in our faces, although nearly every male passenger made a personal appeal to him. That his phenomenal brutality should hurt the Queen and Crescent railroad is apparent, and if they are sorry for it they have a plain remedy, that is to repudiate MR. STEVENS and all his works, at the earliest possible date. It is possible that even the Queen and Crescent railroad may discover that it is not good railroad management to treat a hundred physicians and their families as a train load of immigrants. We are sincerely sorry for an otherwise excellent railroad and a passenger department, handicapped by such injudicious, indiscriminating, and inhumane officers. "We own this road" said MR. STEVENS; "this is *our* train, and we shall hold you until the Monon people arrive." That is the sum of MR. STEVENS' "concession," and so far as we are aware, nothing else was at any time contemplated by that mighty man, although our people had no more to do with the party in question than with any other party of excursionists in any other part of the Globe, except to wish them a safe and independent journey. If it hurt the Queen and Crescent people to have this JOURNAL tell the truth about their superintendent, we are sorry, but we must insist that a special train load of physicians traveling on any railroad shall be treated with the consideration and respect due their education, services and standing in the community, and not like a drove of cattle or a lot of immigrants traveling at immigrant rates. When this lesson shall have been thoroughly learned by certain railroad "magnates," the episode of MR. STEVENS will have had a useful outcome.

ASSOCIATION NEWS.

AMERICAN MEDICAL ASSOCIATION.

ADDRESS OF WELCOME ON BEHALF OF THE LOCAL MEDICAL PROFESSION.

BY FRANK M. RIDLEY, M.D., OF LA GRANGE, GA.

Mr. President and Gentlemen of the American Medical Association:—I would confess that I am profoundly sensible of the distinction conferred upon me by my professional brethren which places me here. Aside from an apprehension of my

A GEORGIA BARBECUE.

fitness to properly perform the task, it would be a labor of love to extend to you their greetings.

Such a welcome comes not alone from this fair city, which is the pride and marvel of us all, but from the great heart of this great commonwealth, stretching as it does from the sunlit summit of Lookout to where the crested billows break upon the white sands of our coast.

Founded in the wisdom and generosity of Oglethorpe, it was the youngest and feeblest of the old thirteen original colonies who by their conjoined efforts threw off the yoke of British domination on the plains of Yorktown. Not only so, but by their pronouncement sent forth from Independence Hall they, like the Veiled Prophet of Khorassan, "shouted freedom to the world," and thus started that great political movement which means "universal emancipation" and which to-day, it may be, is thundering at the gates of Moro Castle for the deliverance of liberty-seeking Cuba from the distress and ills of Spanish thralldom. In the meantime Georgia has grown to such proportions as to be recognized in no dubious sense as the Empire State of the South.

Here, then, gentlemen, in this capital of the Empire State, I bid you greeting; here under the shadow of Stone Mountain, that huge boulder upheaval from abysmal depths by some titanic force of pre-historic ages; here, in earshot of the "willow-fringed" Chattahoochee, described by our own Sidney Lanier as "springing in the hills of Habersham, and shouting through the valleys of Hall," as on it flows upon our western border 'mid banks of blooming flowers and springing ferns on its "eternal journey" to the Mexic sea.

Then, gentlemen, I bespeak the sentiment not only of my profession but of my State, when I say we rejoice at the gathering in our midst of this distinguished body of medical savants coming, as you do, from no pent-up Utica, but every part of this great nation, "from the slopes of the sea that sleeps, to the banks of the sea that's wild," from all sections of this boundless continent, composed of two score and more sovereign States, "distinct as the billows, one as the sea." We recall your former convocation in our midst, we miss the faces of those who, having served their day and generation, have passed to a higher state of existence, and to-day, "they rule our spirits from their urns."

In the meantime our profession has grown apace in all its branches. I do not exaggerate when I say that from the golden age of Pericles, when Hippocrates wrestled with that fearful plague which almost decimated Athens, until the days of Benjamin Rush, when the mercurial and the lancet constituted the chief armament of our materia medica, there was less advancement in the science of medicine than for the past half century; what the progress of another decade will be, the wisest of our number is unable to predict.

Organization with its concomitant influences has enhanced our achievements. The special work of individuals upon special lines has perhaps contributed more than aught else to an advancement and accomplishment. What political economists since the days of Adam Smith have designated as the "division of labor," has contributed more than aught else to the advancement of mechanical arts. Indeed, the steam engine would never have materialized but for the conjoined and con-

A GEORGIA BARBECUE.

secentive efforts of Watt and Stephenson; the cotton gin of Bull and Whitney, the spinning wheel of Arkwright, the ocean steamship would never have been perfected but for this "division of labor." What is said of the mechanical holds true of the higher arts. When Galvani touched, with a wire connecting a zinc and a copper plate, the muscles of a dead frog in his laboratory at Bologna, and caused it to leap like a thing of life, he instituted a new science. Thus by a special and individual study, Jenner discovered the vaccine virus, and by it curtailed the ravages of a dread disease and robbed it of its terrors. Koch discovered the bacillus which has destroyed so many useful lives, wrecked so many happy homes, and "hangs still like a pall" over humanity.

Pasteur has thus been able to counteract the subtle venom of the rabid dog. Lister has discovered antiseptics and thus almost revolutionized surgery, and our own Crawford Long discovered an anesthetic which has made the capital operations of surgery painless to the sufferer. Marion Sims applied the silver suture and thus instituted a new era in gynecology. Indeed, gentlemen, time would not avail me to mention one-tenth of the discoveries and applications of specialists in special lines which have given to medicine and to surgery the certitude of the exact sciences.

You, gentlemen, have come to further advance in your special sections the principles which these pioneers promulgated, and "they builded wiser than they knew." In behalf, then, of my profession I bid you greeting. Here, on this typical southern May day, beneath as lovely a sky as ever blessed the vision of the Mantuan bard, in a veritable atmosphere of hospitality, as bright as our sunshine, and as "sweet as the breath of the roses which bloom in our wildwood," I bid you welcome, thrice welcome, to this happy, prosperous, proud old commonwealth.

ADDRESS OF WELCOME ON BEHALF OF THE CITIZENS OF ATLANTA.

BY HON. JOHN TEMPLE GRAVES, OF ROME, GA.

Ladies and Gentlemen: You have just listened to an eloquent address from my friend Dr. Ridley, who has welcomed you to this beautiful city of Atlanta. The medical profession of Georgia is very fortunate in having a man so eloquent and versatile as Dr. Ridley. I congratulate myself upon the fact that I was born in the same year, attended the same college, although Dr. Ridley is some twenty years older than myself. (Laughter.) While I have enjoyed the rich and mellow eloquence of Dr. Ridley I have also enjoyed no less the benediction of the distinguished chaplain.

Beyond the ascription of praise to the Divine Power, which is always appropriate, it seems to me that the assembling together of a thousand doctors should be the occasion of prayer and profound concern to all classes of people. While the reverend and distinguished gentleman did not mention it specifically in his prayer, I think in his spoken aspiration to the hereafter he voiced the silent longing of this vast audience for a resting place in some better country where the doctors cease from troubling and the lancet is at rest. (Laughter and applause.)

Dr. Ridley has spoken the professional welcome of the city and the State. I speak for the helpless multitude—the outsiders—your victims, who languish under your lancets and are riddled by your horrid pills. I thank heaven that we have corralled you at last within the prison of our hospitality. You are harmless here. The geographic limit of your licenses has expired and the city is safe. If we should remove the legal

ban, if we should turn loose a thousand doctors on this helpless town, if we should add to the eager skill of our own professionals, the expert genius of this great convention, there is not a "liver" in Atlanta that would be safe to-night.

Atlanta is proud beyond expression of her brilliant galaxy of physicians. We support 200 doctors in this happy town, maintain them in the most lavish splendor and the most indolent leisure. There is nothing here for them to do. In the elixir of this incomparable air, and under the blue of these cloudless skies there is never an ailment that an old woman's nostrums wouldn't cure.

In the very desperation of their idleness, our physicians have been forced to forage. In the poverty of actual causes they have reached down into the sacred recesses of the human abdomen and dragged to the unwilling light a useless, obscure and infamous "appendix" on which to exercise their leisure and vindicate their skill. When the yellow scourge visited our southern coasts, this city of salubrity opened wide its arms to stricken refugees, and Westmoreland I., the distinguished father of the brilliant son radiant, with confidence in this higher air threw open his office to every suspicious case, and after ministering to their earlier symptoms drew down the drapery of his couch about him and lay down beside them in placid safety to pleasant dreams.

Our doctors here are almost without exception millionaires. They practice only on the stranger within our gates. They live in stately mansions, drive in splendid carriages and spend their time in thumping the soundest of "livers," and in feeling the steadiest pulses that ever beat in unison with the hope and progress of the healthiest and bravest city in the South.

There is not in all the world a better place for a doctor's holiday. Here you may lie down in peace to pleasant slumbers, and not a wave of trouble roll across your peaceful breasts.

But let me say in serious measure, that the city for which I speak is set in its very shape and structure to the end of hospitality. Its four great thoroughfares point the compass. Within their wide and generous angles they sweep all sections of the Republic. In their steady growth from center to suburb they have conspicuously or unconsciously assumed the shape of four extended arms, and these arms are now and always have been wide stretched in welcome to the world.

Atlanta is nature's city of conventions, framed for hospitality by its parts, its purpose and its generous soul. And the year behind us has been rich in accepted opportunity. Within the last two months of 1895 we banqueted around our social boards the press associations of twenty-six States, the governors and their State-house officers of twenty States, the mayors and municipal governments of the fifty representative cities of America. Around the hospitable mahogany of this new capital of the South that has risen like a phoenix from the ashes of the old, friendships have been formed, and sentiments of fellowship have been pledged that will be redeemed in the fulness of fraternity with which we shall march with locked arms through the stately stretches of our common and glorious future.

We make a new bond with this great convention. In the long visit of conventions which have met within our gates, not one has had a heartier welcome than we give to you. In war or peace, in sickness or in health, your great profession has been the healing and the solace of the world. In all this stately city, and in all this sovereign State, there is no home into which in some hour of gloom and sadness the physician has not come like incarnate comfort to the heart of grief. And in the flush and glow of rosy health it is a poor heart which does not in memory go backward from the sunshine to the somber shadows through which you moved in healing, like the benediction of the Lord. Next to the ministers of Almighty God, and linked in holy union with their blessed work, we

hold here the mission and the record of your service to mankind. And with all our hearts we give you greeting.

No other assembly could be more grateful to the heart and judgment of Atlanta. No greeting given to commercial convocations, no demonstration over literary lions, no blare and stir of bugles over gathered politicians shall vie in sincerity with the heartfelt greeting which we give to you.

Turn your stethoscopes upon us: level your heartsopes, your brainsopes, try us with the Roentgen rays of all intuitions, and you will find that Atlanta, city of conventions, abating no jot or tittle of the sincerity of any past profession, has held in her heart her last and most loving welcome for the doctors of America.

SOCIETY NEWS.

International Congress of Dermatology and Syphilography.—This Congress will be held in London this year, August 4 to 8. Eight subjects are announced for discussion as follows: Prurigo, keratosis, syphilitic reinfection, relations between tuberculosis and cutaneous troubles, duration of the contagious period of syphilis, trichophytosis, polymorphous erythema and malignant syphilis.

Indiana State Medical Society.—The forty-seventh annual meeting of this Society will be held at Fort Wayne, Thursday and Friday, May 28 and 29, 1896. The approaching meeting promises to be the best in the history of the Society and an unusually large attendance is expected, and it is particularly desired that the members not only make every possible effort to be present throughout the entire meeting, but that they bring their families with them and put in two days of profitable enjoyment. Every regular physician in the city of Fort Wayne is a committee of one to see that visiting members receive such treatment as may be expected from a progressive, enterprising and hospitable fraternity. Railroad rates of a fare and one-third are granted on all Indiana railroads, on the certificate plan, provided at least one hundred members avail themselves of these rates.

National Association of Railway Surgeons.—This Association, after one of the most important conventions in its history, adjourned *sine die* May 1 at 2 o'clock. The sessions were characterized by hard labor and diligent application to the important business in hand. The Convention was opened April 29 by Dr. W. B. Outten, Chairman of the local Committee of Arrangements. Health Commissioner Starkloff welcomed the visiting delegates to St. Louis in a brief address, in which he paid a glowing tribute to Pasteur, Lister and others who have helped to make a new science of surgery. Dr. F. G. Lutz replied in behalf of the visitors, and President J. B. Murphy then delivered his annual address. The latter reviewed the history of railway surgery from the time when round-houses were the hospitals and piles of ties the operating tables. The following papers were presented: The first was by Dr. T. H. Briggs, of Battle Creek, Mich., on "Surgical Treatment of Injuries of Spinal Cord and Column." The discussion was participated in by Drs. Outten, Hart and Jackson and President Murphy. Dr. S. R. Wooster read a paper on "Rupture of the Bladder with No Evidence of External Injury." The third paper was by Dr. Cassius D. Westcott, of Chicago, on "Traumatism of Eye-ball." Dr. Emmett Welsh, the Secretary, read a paper on "Color Blindness;" Dr. A. Alt, of St. Louis, read one on the "Tumor of the Lachrymal Gland," and Dr. James Moores Ball read an essay on "Eye Symptoms of Brain Tumor."

At the second day's session papers were read by Drs. E. R. Lewis, of Kansas City; J. H. Dixon, of Springfield, Ill.; J. B. Murphy, Chicago; A. H. Levings, Milwaukee; J. J. Buchanan, Pittsburg; George W. Crilly, Cleveland; John B. Deaver, Philadelphia; Harold N. Moyer, Chicago; Thomas H. Manley, New York, and John H. Punton, Kansas City. The surgeons were invited to Alexian Brothers' Hospital in the afternoon to a clinic with Roentgen ray features.

Dr. Emory Lanphear, of St. Louis, read a paper on "Why Railroad Surgeons Should Not Try to Practice Aseptic Surgery," which was virtually a reply to Dr. W. B. Outten's paper,

read before the Convention Thursday. Dr. J. A. Fulton, of Kansas City, also read a paper on "Inflammation of Bones." This closed the business of the Convention and an adjournment *sine die* was taken.

The new officers elected were: Frank J. Lutz, of St. Louis, President; Dr. Cassius D. Westcott, of Chicago, Secretary; Dr. E. R. Lewis, of Kansas City, Mo., Treasurer. The Vice-Presidents elected were Dr. W. R. Hamilton, of Pittsburg, Pa.; Dr. J. H. Letcher, Henderson, Ky.; Dr. Eddy, of Utica, N. Y.; Dr. Hutchinson, of Montreal; Dr. A. C. Wedge, of Albert Lea, Minn.; Dr. Goode, of Macon, Ga., and Dr. Lee, of Omaha, Neb.

The Executive Committee consists of Dr. Albert I. Bouffleur, of Chicago; Dr. J. N. Jackson, Kansas City; Dr. James A. Duncan, Toledo; Dr. J. B. Murphy, Chicago; Dr. W. S. Thorne, Toledo; Dr. W. D. Middleton, Davenport, Iowa; Dr. J. A. Barr, McKee's Rock, Pa.

Proceedings of the Congress of the French Association for the Advancement of Science.—This association of savants met at Tunis, April 1-5. (Reported in *Bulletin Médical* April 5, 8 and 22.) In the Section on Medicine Hanot presented a careful study of "Cancer of the Ampulla of Vater," reviewing the eleven cases on record, with one new one. The clinical picture comprises chronic, progressive, apyretic icterus, with discoloration of the feces, medium hypertrophy of the liver, gall bladder and spleen, without severe pains, increasing emaciation, and death in five to nine months. Histologic examination shows the cancer to be a cylindric-celled epithelioma. In Hanot's case, which had a much longer duration than the rest, there was constant leucocytosis, which favored the supposition of a cancer, while the absence of urobilinuria negated the idea of any important hepatic lesion. The icterus gradually subsided; the necropsy showed that the obstacle to the flow of bile had not been removed, but that the bile had undergone the transformation which Hanot calls pigmentary acholia. The patient's health had always been robust until two years previously, when he had entered the Bichat hospital for a fractured malleolus, and he stated that his serious trouble dated from that time, the emaciation, icterus, etc. A vegetating, non-ulcerous mass was found at the necropsy, about the size and shape of a chestnut, adhering to the mucous membrane of the ampulla of Vater, in which it had developed, projecting downward into the intestine which it did not obstruct at all, although it closed the pancreatic and common bile duct, entering it at this point. Considering the relative frequency of other official cancers, Hanot is surprised at the rarity of this kind, and he queries whether surgical intervention might not be successful with such a limited growth. Bard continued the subject by comparing this form with cancer of the pancreas, which it clinically resembles, while cancer of the duodenum partakes of the character of cancer of the stomach and of the pylorus, with a different set of symptoms due to obstruction of the alimentary canal. He considered cancer of the ampulla of Vater to be of pancreatic origin, starting in the excretory duct and characterized by a relatively slow development, by the absence of generalization and the variability of the icterus.

Cartaz described two forms of "Facial Paralysis from Otitis following La Grippe," one where the paralysis ceased at once with puncture of the tympanum, releasing the serous fluid that compressed the nerve, producing the paralysis; and a second form where the paralysis persisted, showing that the inflammation had extended to the nerve.

Bard has always found in cases of cancer of the pancreas with glycosuria, that there was a secondary cirrhosis of the pancreas accompanied by secondary cirrhosis of the liver due to the same cause. Glycosuria, therefore, while it does not prove the existence of a pancreatic cancer, is an aid to diagnosis when it accompanies an icterus from obstruction. It shows that this obstruction is in the pancreatic as well as in the biliary ducts, and therefore favors the assumption of a cancer of the head of the pancreas rather than a biliary obstruction from some other cause.

Voisin reported the case of a woman affected with melancholia, hallucinations of persecution, aphasia, word blindness, agraphia and hemiopia, following a severe attack of pleuropneumonia, which he had completely cured by hypnotic suggestion. He also carried her afterward through childbirth without her having the slightest knowledge of any of the events of her accouchement.

Double syphilitic gummy tumor in the spinal cord, producing complete paraplegia of the lower limbs and trunk, and the symptoms of syringomyelia, with absence of knee jerk and foot clonus, continual incontinence of urine, paralysis of the rectum and unequal movement of the pupils, was the

clinical picture of a case described by Hanot and Meunier, which terminated fatally in five days. They made 198 sections of the spinal cord, as this is such a rare disease, that they only knew of eight cases on record, with microscopic researches in three. They first established the fact that the tumors were not tuberculous, and then proceeded to explain the startling suddenness and violence of the attack by showing that the paraplegia had been menacing for some time, evidently, the pyramid so compressed by the tumors situated each side of the spinal cord, at the level of the first left dorsal and the second right, that it only required some slight arterial thrombosis to upset the balance and produce the ictus and the above symptoms then proceeded evenly on both sides. The syringomyelia and the peculiar zones of anesthetic and hyperesthetic skin, they explain by the fact that the sensory conductors of heat, pain, etc., from different zones of the body, do not follow the same path in the spinal cord. While the former enter the brain through the funiculus gracilis, the others (heat and pain) form part of the gray matter itself. The former, therefore, entered a portion of the spinal cord which was intact, passed into the funiculus gracilis, which was not affected and skipping the seat of the lesions, passed on into the brain. Those which started in the upper part of the trunk, were right in the midst of the lesion. To this is due the difference in the sensations in different zones of the body. The connection between the sensory and motor disturbances corresponded in this case with Brown-Séquard's "spinal hemiparaplegia with crossed hemianesthesia," only with the peculiarity that it was bilateral.

CORRESPONDENCE.

Typhoid Fever; Another Witness.

BLAKESBURG, IOWA, May 16, 1896.

To the Editor:—Prove all things; hold fast that which is good.

Whilst the mortality from typhoid fever continues to run so appallingly high, the true physician should never tire of reading any and all articles within his reach that will tend to throw light upon the subject, or aid him in reducing that mortality. The great number of deaths still reported from the ravages of typhoid fever is a stigma upon the whole medical fraternity—is truly mortifying in the extreme.

It may be true that some of our brethren jump at conclusions too hastily—are to ready to accept new theories and adopt new remedies; yet it is also true that many are too slow to admit that "there is anything new under the sun." They manifest a stoical indifference—even a dogmatic sarcasm and a stubborn skepticism, regarding all new discoveries, even when they are launched upon us by one whom they regard as eminently orthodox.

While the silent cities of the dead continue to grow so rapidly, the true physician has no moral right to show this stolid indifference. It is indeed not so surprising that the laity become skeptical, that they in a great measure lose confidence in all doctors and readily take to patent nostrums, faith-cures and Christian science.

But I wish brevity to be one merit of this letter, and laying aside all theories and all discussions upon the etiology and pathology of typhoid fever, I wish to add my testimony on the therapeutics of the disease.

What the laity ask of us is to cure the disease, to save their loved ones from an untimely grave. Must we turn a deaf ear to their cry? Do we not owe to the world something better and more promising than the old régime in the management of this dreaded disease?

As regards typhoid fever, I believe the problem has been solved. I do now believe we can cry out: Eureka! I am naturally somewhat skeptical myself; am slow in accepting new ideas, but I have always been in constant search after demonstrated facts. I do not now wish to be over-enthusiastic, but I most sincerely believe that the name of Dr. J. Eliot Woodbridge should, and will be handed down to coming

generations, on the golden pages of history, along with those of Jenner and Pasteur.

After having read the reports of scores of physicians in the *AMERICAN MEDICAL ASSOCIATION JOURNAL* and elsewhere, and after a personal experience in over seventy-five cases, I am convinced that the treatment now known as Dr. Woodbridge's antiseptic treatment of typhoid fever, is as surely prophylactic and curative, as is quinin an antiperiodic; that it will greatly modify the severity of the disease, even in the later stages, and will *abort typhoid fever*, if begun early and rigorously carried out.

My experience with the Woodbridge treatment has been most gratifying. To be able to carry my patient through, even when not seen in the first week, in from fourteen to twenty-one days, with a temperature seldom above 102.2, without delirium, with the mental faculties clear, with but little tympanites, without hemorrhage from the bowels, with a liberal allowance of food, with no grave complications and with rapid convalescence, is certainly very gratifying.

It is needless, here, to give the Woodbridge formulæ in detail. The readers of the *JOURNAL* have them. I only urge all who have not tested them, to do so and be convinced. First of all, be sure that you have *pure* medicines and have them compounded under your own supervision, and then have the attendants follow your instructions most implicitly.

I doubt not that Dr. Woodbridge can and will, in the near future, simplify his formula No. 1. I will here state that in a few cases, I did not find the mixture No. 2 well borne. To these cases I gave guaiacol carbonate alone, omitting the eucalyptol. Guaiacol carbonate is well borne by the most delicate stomach and is more easily administered to children than the liquid. I advise no auxiliary treatment, save the sponge bath, cleanliness and plenty of fresh air, with an occasional diuretic if necessary, and a dose of bromidia at night if the patient does not rest well.

Just here I would caution against the use of any of the coal tar products in typhoid fever, no matter how high the temperature runs. Shun them as you would an infernal machine.

Yours respectfully, C. N. UDELL, M.D.

Medical Directors of Life Insurance.

DENVER, COLO., May 12, 1896.

To the Editor:—In our *JOURNAL* of April 18, mention is made of the annual meeting at Richmond of the "Association of Life Insurance Medical Directors," on April 30 and May 1. Can you inform me who and where are the officers, secretary especially, of the Association?

S. T. McDERMITH, M.D.

PUBLIC HEALTH.

Queensland for Consumptives.—The *Australian Medical Gazette* states that tuberculosis is almost unknown in the Queensland-born population. It also says of Australia at large that phthisis is decreasing in prevalence.

Connecticut Candy not to be Adulterated.—Any person who shall adulterate candy with terra alba, barytes, talc, or any other mineral substance, or with poisonous colors or flavors, or knowingly sell or offer for sale, candy so adulterated, it was enacted in Connecticut in 1895, shall be punished by a fine of not more than \$100.

To Prevent Blindness in Connecticut.—Should one or both eyes of an infant become inflamed, or swollen, or reddened at any time within two weeks after its birth, it shall be the duty, under penalty, according to a law passed in Connecticut in 1895, of the midwife, nurse, or attendant having charge of such infant, to report in writing within six hours, to the health offi-

cer or board of health of the city, town or borough in which the parents of the infant reside, the fact that such inflammation, or swelling, or redness of the eyes exists.

Commissioners of Pharmacy in Connecticut.—Section 3118 of the general statutes of Connecticut was amended in 1895 by striking out in line two thereof the words "one reputable physician and two" and inserting in lieu thereof the words "three reputable," so that the section now reads: "There shall be three commissioners of pharmacy, consisting of three reputable pharmacists, to be selected by the governor from six persons to be annually nominated to him by the Connecticut Pharmaceutical Association."

Antitoxin of Alcoholism.—M. Toulouse has conceived the idea of finding an antitoxin for alcoholism. He administered to a dog 40 grams of ethyl alcohol daily during a week. He then took some serum from the animal, and injected 24 grams in three doses into a patient suffering from delirium tremens. The next day the temperature was lowered, there was less fever, and the patient became rational. M. Toulouse is following out his research to ascertain if the serum acted as an anti-alcoholic serum or only as a non-specific serum.

To Prevent Spread of Hydrophobia in Florida.—Sections 769 and 772 of the Revised Statutes of the State of Florida were amended in 1895, adding hydrophobia to the list previously composed only of yellow fever, smallpox and cholera, to be quarantined against (though it is provided that in cases of hydrophobia the State health may be represented by any authorized agent or agents of the State board of health in investigating with regard to same), and giving to the State board of health power to make, promulgate and enforce such rules and regulations as may be necessary to prevent the importation and spread of hydrophobia.

Sanitary Control of Milk Supplies.—In line with the now accepted dictum that the dairy farm is the chief source where milk becomes infected, Health Commissioner Emery has appointed a Dairy Inspector, whose duty will be to investigate the sources of the entire milk supply of Brooklyn. He is charged with the duty of examining the cow stables, the number of animals therein, their sanitary condition, the water they drink, and the drainage of the stables. If, in his opinion, any feature of any of the dairies is unsatisfactory, he has power to prohibit the sale in Brooklyn of milk from that establishment.

California Coroner to have Stenographer.—It was made lawful, by act of 1895, for the coroner of every county, or city and county, in California, having 100,000 or more inhabitants, to select and appoint an official stenographic reporter, at a salary of \$150 a month. It is made the duty of such reporter to attend all inquests held by the coroner and report in shorthand all testimony of witnesses, and all proceedings of such inquests, and to transcribe the same into legible longhand and furnish two typewritten copies thereof, to certify the same, and file one of the copies with the coroner, and the other with the clerk of said county or city and county, and also file with such clerk the original shorthand notes.

Health Officer can not Enjoin Maintenance of Hospital.—The supreme court of Wisconsin decided, March 10, 1896, in the case of *Buckstaff v. City of Oshkosh*, that there is no power, express or implied, under the Wisconsin statute directing town health officers "to take such measures for the prevention, suppression and control of contagious disease as may be needful and proper, subject to the approval of the board of health," authorizing the health officer, either in his own name or in the name of the board of health, to enjoin the maintenance of an isolation hospital for contagious diseases near the town. But, whether the action lies, or, if so, whether it can be instituted without authority conferred by the electors, the court does not undertake, in this case, to decide.

Nuisances Injurious to Health in Florida.—An act was passed in Florida in 1895 defining at considerable length and declaring what shall be deemed nuisances to health, and to provide for the removal thereof and punishment therefor. It makes it the duty of the State health officer, upon the request of the proper authorities, or of any three responsible resident citizens, or whenever it may seem necessary to the president of the State board of health, or to the State health officer himself, to investigate the sanitary condition of any city, town or place in the State: and if upon examination, the State officer shall ascertain the existence of any sanitary nuisance as defined in this act, it shall be his duty to serve notice upon the proper party or parties to remove or abate the nuisance, or if necessary, to proceed to remove or abate the nuisance.

Curiosities of "Quarantine."—A bill before Parliament to abolish the last trace of quarantine in England induces *The Hospital* to call attention to the fact that the plague had disappeared from England for more than thirty years before the practice of quarantine against it was definitely established by Act of Parliament in 1710, and that, with the exception of yellow fever, plague still remains the one disease against which the provisions of the Quarantine Act are still in force. While the sanitary administration has been dealing with every other kind of malady, the responsibility of taking precautions against these two diseases continued, and still continues, to devolve upon the Imperial Government, which has neither quarantine establishments nor isolation hospitals for the purpose. So far as plague is concerned this does not matter, but yellow fever is epidemic in ports with which England has considerable trade, and it was imported into Swansea in 1865, when it caused a considerable mortality. *The Hospital* thinks it high time, therefore, that its control should be handed over to the sanitary authorities.

Dangerous Athletic Exhibitions should be Restricted.—The *Boston Medical and Surgical Journal* asks a very pertinent and searching question: "Are these hazardous trapeze performances allowable in civilized communities?" The recent accident to a trapeze performer in Boston, in which a fall from the trapeze produced a fracture of a cervical vertebra, calls renewed attention to the dangers of such exhibition and emphasizes the question: "Are they worth while?" The ratio of the interest to the risk we will not undertake to estimate, but this much, at least, can be said, that these accidents result, as in this case, from the necessity which the performers are under of meeting their engagements often when they are not in the best physical condition. In New York, the "Human Arrow," as she is called in the play-bill, is in daily jeopardy from the chance that an accidental discharge of her mammoth crossbow may cause her to fall a distance of thirty feet. The other night the bow-string caught her at the back of her head and knocked her senseless, but her brother was able to reach and rescue her just at the moment of falling. And yet these cunningly devised enormities have no sanction of law for their prevention.

The Buffalo Medical and Surgical Journal.—The exclusive management of the June issue of that periodical has been entrusted to the medical ladies of that city. There will doubtless be a great demand for that issue from all parts of the country. If the time were not so short, we would like to submit for their consideration the following proposition, taken from the *Medical News*: One of the metropolitan papers has been devoting attention to the microscopic examination of the street dirt found adhering to the dress skirt of a lady after an afternoon's shopping in New York. It reports to have obtained from one skirt, besides innumerable innocuous and unclassified organisms, the germs of fever, influenza, anthrax, and diphtheria. This means of transferring virulent matter from the streets to the house is, without doubt, a frequent one, and very naturally suggests two very important sanitary reforms, to-wit:

Cleaner thoroughfares and shorter skirts. The sense of supreme security which the new woman feels in this particular must be regarded as some compensation for her more or less complete self-denial of the ordinary female garments.

Departments of Health Have Oversight of Shop-women.—A bill to protect the lives and health of deserving and industrious young women and to give them relief from much suffering has become a law in New York State. This bill fixes the hours for women and children in mercantile establishments at sixty hours per week, or an average of ten hours per day, excluding Sunday. Thus, if such employees are kept two or three hours longer at work on Saturday than on any other day in the week, the extra time must be made up by deduction from the labor of other days. The bill further provides that chairs shall be provided for women who are now kept standing for hours without rest, a practice productive of many serious ailments. It is also made the duty of the Board of Health to examine cellars and toilet rooms where women and children are employed and to give certificates as to their sanitary condition. A specially onerous duty has been devolved on local boards of health in a requirement for the medical examination of all shop-girls under sixteen years of age, the keeping of records of a detailed character and the issue of certificates to children requiring them and undergoing the prescribed examination.

A Timely Rebuke.—Under the laws and ordinances—not of New York city only, which is the *locale* of the following words of protest from a contemporary (*American Medico-Surgical Bulletin*, April 25)—professional men are obliged to report to boards of health the presence of diseases of an infectious nature occurring in their practice. This duty is cheerfully conformed with, since it is recognized as requisite in order to enable statistic data to be properly kept, and also because it is important that contagion should be prevented and the spread of epidemics be avoided. This duty, furthermore, the professional man performs without remuneration, considering that it is something which he as a citizen owes to the commonwealth. Boards of health in recent times have, in every possible way, endeavored to devise means for making the matter of reports as little a tax as possible on the time of the busy practitioner. Neither the law, however, nor the dictum of any board of health justifies its employees figuring in the role of either attending physician or consultant. The strict limitation of the duties of the inspector is to certify that there exists a case of contagious disease in the household whence the report emanated, and this is all. If he should find that the diagnosis was an erroneous one, it is not within his province to so state to the family or the patient, thus inevitably casting disrepute on the diagnostic ability of his professional brother. Inspectors from the board of health can neither figure as attending nor as consulting physicians unless so requested to act by the physician in charge. In the event of the meddlesomeness of an inspector leading to serious complication the *Bulletin* questions if the board of health, since in the eye of the law it is held responsible for the acts of its agents, does not lay itself open to suit for damages. All this is apropos of alleged flagrant instances of meddlesomeness and officiousness on the part of employees of the New York Health Department. But are there not others, and nearer the publication office of the *JOURNAL* than New York? There is ground for answer in the affirmation and this outspoken rebuke should be heeded by these also.

Repression of Bovine Tuberculosis in Connecticut.—The *Yale Medical Journal*, March, has the following editorial estimate of the value of the anti-tuberculosis legislation of 1895, in Connecticut:

"A law was enacted by the legislature of this State about one year ago, the aim of which was to eradicate bovine tuberculosis. Prior to the enactment of this law there was much

discussion upon it and strong efforts were made by the agricultural portion of the State to secure its defeat. The law provides for the appointment of three commissioners whose duty it is to inspect the cattle of the State for tuberculosis, using tuberculin as a diagnostic agent when so permitted by the owners of cattle, and to destroy all animals found affected with the disease. The law has now been in operation about twelve months and it has been found that quite a large per cent. of cattle are affected with tuberculosis. As it has been repeatedly proven that bovine tuberculosis is directly transmissible to man from meat, milk, or other ways, the importance of carrying out the above law becomes apparent to the general public and especially to the medical profession. The law can work no real hardship to the owners of cattle as it provides that the commissioners shall assess all animals at their market value before the tuberculin test is made. We hope that the law may be allowed to remain upon the statute books and so enforced that in the years to come a case of tuberculosis among the cattle in this State will be hard to find. As the principal source of the transmission of the tubercle bacilli from animals to man is through milk, the importance of the recent suggestion that a sanitary milk laboratory be established in every city, can not be overestimated. This plan is not entirely new, having been in operation for a considerable time in some of the larger cities of the country and meeting with very notable success in Boston, Mass. The object of an institution of this kind is, first, to provide pure, wholesome milk for general consumption; second, to provide pure milk, scientifically modified according to the directions of a physician to meet the needs of any particular case. Such establishments would be a great benefit to a large proportion of the population of this State, or any other which might adopt this system, and the danger of the transmission of the tubercle bacilli through milk would be reduced to a minimum. Although the danger of the disease being transmitted from animals to man is considerable, we know that the greatest danger is from the dried sputa of tuberculous patients and we would urge physicians to appeal to the better natures of their patients and warn them of the evils which may result from promiscuous expectoration."

Typhoid Fever in Indiana.—On account of the high rate of mortality from typhoid fever the State Board of Health of Indiana has issued a circular order to health authorities, attending physicians and heads of families relative to its prevention and suppression. The order went into effect May 1. It states the total number of cases during the past year in the state as 8,100, number of deaths 2,400. After reciting the methods by which typhoid fever is propagated it defines the duties of the physicians as follows:

1. Promptly report the case to the city or county health officer. This is a *moral, social and legal duty*. The county officer will report to this Board, and then analysis of water and other sanitary work can be undertaken.
2. If possible, have the patient placed in a room apart from the rest of the family, preferably on the top floor, and nursed as far as possible by one or two persons. Sometimes nurses make bread or prepare other food, with hands contaminated by caring for the patient. This leads to other cases in the family.
3. The dishes, knives, forks, spoons, underclothing and other articles used by the patient, should not be used by any one else, and should not be removed from the room until they have been disinfected. This is done by placing them for an hour in a solution of carbolic acid (six ounces of the acid to one gallon of water) and then boiling them in water.
4. The manner of disposing of the discharges from the bowels is of the *utmost importance*. In the vessel receiving the discharge there should be a quantity of chlorid of lime, and after the discharge is received it should be covered by at least a pint of solution of chlorid of lime in the proportion of six ounces to a gallon of water. It should be allowed to stand for an hour, and be thoroughly mixed before emptying into the closet.
5. The hands of those caring for the sick, and the portions of the patient's body which have become soiled with discharges should be frequently disinfected with a carbolic solution. The carbolic solution above described can be diluted one-half or the purpose.

THE DUTY OF HEALTH OFFICERS.

1. Every case of typhoid fever must be reported by the physician to the county health officer. Any physician failing in his duty to himself and humanity will be presented.
2. Upon receipt of report of a case of typhoid the county health officer shall, without delay, in *conjunction with the*

attending physician, visit the patient and make a thorough investigation. A sanitary survey shall be made of the premises according to the "Sanitary Survey Blank for Typhoid," and said blank, when filled, shall be filed to make a record. Every effort must be made to discover the source of the disease. The incubation period of typhoid may be seven days, average is twelve to fourteen days: greatest, twenty-three days.

Ninety-five per cent. of all cases of typhoid proceed from drinking water. Therefore, a close investigation must be made of every well from which the patient may have drunk for seven to twenty days preceding the attack. If, in the judgment of the Health Officer, analysis is required, send a copy of the Sanitary Survey to this office and ask that *Instructions A* be returned to you. This circular gives detail instructions for the collection of samples of water for bacteriologic and chemie analysis. The work will be done without cost, but will only be done when absolutely needed, and when every requirement of this office has been fulfilled. By order of the State Board of Health.

D. C. RAMSEY, M.D., President.

J. N. HURTY, M.D., Secretary.

Health Reports.—The following health reports have been received in the office of the Supervising Surgeon-General Marine-Hospital Service:

SMALLPOX—UNITED STATES.

Alabama: Mobile County, May 11, 2 cases.
Florida: Pensacola, May 2 to 9, 2 cases.
Louisiana: New Orleans, April 20 to May 7, 29 cases, 7 deaths.
Michigan: Ionia, May 2 to 9, smallpox reported.
Tennessee: Memphis, May 9 to 16, 2 cases.

SMALLPOX—FOREIGN.

Bristol, April 25 to May 2, 3 cases.
Cairo, April 9 to 15, 1 death.
Callao, March 29 to April 12, 10 deaths.
Cienfuegos, May 3 to 10, 17 deaths.
Copenhagen, April 11 to 18, 2 cases.
Genoa, April 25 to May 2, 2 cases.
Guayaquil, April 17 to 24, 4 deaths.
Licata, April 18 to 25, 1 case.
London, April 25 to May 8, 5 deaths.
Madrid, April 21 to 28, 11 deaths.
Manchester, April 25 to May 2, 1 case.
Moscow, April 18 to 25, 1 death.
Odessa, April 18 to 25, 22 cases, 4 deaths.
Prague, April 18 to 25, 4 cases.
Rio de Janeiro, April 8 to 15, 8 cases.
St. Petersburg, April 18 to 25, 26 cases, 11 deaths.
Swansea, April 25 to May 2, 2 cases.
Trieste, April 11 to 18, 3 cases.
Tuxpan, April 19 to 26, 7 deaths.
Warsaw, April 11 to 18, 1 death.

CHOLERA.

Alexandria, April 8 to 15, 15 deaths; Dec. 29, 1895, to April 26, 1896, 130 cases, 115 deaths.
Shimane Ken, Japan, April 19, 1 case.

YELLOW FEVER.

Rio de Janeiro, April 11 to 18, 122 cases, 98 deaths.
Cuba: Santiago, April 25 to May 9, 5 deaths; Havana, May 1 to 7, 13 cases, 6 deaths.

NECROLOGY.

DR. JOHN STEWART, formerly of Tai-ho, China, and latterly of Glasgow, Scotland, died at the latter city, after undergoing an operation for the relief of hepatic abscess, being then in his 37th year. During ten years of his life he had been one of the most laborious of medical missionaries of northern China, where he had conducted a free dispensary which was often crowded from seven in the morning until far along in the day, and where thousands of patients passed through his hands every year. Dr. Stewart began his medical studies at Marshall College, Aberdeen. He came to America and soon obtained a post in a large manufactory in Philadelphia that required him to be on duty every night. For three or four years he occupied this position, attending Pennsylvania University during the day, where, at the end of that period, he gained his M.D. Returning to England, he applied to the C. I. M., and pending acceptance, attended special classes in the London hospitals. He

went to China in 1885, and 1888 came to the city of Kwei-hwacheng in the far north, and labored there for the past seven years.

HERMAN LOEWENTHAL, M.D., of New York City, who died April 21 at the private hospital of his friend Dr. Lange, was a graduate of the University of Berlin in 1860. He was born in Berlin sixty years ago. He had served as a surgeon in the Prussian army until 1863, when he came to this country and entered the United States service as assistant surgeon, being subsequently promoted surgeon with the rank of major. After serving in the hospital at City Point he was transferred to the General Hospital at Annapolis, where he remained until the close of the war, when he retired from the service and established himself in private practice in New York, where he was widely known as a specialist in the diseases of women. President Cleveland appointed him an examining physician in the Pension Bureau. Dr. Loewenthal was a prominent Mason and a member of the G. A. R. He leaves a widow and six children.

WILLIAM SHARP, M.D., of Rugby.—The *Medical Press and Circular* has the following obituary note regarding Dr. Sharp: "The death of Dr. William Sharp, of Rugby, who has just died in his ninety-first year at Llandudno, has reminded the world of the youthfulness of the natural science curriculum. Dr. Sharp settled originally in Bradford, where he succeeded his father and became senior physician to the Infirmary in 1837. He afterward removed to Rugby, and persuaded Dr. Tait to introduce natural science into the Rugby teaching. This was eventually done, on condition that Dr. Sharp would become the first teacher, under the title of 'Reader in Natural Philosophy.' Dr. Sharp came of a north country stock which had been famous for its scientific attainments, and Dr. Sharp himself was made Fellow of the Royal Society in 1840. His Degree of Medicine was that of Lambeth, formerly in the episcopal gift, but now in abeyance. With regard to the public school science appointment, the late Tom Hughes observed, 'If Tait had done nothing else at Rugby than appointing Sharp, not without difficulty, as Reader in Natural Philosophy, he would have deserved the gratitude of every Rugby man.'"

J. WEST ROOSEVELT, M.D.—The following tribute to the memory of Dr. Roosevelt has been feelingly voted by the directors of the New York Physicians' Mutual Aid Association:

"The directors of this association have heard with deep regret of the death of Dr. J. West Roosevelt, an honored member of the association. His learning, his probity and his manliness were qualities which endeared him to all with whom he came into association.

"They acknowledge with deep appreciation his generosity and kindness in bequeathing to the association the amount of his claim, \$1,000, as an addition to the permanent fund of the association, and feel that in no surer way could a benefaction be made, for all time, a blessing to the needy members of his profession in this State.

"It was ordered that the name of Dr. J. West Roosevelt be placed on the list of benefactors of the association, and that notice of this action be sent to the medical journals."

ISAIAH F. PRAY, M.D., of New York City, died April 23, aged 59 years. He was a native of Maine, an arts graduate at Dartmouth College, and an M.D. at the New York University in 1870 and 1874 respectively. He was a member of the Pathological and County Medical Societies. A widow survives him.

JACOB RAY, M.D., died suddenly at his home, No. 284 Ferry street, Newark, N. J., on May 7, aged 73 years, of paralysis. He was born in Württemberg, 1824. He was a surgeon in the Württemberg army in 1849, when the latter was sent to Baden to quell the revolution there. He again saw field service in 1895, in the war with Prussia. In 1890 he came to the United States and made his home permanently in Newark.

JAMES B. HARRIS, M.D., of Sag Harbor, N. Y., died April 17, of pneumonia. He was 36 years old, and a graduate of the

New York College of Physicians and Surgeons, a member of the class of 1882.

J. G. WILLIAMS, M.D., at Braddyville, Iowa, May 2, aged 66.—M. C. Heath, M.D. (Med. College of Fort Wayne, Ind., 1883), of pulmonary tuberculosis, at Cadillac, Mich., May 2, aged 38.—Frederick Dunning, M.D. (Jefferson Med. College, Philadelphia, 1892), at Easton, Md., May 9.

BOOK NOTICES.

Dame Fortune Smiled. The Doctor's Story. By WILLIS BARNES. Pp. 335. Boston: Arena Publishing Company, 1896. Chicago: A. C. McClurg & Co.

This is a very readable novelette, in which a well educated young German physician, while in Paris completing his studies, becomes acquainted with some wealthy Americans who induce him to settle in New York. They make his fortune and he cures them of nervous prostration by hypnotic suggestion. He marries a bright and well educated newspaper correspondent, and his charming clients build him a sanitarium and strive to outdo each other in making charitable largesses. This is an excellent study for your wealthy patients.

General Index to the Journal of the American Medical Association. Vols. I to XXIV. By WM. B. ATKINSON, M.D. 8vo, cl., pp. 360. Chicago: AMERICAN MEDICAL ASSOCIATION Press, 1896. Price \$1.25.

This index will be found very useful to all medical men. In case they do not have the bound volumes of our JOURNAL, the index will tell them what has appeared in its pages, and there are few places in the United States where some one has not preserved his JOURNAL. Libraries will find this index indispensable; it includes the names of author and subject, and is printed in clear type on excellent paper.

Gentlemen noticing errors or omissions in it are asked to kindly send the correction to the editor of the JOURNAL.

Some Prolegomena to a Philosophy of Medicine. By GILES F. GOLDSBOROUGH, M.D., President of the British Homeopathic Society, etc. London: John Bale & Sons. 1896. Cl., pp. 66.

This is an attempt on the part of an English "homeopathic" practitioner to lay the foundation of a philosophy of medicine which may be considered as a sort of composite photograph of all systems which now exist. We can see no very good reason why the title could not have been condensed from "Some Prolegomena" to the simpler and more familiar word "Introduction," which means essentially the same thing. There are several new terms introduced. Not only is there little to find fault with, but much to be commended. The book is handsomely in appearance.

MISCELLANY.

Queer Place to Have Them.—A chiropodist announces on his cards that he has had the honor of removing corns from several of the crowned heads of Europe.—*Printer's Ink.*

An Octogenarian.—Dr. Alonzo Garcelon, the President of the Board of Trustees, celebrated his eighty-third birthday at the recent meeting at Atlanta, on which occasion he was the recipient of the hearty congratulations of his colleagues in the Association.

Requests to New York Charitable Institutions.—Under the will of the late Leonard Friedman the Mt. Sinai Hospital gets a bequest of \$2,500, the Montefiore Home for Chronic Invalids \$1,500, and other Asylums and Homes about \$7,000 in different sums.

Rare Quadruplets.—It has been estimated that a case of quadruplets occurs but once in 350,000 to 400,000 births. But if the proportion were one in a million, or even a billion, there

would always be two persons who would regard the prodigality of nature as an act of unkindness.—*Medical Press*.

He Affirmed the Negative.—"Well, doctor, is there any thing the matter with my foot?" asked Jones. "My answer," replied the doctor, "is in the negative." He had taken up the new photography.—*Pick-Me-Up*.

"Idiotic" Acid.—"What acid do we get from iodine?" asked the medical professor. "We get a—usually get idiotic acid," yawned the student. "Have you been taking some?" quietly asked the professor.—*Medical News*.

Life's Problem Given Up.—"After all," asked a disciple of Diogenes, the great thinker, "what is life?" "That, sir," he replied, "is a riddle which, in the end, is given up by every body."

She Had Rather Be an Aquarium.—Fashionable Doctor: "My dear young lady, you are drinking unfiltered water which swarms with animal organisms. You should have it boiled; that will kill them." His patient: "Well, doctor, I think I'd sooner be an aquarium than a cemetery."—*Harpers Weekly*.

A New Bacillus in Milk.—Obermuller writes to the *Hygienische Rundschau*, No. 19, 1895, that he has been inoculating guinea pigs with ordinary milk from a supposed well-appointed establishment. Several of the animals died with typical tuberculosis and the rest gave evidence of a peculiar infection, produced by a special bacillus, hitherto unknown, which he will soon more fully describe. In another series of experiments 38 per cent. showed tuberculous infection and 30 per cent. wasted away.

Druggist Suffers for Illegibility of Handwriting on Prescription.—A Paris druggist has just been fined 500 francs for compounding a prescription, the signature of which had been purposely rendered illegible, as it did not proceed from a physician. The regulations are that the druggist must insist upon the signature of a physician to each prescription, and verify the existence of local physicians by consulting the directory if necessary.—*Journal de Médecine de Paris*, March 15.

California Female Insane to Have Attendant.—Section 2218 of the Political Code of California, relating to the commitment of insane persons, which provided that the insane person, together with the order of the judge and certificate of the physicians, must be delivered to the sheriff of the county, and by him must be delivered to the officer in charge of the insane asylum, was amended in 1895, by adding, "but no female insane person shall be taken to the asylum without the attendance of some other female, or some relation of such insane person."

Endemic Ulcers.—Juliano, of Bahia, Brazil, is studying the endemic ulcers known variously as the Biskra button, Burmah boil, Cochinchina ulcer, Alibert's endemic prophylitis, Larrey's ulcerous dermatosis, Sahara chancre and by other local names. He prefers to call it the endemic button of the tropics, and believes that it is caused by some microorganism, which he is now trying to discover. He finds it most frequently on the face or extremities, which shows that it is usually communicated by the bite of some insect. He has a careful study of it in the *Journal des Maladies Cut. et Syph.*, October, 1895.

Tarnier's Treatment of Postpartum Hemorrhages, described at the Congress of the Obstetrical Society of France, last month, is merely a tampon, if the hemorrhage proceeds from the neck of the womb, the vagina or the vulva. The important point is to locate the source. If it proceeds from the body of the uterus, it is a serious matter then, and he applies heat in the form of hot water, but first he clears out of the uterus every trace of clot, in spite of all protests, sometimes having to clear it two or three times. If there is the slightest fragment of a clot left, the uterus is liable not to contract. Tarnier advises the use of hot water as a preventive measure when there is a known

individual or family tendency to hemorrhages or uterine inertia. He has never lost a patient from a postpartum hemorrhage, and he gives no drugs except in very rare cases he follows the hot water with a hypodermic injection of ergotinin.—*Progrès Médical*, April 18.

Anecdote Regarding the Late Dr. E. R. Palmer, of Louisville University.—He had a fund of wit, and often rose to eloquence, but his lectures were nevertheless always serious efforts to impart truth. The spontaneity of his wit was wonderful. "Mr. Smith," said he one day in the quiz, "what is the chief proximate principle of the fifth class?" Smith, a bashful youth from the country, blushed and hesitated, and began to scratch his ear. "You have it," shouted the professor in a merry voice, "your finger is on it; it's your ear" (urea).

Essential Paroxysmal Tachycardia Treated with Artificial Serum.—The *Bulletin Médical* of April 22, describes a severe case treated in vain with all the usual remedies, at the fifth day in acute asystole, in imminent danger of death. To retard the cardiac pulsations and increase the arterial tension, Chauffard resorted at last to an intravenous injection of artificial serum. One hour later the patient was breathing freely, with no further distress, and felt "infinitely better." By the next day he was completely restored. Chauffard accepts the results in this one case as offering very favorable indications for the continued use of this "medication with a future," in the severest cases of this disease when the cardiac paralysis and syncope become menacing.

Experiments in the Contagiousness of Pulmonary Phthisis.—It has been asserted that persons sent to resorts for their general health, acquire there the germs of tuberculosis. Some recent experiments described in the *Revue de la Tuberculose*, December, 1895, prove that where the sputa of consumptives, even in advanced stages, is carefully collected and destroyed, there is no contagion. Apartments where deaths from purulent phthisis had occurred were disinfected and animals inoculated with the dust collected from the walls, etc., afterward. Results showed that cleanliness and disinfection are enough to prevent any contagion from inhalation of the dust. Further experiments with animals proved that the most infective forms of phthisis did not communicate contagion where the patients constantly used portable cuspidors in which there was a layer of Van Swieten's solution. There is therefore less danger of contagion at a sanitarium or consumptive resort, where strict measures prevail, than in the every day life of any large town.

The Genuine Prophylaxis of Hydrophobia.—The London papers report that a great activity in enforcing the muzzling ordinance against dogs has taken place. Out of 11,000 dogs lately taken up by the catchers from all parts of London, 9,450 have been destroyed, and the new crematorium at Battersea has been kept in use all day and a great part of every night, in order to deal with the exceptionally large number of bodies that have had to be destroyed. It is estimated that about one hundred and fifty dogs have been suffocated in the lethal chamber every day, and about an equal number have been cremated daily. A total number of 638 animals have been claimed by their owners. Quite two-thirds of the dogs that have been received were fox terriers, and there have only been a very few dogs of really good breed. The daily number of animals that are being taken in is gradually decreasing. This is a sure method of reducing the material susceptible to rabies, and of indirectly stamping out hydrophobia. It may confidently be predicted that the mortality by that disease in 1896 will show a marked reduction.

Abnormal Urethras.—Wölfler treated recently a young girl who had besides the normal micturitions, a continuous slight flow of urine. Examination disclosed a second urethral opening between the first and the vagina. He assumed that there was a double bladder and united the two parts with a com-

pressor similar to Dupuytren's enterotome. He also intended to obliterate the second urethral mouth, but was prevented by a laceration between this canal and the urethra proper, when he performed Gersuny's operation of twisting the urethra, after which there was no further incontinence. Schwarz criticises this treatment in the *Beiträge z. Klin. Chir.*, No. 15, adding the results of observations in about a hundred cases of abnormal urethras, debouching into the urethra proper, the vagina, vulva, or rectum. He asserts that a communication must first be established between the abnormal urethra and the bladder, and then the abnormal outlet obliterated. Such malformations often escape notice in men and do not require surgical intervention, which is necessary in female cases usually. When the abnormal urethra debouches into the cul-de-sac it is a serious matter. Every case of this kind in his experience has proved fatal in time.

Four Years' Course. The Medical Department of the University of Buffalo announces that it has adopted a four years' course, beginning with the session of 1896-97.

Location of Private Asylums in Connecticut.—No asylum, home, or institution for defective, deformed or incurable persons, it was enacted in Connecticut in 1895, shall be established or maintained within the corporate limits of any town without the consent of said town, unless under express legislative authority.

The Intercolonial Medical Congress.—Preparations have been made for the meeting of the Intercolonial Medical Congress at Dunedin, New Zealand, in February next. From Australia, steamers have been arranged to leave all the chief ports in time for the opening of the Congress. The attractive program of the "trips" available for those who attend the Congress has probably influenced a good many of the members of the profession in Australia to make their journey to Dunedin.

Night Medical Service in New York City.—This service, established largely through the efforts of Dr. Henry Nachtel, has been discontinued after having been in operation about fifteen years. Its object has been to afford free medical relief, between 11 p.m. and sunrise, for the needy sick. The physician attending the call is paid \$3 per visit by the city. The discontinuance of this service, done by reason of alleged abuse of the charity, is due to the withholding of an appropriation of \$1,500 per annum by the Board of Estimate, and it is now alleged that a hardship is wrought in the case of many poor persons whose cases are not suitable for hospital treatment. The friends of the service have claimed that it is mandatory upon the financial officers of the city to appropriate the amount named.

Ameba Enteritis. This is Boas' name for a certain form of intestinal catarrh, and he is making a study of it and the microorganisms which produce it. The symptoms are excessive debility, diarrhea and vomiting. The disease lasts about six weeks, when the patient entirely recovers, as the ameba disappears from the stools (Quinke's ameba coli mitis). Animals injected with it did not respond in any way. Boas may have different results from the pure cultures he has succeeded in making now, from the fourth and last case ever observed in Berlin. *Dtsch. Med. Wochsch.*, April 16.

The Enzyme of Schizo-saccharomyces octosporus and Saccharomyces Marxianus. These two yeast plants produce a diametrically opposite effect upon cane sugar and maltose. The first inverts maltose while it leaves cane sugar untouched, from which we can expect that it will not form invertin, but rather glucose. The second on the other hand, inverts cane sugar and not maltose. It was also found that alpha methyl glucosid was induced by the first and not by the second. The experiments were made with a diluted extract of each by Fischer and Lindner, who describe them at length in the *Ber. d. Dtsch. Chem. Ges.*, xxviii, p. 984. *Centralbl. f. Phys.*, April 4.

Qualification for Giving Opinion as to Poisoning.—The question was raised in the Michigan case of People v. Thacker, as to whether a practicing physician, who has read the books and had the benefit of instructors until his mind is so well trained that he is able to take his degree as an M.D., and who is authorized by the law to practice medicine, and to prescribe remedies for persons who have been poisoned, either by accident or design, may express his opinion as to whether a given case is one of poisoning or not, or whether, in addition to the above qualifications, he must have actual experience in poisoning cases before he can testify. The authorities on the subject are conflicting. The supreme court of Michigan holds, March 24, 1896, that such an one is qualified, without the additional experience, to give his opinion as an expert. It thinks that if the witness has given the subject of poisons such careful and discriminating study, by reading the literature of the subject and listening to the lectures of instructors who have made a specialty of the subject, so that his study has resulted in the formation of a definite opinion, that he may express it, and that, when expressed, it may be considered by the jury, which should give the opinion so expressed just such weight as, in view of all the testimony, they think it entitled to. The medical witness whose testimony it specifically holds there was, for the above reasons, no error in admitting, graduated in March, 1894.

Influence of Salt on Chemic Changes.—Bial states that salt, up to a certain amount, has a most stimulating effect upon the growth of the yeast plant; after this point is passed, it ceases to have any effect, while if still more salt is added, it checks and destroys the plant. In administering salt, therefore, to check the gastric fermentation, it is very important to experiment carefully until the exact amount of salt required is determined, as different quantities produce opposite results. Ewald has secured excellent results with salt direct in such cases. Scheurlen has arrived at a similar conclusion by a different path, showing that the disinfecting power of carbolic acid can be very much increased by adding salt; even the most rebellious anthrax spores are destroyed by the combination. Gans also announces that carbonate and bicarbonate of soda retard notably the transformation of glycogen, in his experiments with a mixture of glycogen and diastase, while chlorid of sodium and Glauber's salt have no effect either way. This result confirms our ideas in regard to the action of alkalines in diabetes. *Dtsch. Med. Wochsch.*, April 16, and *Sem. Méd.*, April 22.

Free Bacteriologic Diagnosis of Diphtheria in London.—If we mistake not, the first civic division of London to adopt an independent laboratory for the modern diagnosis of diphtheria is that of St. Marylebone, under the direction of Dr. Wynter Blyth. The *Medical Press* says: "The experiment now being carried out in Marylebone of furnishing apparatus and opportunity for free bacteriologic examination in doubtful diphtheria will be watched with much interest by all who are interested in public health progress. Its results during the quarter have been as follows: Twenty-one cases of presumed diphtheria have been examined, and of these eleven, or rather more than half, showed the typical microphyte. The actual number of cases of diphtheria notified during the period in question was seventy-five, of which number forty-one were removed to a hospital. These figures show a marked increase over the corresponding period of 1894, when sixty-seven cases were officially reported. In view of the alarming spread of this fatal but quite preventable disease, Dr. Wynter Blyth is to be congratulated on his action in affording medical men in his district an opportunity at arriving at an absolute and early diagnosis in doubtful cases of sore throat."

Doctors' Right of Way. Over eight hundred physicians of Chicago have already taken advantage of an ordinance passed by the Council, giving them the right of way on the streets and over bridges ahead of processions, parades, fire lines and

other obstructions that usually stop their ordinary traffic. Each of the physicians applying has been furnished with a badge and a special permit, which entitle him to the privileges of the ordinance and demonstrate his authority. The badge is a very pretty affair, about the size of a quarter, made of German silver in the form of a circle 3-16 of an inch wide, around a red cross in the center. The cross is of red enamel and the circle white. The ordinance also applies to ambulances, and is made to include all physicians driving in answer to professional calls, to fires or accidents. It is designed to afford relief as quickly as possible to people who require the services of a physician. The permits are signed by the Mayor and City Clerk, and the badges are issued from the City Clerk's office on the payment of a 50-cent fee.

Hippocrates on Waters.—Whoever wishes to investigate medicine properly should proceed thus: . . . We must also consider the qualities of the waters, for as they differ from one another in taste and weight, so also do they differ much in their qualities. Concerning the waters which the inhabitants use, whether they be marshy and soft, or hard and running from elevated and rocky situations, and then if salty and unfit for cooking; and the ground whether it be naked and deficient in water, or wooded and well watered, and whether it lies in a hollow confined situation, or is elevated and cold; and the mode in which the inhabitants live and what are their pursuits; whether they are fond of drinking and eating to excess and given to indolence, or are fond of exercise and labor and are not given to excess in eating and drinking. From these things he must proceed to investigate everything else. For if one knows all these things well, or at least the greater part of them, he can not miss knowing when he comes to a strange city, either the diseases peculiar to the place, or the particular nature of common diseases, so that he will not be in doubt as to the treatment of the diseases or commit mistakes.—HIPPOCRATES ON "Airs, Waters and Places."

A Clergyman's Good Word for the Medical Profession.—The Rev. Dr. Talmage says, "Bless the doctors," and contends that there is too much fault-finding among the general public with physicians, especially when the patient fails to recover.

So far as I know them, physicians profess to be neither omnipotent nor all-wise. Like those of us in other professions and occupations, I suppose they sometimes make mistakes; but the time we spend in sarcastic flings at their Christ-like and magnificent calling we had better spend in thanksgiving to God for what they accomplish. Better not be too hard on the doctors. Sooner than you expect you will be sending for them, and between you and the King of Terrors there will be nothing out one of their prescriptions. They stand to-day, as a profession, fighting back whole armies of cancers, pneumonias, phthisias, and congestions of brain and liver and lung. They do more missionary work than any class of men in the country, and upon them will come the blessing of the Great Physician, as he says, "I was sick, and ye visited me." When the last illness of body is cured, and the last attack on the children's cradle has been discomfited, and the last broken bone of workman fallen from the house scaffolding shall be set, and the last wollen gum of teething child shall have been lanced, and the last pale patient with tumor successfully removed shall, with a grateful "Thank you, doctor," be released from the operating table in the clinical department of the city hospital, then it will be time enough to deride the medical profession. Christ go along with him in his journeying a physician, one Doctor Luke, and while some in that calling are sceptical and atheistic, many of them know how at the same time to medicate body and soul.

An American Citizen and Physician Wounded in Cuba.—Dr. Jose Manuel Delgado, who has been a storm center of considerable international correspondence, is a graduate of Bellevue Hospital Medical College of the class of 1872. A dispatch from Washington gives the following recent information regarding the progress of the case. In addition to the removal of the commanding officer who led in the outrage and wounding of the American citizen, Dr. Delgado, steps will be taken to

press a claim for money damages. Consul General Williams has submitted a great deal of information to the State Department, including sworn statements from both Dr. Delgado and his father, Joaquin Delgado, as to their citizenship, with descriptions as to the occurrences of March 4. Perhaps the most important evidence is that which shows that Captain General Weyler, when he received a protest from Consul General Williams, promptly stopped the proceedings which were in progress on the Dolores plantation, and had Dr. Delgado, who had been cut and shot, removed to a safe place, where he was given the best medical attention. Dr. Delgado fortunately recovered from his wounds, but is still in Cuba looking out for his plantation. No suggestion has reached the department as to the amount Dr. Delgado will claim for the injuries sustained by himself and men, as well as for the damage done his estates. Mrs. Mussey has not yet heard from Delgado on this point, and until she does she will take no action looking to the filing of his claim. When Dr. Delgado's claim is submitted the department will have two claims to press from this family. Mr. Delgado, the father, had his estates embargoed by the Spanish in 1869, and the Claims Commission which assembled a few years later awarded him damages to the extent of \$117,000. The matter has been close to settlement several times, but payment has never been made.

The Trendelenburg Position in Prolapse of the Funis.—The London *Lancet* has the following comment and commendation regarding that recent contribution of Dr. R. Abrahams to the *American Journal of Obstetrics* on this subject. "He relates a case in which his attention was accidentally called to the value of this position in the treatment of prolapse of the cord. It was a case in which the vertex presented. On rupturing the membranes a very large quantity of liquor amnii escaped, and a portion of the umbilical cord, estimated to be ten inches in length, was carried down by the gush of the waters into the vagina. The os was fully dilated, and the best plan seemed to him to be to deliver the woman either by forceps or version as quickly as possible. The patient's surroundings were of the poorest possible description, and the bed on which she was lying was 'a wide long board with four poles as feet to rest on.' While he was trying to get the patient in position for operating the foot of the bed gave way. This necessitated the raising and holding up of the foot of the bed some six feet from the ground while the supports of the bed were being repaired. On lowering the bed after this had been at last accomplished he examined the patient, and was surprised to find that no part of the cord was to be felt in the vagina and that the head was fully engaged. Delivery was effected quite naturally without any assistance. Dr. Abrahams ascribed the change in the condition of things to the extreme Trendelenburg position caused by raising the foot of the bed to the height above mentioned; and this appears most probably to be the true explanation of the sudden recession of the cord. He considered the Trendelenburg position much superior to the genupectoral position formerly recommended for these cases, as being more comfortable for the patient, but, on the other hand it has the disadvantage of causing difficulty in breathing. Still, as the position may only have to be maintained for a short time, as in Dr. Abraham's case, treatment of prolapse of the funis by the Trendelenburg position seems to deserve a trial."

The Lebel Sword Bayonet of the French Army.—The *Courier des Etats Unis*, in a communication dated April 22, 1896, has the following concerning wounds by the Lebel bayonet. Since the adoption of small caliber firearms there has been little opportunity in Europe at least, of observing wounds caused by the sword bayonets or poniards associated with the rifles. For a long time it was considered that these wounds ought to be more deadly than those occasioned by the old style saber bayonets;

but recent observations have modified completely this opinion and proved that the lesions produced by narrow bladed weapons heal readily notwithstanding probable intestinal perforations, and without the necessity of resorting to laparotomy. It is admitted now that the thrust of sword bayonets or poniards being at the moment of penetration much more feeble than that of a rifle bullet the triangular or quadrangular blades may push aside the intestine or even push it before them without perforating it: and even should they perforate, that the wound would close spontaneously and quickly. Several observations on accidental injuries give every reason to believe this: the last made by Surgeon-major Guichmerre on a soldier of the reserves, who on Oct. 17, 1895, was pierced by a sword bayonet, model 1886, in an assault during a sham fight and grievously wounded in the abdomen. No surgical interference was undertaken in this case and on October 20 the patient was much improved: on the 21st he was able to eat an egg and on the 30th he was discharged from hospital cured. It is to be noted in this connection that foreign powers have generally adopted poniards with a blade 25 to 30 centimeters long, while that of the Lebel sword bayonet is 518 millimeters.

Presumption as to Continuation of Sanity.—Every man is presumed to be sane. This presumption of sanity, the supreme court of Mississippi holds, in the case of *Ford v. State*, decided March 30, 1896, will be sufficient to sustain the burden resting on the State of proof of sanity on the part of the defendant at the time of the commission of the act charged if the defendant offers no testimony sufficient to raise, out of the evidence in the case, a reasonable doubt of the defendant's sanity at the time he committed the act. Where general, habitual insanity is shown to exist, it is presumed to continue, and the burden of showing that the act was committed in a lucid interval is upon the State, and in the sense that that burden is not satisfied by any presumption of sanity, but must be satisfied by proof on the part of the State of the lucid interval at the time of the doing of the act. But if only temporary or recurrent insanity, as from paralysis or epilepsy, be shown, there is no presumption therefrom of continued, general, habitual insanity. And when all that the evidence in the case shows is this latter form, temporary insanity, without raising a reasonable doubt as to whether it existed at the time of the act in question, the State may rely on the presumption of general sanity with which it started out, without offering proof as to the lucid interval; for the presumption of sanity with which the defendant is invested at the outset is a general and universal one, embracing, as a whole all its parts, the included presumption of sanity at all times, including the particular time when the act in question was committed, unless the evidence raises a reasonable doubt, not of temporary, but of general insanity, and hence of insanity at the particular time.

A Physician Exercises the Priestly Office. A poor New York lad, named Kyle, started away from home to seek his fortune, with some of his comrades, and began by trying to steal a ride on a freight train. The engine had hardly gained good speed before Kyle was jolted from the trucks to the rails. The wheels of the caboose passed over his legs and cut both off below the knee. His companions saw his plight and jumped off to go to his assistance. They managed to bind up the wounds with their handkerchiefs and the lining of one of their coats. Then they carried Kyle to the banks of the Hudson, near by, and made a bed for him on the grass. The station agent at Spuyten Duyvil had seen the accident and ran to the spot. When they saw him coming Kyle's companions ran away. The station agent summoned Policeman Shea, who called an ambulance from Fordham Hospital. As soon as the policeman had left, Kyle took a string of beads and the prayer book from his pocket. He went over the beads carefully and placed the cross upon his breast. Then he opened the prayer book and in a

faint voice began to read. A crowd gathered about the boy, anxious to relieve his sufferings. He thanked them and said he knew he was going to die. "But God bless you all," he continued, "I'll read a prayer for your salvation." Every head was bowed as the Latin words came in faint tones from the dying lad. Then the ambulance came and Kyle was placed inside by Dr. Riley. The boy became faint, his eyesight began to fail him. "I can't see to read," said he to Dr. Riley. "Won't you read me some prayers?" The Doctor took the book from the boy's hand and read to him till the hospital was reached. Then he was placed in bed, but he would relinquish neither the prayer book nor the beads. The poor lad shortly afterward became unconscious and death took place about midnight.

The Duty of the General Practitioner Toward the Feeble-Minded.—The editor of *Archives of Pediatrics* calls attention to the question of the responsibility of the family physician when he finds feeble-minded children in the families he attends. The relation is one that deserves his thoughtful attention, for he can assist these little unfortunates, not only as an adviser regarding their mental and moral training, but also in his capacity of physician. Feebleness of body frequently attends and increases feebleness of mind. There is a general sluggishness of the whole physical being, involving especially the organs of sense. This is not so much due to lack of mechanical perfection as to non-perception at the brain centers. The mind, therefore, lacks the constant spur to activity which that of the normal child receives. The child is to a great degree deprived of the knowledge commonly gained through the medium of the five senses. "The circulation of these children is slow and imperfect. They are therefore especially sensitive to cold and should be clothed more warmly than ordinary children. They eat slowly and generally digest the food well, but are subject to constipation. The diseases to which feeble-minded children are liable are asthenic in character. Phthisis, catarrhal pneumonia, bronchitis, ulcers and all forms of disease engendered by weak circulation and low vitality are common among them. If attention to hygiene is essential in normal children, it is doubly important in the case of the mentally feeble, in order that no unnecessary burden may be imposed upon those who are already so heavily handicapped. There is no special or specific treatment for most cases. Massage, by stimulating the circulation, sometimes proves of considerable assistance. Craniectomy will perhaps benefit a few cases of microcephaly, but their number is extremely small; its most successful application in the vast majority of cases is in its non-performance." Thyroid treatment of the cretinoid type has proved successful in many well-authenticated cases, and is established as a safe and legitimate method of treatment. It should be a recognized fact that the treatment must be continued as long as the child lives, if he is to remain healthy. In other types the medical treatment should consist in maintaining the nutrition at as perfect a point as possible and in diminishing as far as may be all inherited and acquired tendencies to disease.

Medicine Among the Arabs. A German scientist and physician spent six months lately in the Sinai Desert to collect certain data, and incidentally noted some interesting facts in regard to the diseases prevalent among the Bedouins and their treatment of them. He never found the slightest trace of tuberculosis, and therefore announces that the ideal sanitarium for consumptives might be erected there, if the desert were not so absolutely inaccessible, as it is the only place yet discovered where this disease is unknown to the native population. But it requires a train of camels and attendants to penetrate into the country. He found no trace of venereal disease, except among those Bedouins who had lived in Egypt. There are no doctors nor surgeons, and child-birth is accomplished in a standing posture. If the presentation is wrong, the woman is

placed in a strong cloth and shaken or bounced until the position of the fetus is changed if possible. Puerperal fever is frequent, as might be expected from the lack of cleanliness, and the old women proceed to drive out the fever devil by sticking red hot needles in the woman, beginning at the head and ending by driving him out at the feet, while all howl in chorus. Malaria prevails in Tor and other low places, but the mountains are always a sure retreat in the malarial season, where escape is also found from the cholera trailing after the pilgrims returning from Mecca.—*Dtsch. Med. Wochsch.*, April 9-16.

Primary and Secondary Lesions of the Nerve Cells.—Marinesco has been continuing Nissl's histologic studies of the nerve cells, and reported as follows to the Société de Biologie, January 25: It is known that the nerve cell is composed of a homogeneous, fundamental part (trophoplasm), which contains within it elements colored strongly by the basic anilin colors—chromophilic elements, or kinetoplasm, surrounding the nucleus and radiating into the protoplasmic elongations. The axis cylinder, of a fibrillary structure, belongs with the fundamental part of the cell, to the trophoplasm. The trophoplasm presides over the nutrition of the nerve and muscle fiber. The kinetoplasm is an apparatus destined to transform sensory or motor impressions. After section of a motor nerve, the kinetoplasm disappears progressively, from the periphery to the perinuclear layer. The axis cylinder and the myelin remain intact. The absent kinetoplasm may reappear if the trophoplasm is not altered. If the trophoplasm is affected, the axis cylinder becomes atrophied and degenerates. From these studies, Marinesco announces the pathogenesis of peripheral neuritis: The lesions of the central end, incorrectly called ascending neuritis, are due to the alteration of the trophoplasm of the nerve cell. Primary affections of the spinal cord induce at the same time, a lesion of the kinetoplasm and of the trophoplasm.—*Revue Int. de Méd. et de Chir.*, April 10.

The Surgical Staff of the Cuban Force.—The *New York Herald* correspondent in Cuba writes that the surgical corps in the Cuban army consists of eighty physicians, distributed among its six different corps. The head of the service is Dr. Joaquin Castillo Duany, surgeon general, a graduate of an American university, and formerly attached to the United States Navy, in which capacity he formed part of the crew that started in the *Rodgers* as a relief expedition to the *Jeannette*. When the present revolution broke out he was medical inspector at the Juraque iron mines. He joined the ranks of the Cubans, together with Mr. Kilpatrick, one of the managers, and several other employes, all Americans. Surgeons in the Cuban army have no limited time of service, receive no pay, acquire no fame or rank. These men, brought up under the refining influences of civilization, abandon their practices, their homes, their families, and start on a gloomy career of hardship and danger, with the possibility of being caught by the Spaniards and shot by the roadside. The surgeons are all provided with first-class French instruments, and in their operations they always make a lavish and intelligent use of antiseptics, for in Cuba's burning climate tetanus and secondary suppurations set in with astonishing rapidity. Drugs are often hard to obtain, there being no regular base of supplies. In many cases where mercury, bichlorid, iodoform and carbolic acid are unattainable, wounds are sprinkled over with finely powdered burnt coffee, which proves a powerful antiseptic. Fevers are often and successfully treated, in default of quinin, with a decoction of the "cundeamor," leaves from creeping plants of valuable febrifuge properties. As alcohol can be had plentifully at any sugar plantation in a reasonably pure state, tinctures of many native plants are constantly prepared which are found effective by previous trials. Chloroform and ether are things unheard of in those wildernesses, and nothing illustrates more graphically the Spartan heroism latent in the

Cuban nature than the unflinching way with which they submit in full consciousness to the ominous knife. It is not strange to see a man there light his cigar and look on coolly while his arm or leg is being amputated, just as if it were a matter of no concern to him.

Indorsement as a Legally Chartered Medical School.—A graduate of the medical department of the Laval University, a legally chartered medical college in Montreal, Canada, applied for a certificate to practice medicine in Rhode Island, but was refused one by the State board of health, on the ground that Laval University had not been indorsed by them as a reputable and legally chartered medical college. It appeared, however, that if he had presented with his diploma a license to practice medicine in Canada from the College of Physicians and Surgeons, a board similar to the State board of health of Rhode Island, the latter would have granted him a certificate to practice. And the evidence showed that the license of the college of physicians and surgeons was granted as a matter of course to those holding diplomas from the Laval University, who, like this party, had been found by the governors of the college of physicians and surgeons qualified to pursue the study of medicine, and had been registered in the books of the college as having commenced the study, on the payment of the prescribed fee. Moreover, the evidence showed that in several instances the State board of health of Rhode Island had granted certificates to practice to graduates of Laval University, who, having practiced medicine in Canada prior to coming there, had the license of the college of physicians and surgeons. If this was so, inasmuch as the license of the college of physicians and surgeons was granted to holders of diplomas of Laval University, of the class mentioned, without examination, merely on the payment of a prescribed fee, the supreme court of Rhode Island holds, *Boucher v. State Board of Health*, Feb. 11, 1896, that the granting of certificates by the State board of health to other graduates of Laval University, qualified as above stated, was, in effect, an indorsement of that university by them as a legally chartered medical college, to the extent mentioned, and that they therefore erred in refusing a certificate to this applicant merely because, not wishing to practice in Canada, he did not pay the fee and obtain the license from the college of physicians and surgeons.

Arkansas Prefers County Medical Examiners.—A law was passed in Arkansas in 1895 providing that the county courts of the several counties of the State shall appoint a County Board of Medical Examiners in and for their respective counties: such board to consist of three members, learned in the sciences of medicine and surgery, of good moral character, and duly registered, while two members of the board shall be graduates of some reputable medical college. The term of office is four years. But the county judge may at any time remove any county examiner for drunkenness or other immoral conduct. Each board is to hold at least two meetings a year at the county seat. In counties having two judicial districts there may be appointed two separate boards, one for each district, in the same manner and with like effect as provided for separate counties. The County Board of Medical Examiners is authorized to examine all persons who may desire to practice medicine who are residents of the county with the board, that may apply, and if found qualified to practice medicine and surgery, issue a certificate which shall entitle the holder to practice in the county in which it is issued or in any county into which his practice may extend, so long as his residence remains in the county wherein the certificate is issued. Such applicant shall pay the county board a fee of \$6 for the examination. Sections 4968, 4969 and 4970 of Sandels and Hill's digest, providing a State Board of Medical Examiners and the issuance of licenses by it, and all other laws in conflict with this 1895 enactment, are repealed. This bill, it is stated in a footnote

signed by the Speaker of the House and President of the State Senate, having been returned by the Governor with his objections thereto, and after reconsideration, having passed both houses by the constitutional majority, it has become a law.

Resection of the Wrist by a Dorso-palmar Incision.—At a recent meeting of the French Association for the Advancement of Sciences, M. Francis Villar, of Bordeaux, read a paper on resection of the wrist by the double longitudinal incision. Resection of the wrist, he says, is not much in vogue among surgeons. This is probably because the results for a very long time were not extraordinary, but since the antiseptic method and the researches of Professor Ollier, we are better able to judge of its value. The mortality is practically *nil*, and the functional results are often perfect. The methods of operating at our command are few in number, and attention is directed to the method under consideration which is but little known, but which will render valuable service at least in certain cases. Introduced by Studsgaard in Copenhagen, and practiced by Novaro, Bassini and Odisio in Italy, it does not seem to have attracted French surgeons, for Villar has been unable to discover any other case than his own operated on in 1893. The method is as follows: The incision is commenced on the back of the hand a little above the line of the radio-carpal joint and is prolonged to the end of the web between the third and fourth fingers. The extensor tendons are held aside and the interosseous muscles divided. The first incision is now continued from the web on to the palmar surface and up to the line of the joint or a little higher. This done the soft parts of the palm are divided, taking care to avoid the tendons and the median nerve. The superficial palmar arch is tied. If the two parts of the hand are widely separated (one of these consisting of the first three fingers, the other of the remaining two) the carpus is reached and nothing is left save to extirpate the different bones. While at first sight it would seem that this method causes considerable mutilation, repair takes place rapidly, as the cases published show. There are two striking advantages connected with this method. 1. It is much easier than the classic methods. It is no small task to separate the carpal bones connected by strong and resisting ligaments through the ordinary incisions. 2. It gives considerable room and allows osteo-articular or tendinous lesions to be followed throughout their whole extent. The therapeutic and functional results are excellent, and the method is especially indicated in cases of extensive lesions. (*Le Bulletin Médical*, 1895, No. 67.)

Operation for Epithelioma Incidentally Cures Prostatic Hypertrophy.

—Mr. Southam, of Manchester, England, is reported in the *British Medical Journal*, as reporting upon the favorable effects of castration for prostatic hypertrophy. In one case the patient for more than two years previously had passed no urine except by catheter. On the fifth day after the operation, which was performed as self catheterization had become very painful, difficult, and attended with hemorrhage, he began to regain the power of voluntary micturition and he could now dispense with the catheter, the urine being passed in a feeble stream with slight straining. To illustrate the effects of double castration upon the prostate, Mr. Southam also showed a patient, aged 71, on whom he had operated fifteen years previously for epithelioma recurring in the stump of the penis after amputation, both testes together with the remains of the penis and the entire scrotum being removed. There had been no further recurrence, and on examination by the rectum at the present time no indication of the presence of the prostate could be detected, its position at the neck of the bladder being represented by a depression or sinking in of the anterior wall of the rectum at this spot. The same journal quotes Albarran in *Presse Médicale*, as drawing a discrimination between the effects of castration upon the contractility of the bladder, and

upon the prostate, and between the effects upon the latter organ when hypertrophied and when normal. The writer has observed that in many cases after operation a rapid shrinking of the prostate is observed to follow in from one and one-half to two months. The glandular culs-de-sac, instead of being pressed together, are found separated by large spaces into a series of independent glands. There is a degenerative disintegration of epithelium which before disappearing takes on an embryonic type, but there is no proliferation of muscular or connective tissue: these appear abundant owing to the shrinking of the glandular tissue. Double castration causes atrophy of the normal, but not necessarily of the hypertrophied prostate, and evidence on this latter point is wanting. Clinically speaking, an atrophied prostate is one which has ceased to be felt by the rectum. But congestion accounts for at least one-third of the enlargement, and relief of retention where it exists is usually due to the diminution of this. Diminution of the volume of gland admits of increased vesical contractility, and thus aids in relieving or curing the retention. The value of operation lies in securing these results. In dysuria without retention, where the vesical and prostatic congestion causes frequent micturition, though castration gives relief, any measures for the diminution of the cystitis also relieve, and operation is unnecessary. In acute retention the operation is not called for. In incomplete retention, benefit is obtained for the reason that as the prostate becomes atrophied, the bladder acts with greater freedom. In chronic complete retention, complete cure often results, if there is no marked thickening of the walls of the bladder.

Centenarians of Chili and California.—In a recent issue of *Leslie's Weekly* is an illustrated article giving information regarding and photographs of some of the very old men and women of the American continent. The writer says:

The last census of Chili shows an unusual proportion of extremely old people among the population, there being 211 men and 223 women in that country who have passed the century mark. The age of the oldest, Rafael Munoz, of Colchaqua, was returned to the enumerators as 150. Three others were more than 130, and thirteen had passed 120, while fifty-three women and thirty-eight men gave in their ages as 110. A full report of the centenarians in the United States would surprise many of its readers, for the number of men and women who have attained great age is much larger than is generally supposed: and if the old could defy such accidental diseases as *grippe* and pneumonia their limit of life would be considerably extended. If in Chili the conditions are such as to prolong life, it would seem that California, particularly its southern portion, must be an equally favorable place for longevity. The climate is similar to that of Chili, and the mode of living among the natives does not differ greatly. There are some very old people in this State. As an out-door life tends more than anything else to longevity, it is not surprising to learn that the oldest man of whom we have any record in the United States was an Indian. His name was Gabriel, and he was a well-known character of Castroville, Cal. until he died in 1890, at the age of 147. There is now living in Southern California an Indian chief, the head of the Sobobo tribe, who is 136 years old and has a wife considerably past 100. There is an Indian dame at San Gabriel whose age is vouched for at 118. Close by the walls of the best preserved mission on the coast live three venerable women who are widely known as "The Belles of San Luis Rey." One of them claims to be 128, and the others are more than 120. They saw the first mass that was celebrated in the mission walls. Relics of bygone era, they appear to enjoy the attention which every visitor bestows upon them, but they are decidedly averse to the camera, and were with difficulty persuaded to sit for the photograph. In the Mexican division of the grand *fiesta* procession at Los Angeles, in the spring of 1894, rode Don Ygnacio Francisco de la Cruz Garcia, upright, apparently vigorous, managing his horse with the skill of a *caballero*. No person unacquainted with his history would have surmised that he had long passed the century mark, yet his age was 113. He is now often seen walking near his home in the city, and is in possession of all his faculties, even that of sight, although at one time he was totally blind. There can be no doubt about his age, for he holds a certificate for his baptism on May 4, 1781, in a Catholic church at San Jose de Gracia, in Mexico. He has a son 86 years old and his youngest child is 60.

A Mild Protest Against Bacterial Diagnosis at the London Pathological Society.—An editorial comment in the *Medical Press and Circular*, on the recent discussion before the Pathological Society of London, shows that some slight "conservative" opinion still exists in high circles regarding the bacterial diagnosis of diphtheria. The following is a portion of the editor's cautious, almost gingerly, handling of his subject. The editor's heart is in the right place, however, and this is a part of what he has to say: "It seems that virulent diphtheria bacilli may linger for an indefinite period in the mouth secretions of persons who have recovered from an attack: indeed, in a case mentioned by Dr. Hewlett at the Pathological Society, they were detected twenty-three weeks after the onset of the malady. This observation possesses a special significance, in view of the fact that the later investigations were undertaken at the behest of a schoolmaster who feared that the lad might, on his return to school, be the means of disseminating the disease; a well-founded suspicion, as events proved it to be. Mr. Butlin, the president, took advantage of the opportunity to review the situation in respect of the bacteriologic diagnosis of diphtheria. It seems that medical practitioners in the district where he resides are now provided by the authorities with the necessary facilities for obtaining expert opinion in respect of the secretions in suspected cases, an excellent innovation one would think, but one which he nevertheless seems to think somewhat vexatious. He also referred to the practice in the larger cities of the United States, where he assured them it had become the custom for the medical officer of health to at once visit and inspect all reported cases of diphtheria without going through the usual formality of asking the practitioner in charge to meet him in consultation. Mr. Butlin appears to dissent from the idea that the diagnosis shall be determined solely on bacteriologic data, and he suggested that the society might 'do something' to clear up a situation which, in his opinion, was full of danger to the public as well as to the profession. Before anything can be done, however, it will be necessary for us to know exactly what the danger is and how it is brought about, points as to which Mr. Butlin was silent. He questioned the importance attached by the speaker to the presence of these virulent bacilli after so long a period, and suggested that there were probably hundreds or even thousands of persons similarly inhabited by virulent bacilli wandering up and down the country apparently without detriment to the public welfare. How he arrived at the 'without detriment' conclusion he did not say. It occurs to us that possibly the existence of these ambulatory foci of infection may explain the ever increasing spread of the disease in spite of all the precautions that have been taken to check its ravages. We must confess that we do not clearly see what the society can do to clear up the situation. The Pathological Society, of all others, could hardly venture to throw cold water on the value and importance of bacteriologic investigation, but unless they declare bacteriology to be a scientific fad and a delusion, it is difficult to see how they can enter [a protest against its practical application to diagnosis. If the culture from the saliva of a given person is capable, as in Dr. Hewlett's case, of determining the death of guinea pigs in a few hours, even Mr. Butlin would hardly wish to introduce him to his family circle, his skepticism to the contrary notwithstanding. This being so, his protest would appear to be singularly inopportune, and, as coming from the President of the Pathological Society, somewhat regrettable." This may, we think, be taken for the last expiring protest by the "conservative element" against the full and free adoption of modern laboratory diagnostic work.

A Proposed Diploma Mill Under British Flag.—The *British Medical Journal* pours hot shot into "The College of Physicians and Surgeons of Bengal," which a few medical practitioners of Calcutta have formed into a voluntary association for the dou-

ble purpose of corporate combination and medical education without state aid or interference. Practitioners throughout India have been invited to become members of this "College" without ceremony or test, and fellowships on similar terms will no doubt be instituted ere long. A medical school has been started, and was declared open on January 13, by Dr. Juggobundo Bose, who delivered an inaugural address on the occasion. A prospectus of this school has been published. The curriculum is to extend over four years. Students are to pay the modest sum of 3 shillings and 6 pence for matriculation, and a fee of like amount monthly in advance for instruction. Courses of dissections, of practical chemistry, and of practical physiology are to cost severally three rupees extra. The diplomas L.C.P. and L.C.S. are to be conferred at the end of the curriculum after examination, for which a moderate additional fee of 25 rupees is claimed. The subjects of examination are stated. A president, four vice-presidents, and lecturers have been appointed, and the whole scheme looks very regular and complete on paper. No state sanction or charter has apparently been obtained for this enterprise, no capital provided, no arrangements made for dissections or hospital instruction, no library, museums, or laboratories established; no provision made for practical teaching of any sort. The instruction imparted would seem to be exclusively oral, and the character of the final examination may be judged of by the fact that "operations on the mannequin" is one of the tests. With every sympathy for any movement which has for its object the consolidation and coöperation of the medical profession in India, and the exercise of self-help in medical education, we can not help entertaining a strong doubt whether this scheme, as at present constituted, is likely to be a sound and safe one, or to accomplish the end which all wishers of India desire, namely the elevation of the medical profession and the larger participation of locally educated men in the medical and sanitary work of the empire. The requirements of a complete and practical education in medicine are so many and so costly in these days that it is a matter of amazement how any combination of medical men in India can have the hardihood to propose a scheme of training and licensing medical practitioners without having in the first instance and as a necessary preliminary obtained the funds and appliances and organized the arrangements requisite for scientific instruction. It is equally a subject of wonder how the government of the country can tolerate a dangerous and retrograde enterprise of this character. The graduates and licentiates of Indian universities and schools obtain their qualifications to practice under sanctions and conditions which ensure a thorough training according to modern principles and methods, and stamp their status in the community with authority. The so-called "College of Physicians and Surgeons of Bengal," as at present devised, is a sham, and its licentiates will, if no change takes place, constitute a very inferior class of medical diplomates. There is unfortunately no council of medical registration and education in India to safeguard the public against pretence and incompetence. But the government is able, through the universities, to control educational matters and insist that educational institutions shall be properly equipped and officered, and competent to impart sound instruction.

Practical Notes.

The Thyroid Preparations at the Medical Congresses in April.—Ewald's masterly critique of this subject was the feature of the XIV Congress für innere Medizin, held at Wiesbaden. It was in favor of the new medication, which he considers a very valuable contribution to therapeutics, especially Baumann's Thyro-iodin, to use in fighting myxedema and goitre. Thyroid medication for fibroma of the uterus was also the leading article presented at the Congress at Carthage, by Jouin, of Paris, who has obtained marked improvement with it in fibrous uter-

ine tumors and obstinate metrorrhagia, and suggests that it may yet be found invaluable in the early stages of tumors, sarcoma, etc.

A New Antiseptic Tablet for Nasal Solutions. The *American Therapist* states that Dr. Murray McFarlane, of Toronto, having become dissatisfied with Seiler's and Dobell's solutions as being too irritating in the majority of cases, has used with success a tablet containing the soluble salts of the blood plasma, which when added to two ounces of lukewarm water, forms a solution like blood plasma. Each tablet contains one-sixteenth of a grain of menthol.

Theobromin as a Diuretic. Huchard announces that he has found theobromin a very valuable diuretic in cardiac and renal troubles, and has studied it carefully in more than two hundred cases. Its action is prompt, reliable, and often succeeds where digitalis and caffeine have failed. A medium dose is two or three grams a day in half centigram powders, although as much as four or five grams can be given with impunity. Combined with a milk diet the therapeutic results are exceedingly satisfactory in infective diseases. *Union Médicale*, March 7.

Boas' Powders. These powders are valuable in relieving the attacks of pain in gastric ulcers:

R. Exalgin	3.00
Extract of belladonna	0.30
Phosphate of codein	0.30
Sugar of milk	5.00

Misce. Sig. Make ten powders. Take one as the attack comes on. Pure codein or the hydrochlorate can be substituted for the phosphate. *Semaine médicale*, April 8.

Insufflation of Air in Tuberculous Peritonitis. When the patient is so invaded by tubercular lesions in the pleura and lungs, fevers, etc., that he is unable to stand the shock of a laparotomy, simply puncture and the introduction of air into the peritoneum, will often bring relief, and the physician should always resort to this supreme means, instead of passively allowing the case to proceed to a fatal termination without it. This method may even prove more beneficial than laparotomy, and Mosetig Moorhof considers the introduction of air under pressure more liable to be followed by success than a laparotomy. Lenoir in the *Revue Int. de Méd. et de Chir.*, April 10.

Carbonic Acid in Sterility. By its stimulating effect in the peripheral nerves, and especially on the sexual system, carbonic acid in the form of water or gas baths, has a direct beneficial action in cases of masculine impotency, particularly in premature senile impotency, and in female dyspareunia and anaphrodisia (absence of sexual excitation), to which sterility is often traceable. It is also recommended in neuralgia of the uterus and ovaries and in dysmenorrhea. It is especially valuable in amenorrhea, administered in gas baths, gas douches and carbonic acid salt baths. Conditions of excessive sexual excitability strictly contraindicate its use. Schuster, of Nauheim, in the *Therapeutische Wochenschrift*, March 15.

Formol, Formalin, Formaldehyde. The use of this substance is increasing and growing more important every day in therapeutics, industry and for many other purposes. This *Journ. Nat.*, pages 543, 588, 645, 695, has described its application to ophthalmology, dentistry, the disinfecting of catgut and the preservation of specimens. The *Therapeutische Wochenschrift* of March 15, reports some later therapeutic successes with it. Gaylord and Frank have found it extremely beneficial in ulcus molle, in a 10 per cent. solution with which they painted the surface of the ulcer, which heals and sheds the cauterized surface in less than a week. The pain is severe but soon passes away. Also condylomata acuminata yields to this treatment. Lamarque uses a 1 per cent. solution of formaldehyde in cystitis tuberculosa, or instills it once a

day in a 5 per cent. solution. Barabaschew recommends it in a 1 to 2000 or 1 to 4000 solution in chronic inflammatory conditions of the connective tissue membrane.

Myoclonia. The meeting of the Association for Psychiatry and Neurology in Vienna, February 11, was mainly devoted to a discussion of this subject, as a patient was presented, suffering from a typical case that had commenced a year and a half previously. The paroxysms were violent, lightning-like contractions of the whole muscular system, from which only the muscles of the eyes, tongue and the peripheral muscles were exempt. One member was impressed with the resemblance between these spasms and those produced in animals by the removal of the thyroid glands. He had already treated cases that showed somewhat similar symptoms, combined with struma, with thyroid extract, and the cramps had disappeared. This treatment was recommended for this disease generally, and especially this case. *Wiener klin. Rundschau*, March 15.

Hydrotherapeutic Treatment of Multiple Neuritis.—Suggested by Pospischil of Krems, this treatment has the advantage that it can be employed from the very first moment of the acute attack instead of waiting, as usual, for further developments. The painful members are wrapped in a bandage dipped in ice water, outside of this there is a layer of cotton, all held in place by another bandage. The bandages are removed and replaced with fresh two or three times a day. A small quantity of sublimate added to the water, is a wise precaution to render the bandages aseptic. The pains subside rapidly with this treatment and the members cease to be contracted; when this arrives, in the course of two to three weeks, while the attack is still acute, the whole body is wrapped in a wet cloth, and then rolled in a blanket and an eider down placed over the patient. The intense perspiration thus induced hastens the elimination of toxins causing the disease, and exerts a most favorable effect upon the whole system. *Semaine Médicale*, April 29.

Antidiphtheritic Serum Administered by Rectal Injection.—Dr. Chantemesse, of the Pasteur Institute of Paris, has advised the exhibition of diphtherial antitoxin by rectal injection instead of subcutaneously. He has used this method in twenty cases, and believes that the fluid is easily and quickly absorbed. The bowel is first washed out by a simple enema, and then by means of an ordinary enema syringe and a gum-elastic catheter of medium size and about twenty centimeters long, the serum is introduced into the rectum. The method causes neither pain nor any unpleasant effects. The curative effect seems to be as certain as when the antitoxin is given by hypodermic injection. There is no need, so far as Dr. Chantemesse's experience goes, for any increase of dose when the serum is administered by the rectum. In severe cases of erysipelas he has injected into the rectum 200 to 300 cubic centimeters of the Marmorek serum. This quantity was readily absorbed and caused no ill effects. In applying this serum locally he adds five parts of lanolin to one part of the serum; pain, swelling and redness are thereby greatly reduced.

Are the Failures in Treating Hypertrophied Prostate with Castration always Reported. Czerny, of Heidelberg, doubts it. His experience in three cases has been that it was not followed by improvement, but rather by a series of ills, and it is a serious matter for a surgeon to cripple his patient in this way, without the slightest benefit to him. It is scarcely two years since Hegar's "Castratio Muliebris" to reduce myoma, was transferred to the male to reduce the prostate, which is so much less intimately connected with the spermatica interna than the uterus in the female. In that time White has collected 111 observations, and Bruns in the *Mitt. u. d. Grenz. der Med. und Chir.*, Vol. 1, No. 1, has stated the results of 148 observations, with a large number permanently freed from their pro-

vious inconveniences and 23 deaths. Czerny comments that at least the patient should be fully warned, and he hopes that the contraindications will soon be more definitely established. In cases of myoma of the prostate, or excessive development of one part, Bettini's galvano-caustic incision into the prostate is to be preferred as castration would probably have little effect on the flow of urine. This operation in the hands of a skillful operator, with a good apparatus (*Langenbeck's Archiv.* Vol. xxi, No. 1.) Czerny believes is destined to prove a blessing far more than is generally accepted at present.—*Dtsch. med. Wochsch.*, April 16.

Care of the Ear During the Exanthemata.—Dr. Walker Downie, of Glasgow, writes to the *Journal of Laryngology, Rhinology and Otology* regarding 400 cases of otitis media in children, the cause of which in about 60 per cent. was fairly determined to have been measles, scarlet fever, whooping cough, mumps or teething. From the very beginning of the illness, where there are any catarrhal symptoms, the patient should be directed to use the handkerchief frequently and strongly, the object being to clear the nose and nasopharynx of mucopurulent products, and to prevent them from settling and decomposing around the Eustachian orifices, through which infection of the ears takes place. If the child can not do this effectually the Politzer inflation bag should be used. The quantity of secretion dislodged and thrown into the mouth by this means is astonishing. When there is dullness of hearing or pain in the ears, resort to inflation should never be delayed. When the pain in the ears is acute, and should immediate relief not be obtained from inflation, and especially if there is a sudden rise of temperature without other explanation, the tympanum should be punctured without delay. Have the head securely held; have the membrane brightly illuminated; use an arrow-shaped paracentesis knife with a shoulder; puncture the tympanic membrane in its lower and posterior part. The operation not only relieves the immediate pain, but saves the deeper structures of the ear and prevents the misery of a chronic otorrhea with its attendant risk.

Treatment of Heart Troubles During and After Pregnancy.—According to Phillips in the *Revue des Mal. des Femmes*, for January, the different forms of cardiac lesions to be apprehended are: 1, adhesions due to an old pericarditis, or displacement of the heart from pleural adhesions; 2, myocarditis and degeneration of the cardiac muscle; 3, endocarditis affecting the valves; 4, endocarditis in an acute form, grafted on a chronic form. During pregnancy, if there is no symptom of cardiac insufficiency, it is enough to forbid going up stairs, and to keep the digestive functions in good order. The disorders indicating that the lesion is no longer compensated, do not appear before the fifth month, after which the patient must be kept in a reclining position. Arsenic, iron and strychnin will combat the weakness of the heart; ether and ammonia in case of syncope. If there is edema and dyspnea, digitalis and strophanthus can be given, even in cases of aortic lesion. During labor the dyspnea is less if the patient sits, and the dyspnea may necessitate injections of ether, or even the premature rupture of the membranes before the dilation of the neck is complete. Delivery must be hastened, and forceps used as soon as the dilatation of the neck is complete. An anesthetic must be employed, preferably ether. During the extraction, it will be well to lay on the abdomen, a bag of sand weighing about a dozen pounds, to avoid the abrupt drop of the blood pressure in the abdomen. That after delivery is the most dangerous period, and it lasts four days. Hemorrhages are not to be feared, but rather encouraged, and the threatening symptoms are due to the distension of the right side of the heart. No ergot nor injections of ergotin can be permitted at all, but amyl nitrite is theoretically indicated, and gives good results in practice. Subcutaneous injections of ether and strychnin

are very useful. In certain serious cases abortion has been advocated, but Phillips opposes this, as it is often followed by immediate death.—*Revue Int. de Méd. et de Chir.*, April 10.

Stypticin.—Gottschalk in *Therapeutische Monatshefte* records the results of the use of this drug in forty-seven cases of bleeding from the uterus. Stypticin is a yellowish powder, readily soluble in water, it is a hydrochlorid of cotarnin, one of the oxidation products of the opium alkaloid narcotin: in chemical structure it is closely allied to hydrastinin. It can be given subcutaneously, or more conveniently in powder or gelatin perles. The earliest experiences of its employment were not favorable, owing to too small a dose being given. Gottschalk finds that 0.05 gm. can be taken five or six times a day without any evil results. It has a great advantage over hydrastis and other uterine hemostatics, in that, as might have been expected from its source, it possesses a well-marked and potent sedative action which is both local and general, and hence specially indicates its use in dysmenorrhœal affections. Stypticin checks promptly hemorrhage resulting from pure uterine subinvolution, that is, that due to muscular atony and not to retention of membranes, etc. In cases arising from the latter cause ergot and hot douches together are better. In fungous endometritis stypticin is a valuable adjuvant to the curette; it is very useful when the patient objects to curetting, and particularly those cases in which this treatment does not stop the hemorrhage. It is also useful in bleeding caused by fibroids or the climacteric. In hemorrhage secondary to parametritis or diseases of the appendages it is less effectual than hydrastis. In such cases, however, idiosyncrasy is usually marked, and a cure is often not effected till the changes have been rung on all the various hemostatics. In purely congestive menorrhagia it is well combined with hydrastis. Stypticin is powerless to control the bleeding of uterine polypi, and is contraindicated in threatened abortion, or indeed in any of the hemorrhages of pregnancy, as it has a marked power of stimulating uterine contraction. This may be induced by it directly or result indirectly from the anemia produced by its vaso-constrictor action.

Hospital Notes.

HOSPITAL FOR CHILDREN AT PITTSBURG.—Henry C. Frick, chairman of the Carnegie Steel Company, will build a hospital for children on Squirrel Hill, Pittsburg, Pa., within a year, to cost \$500,000. The building will be on a plot of forty acres, which will be transformed into a private park and flower garden. The hospital will be placed under the control of the Protestant Episcopal Church.

THE NEW ST. JOSEPH'S HOSPITAL BUILDING in Joliet, Ill., was dedicated May 7 with elaborate ceremonies. St. Joseph's Hospital is a model institution, and is valued at \$70,000, and has a capacity for 125 patients.

ONE HUNDRED AND FORTY-FIVE YEARS OLD.—The one hundred and forty-fifth annual meeting of the Philadelphia Contributors to the Pennsylvania Hospital was held in the library room of the institution May 4. Frederick Fraley was called to the chair, and Arthur Biddle, counsel for the hospital, was appointed secretary of the meeting. The annual report of the Board of Managers was read, giving an account of the work and progress of the hospital during the past year.

Detroit.

AT THE REGULAR MEETING of the Detroit Medical and Library Association, May 11, Dr. J. Flinterman presented a paper entitled, "Degeneration."

THE WAYNE COUNTY MEDICAL SOCIETY, at its regular meeting May 14, inspected Elosie and Wayne about forty strong. At Elosie, Dr. E. O. Bennett, Superintendent of the Asylum, had them shown through the asylum, and partake of a luncheon, after which he sent them on their way rejoicing, in private and public conveyances, to Wayne, about two miles dis-

tant, where in the evening, at the Methodist Episcopal church, the regular weekly meeting was held. The program was as follows: Dr. R. H. Honner, "Intestinal Antiseptic in Typhoid Fever"; Dr. A. D. Holmes, "Broncho-pneumonia in Children"; Dr. E. F. Stewart, "Commercialism in the Practice of Medicine"; and Dr. E. B. Smith, "Surgical Treatment of Wounds." After the meeting, Mrs. S. A. Morrison, widow of the late Dr. Morrison, tendered a reception and banquet at her residence to the members of the society.

HEALTH OFFICE REPORT for week ending May 16: Deaths under 5 years 47, total 103; births, male 49, female 57, total 106. Contagious diseases: Diphtheria, last report 12, new cases 9, recovered 4, died 1, now sick 16; scarlet fever, last report 28, new cases 6, recovered 6, died none, now sick 28; measles, last report 1, new cases 1, recovered 2.

Louisville.

KENTUCKY MEDICAL ASSOCIATIONS.—The Southern Medical Association held its third semi-annual meeting at Russellville, May 12-14, with about eighty members and a number of visitors from Tennessee present. The following are the officers: President, Dr. D. G. Simmons, Adairsville; Vice-President, Dr. H. C. Cartwright, Bowling Green; Secretary, Dr. R. W. Frey, Trenton; Treasurer, Dr. C. G. Mosley, Casky.

THE SOUTHWESTERN MEDICAL ASSOCIATION held its twenty-fifth annual convention in Paducah, May 12-14. The following are the officers elected for the ensuing year: Dr. J. T. Reddick, Paducah; Vice-President, Dr. M. W. Rozell; Secretary, Dr. P. H. Stewart; Treasurer, Dr. C. H. Brothers. Dr. R. A. Hibbs, of New York, was made a life member, and eight regular members were added to the list.

UNDERTAKERS.—Complaint having been recently lodged with the mayor in regard to the lax way the undertakers have of obtaining signatures to death certificates, an order has been issued that they be compelled to comply with the law which requires all death certificates to be filed with the health officer before a permit for the burial can be had. This order was made to apply to the officials at the cemeteries who allow the burials to take place and trust the undertaker to see to the permit later. The case reported to the mayor was as follows: A death occurred in a prominent institution and the officials allowed the undertaker to attend to all the details. The burial took place and ten days afterward the attending physician to the institution thinking it queer that he had not signed the certificate investigated the matter and found that the death return had not been handed in, yet the burial had been allowed to take place at the cemetery. No such methods will prevail now.

COMMENCEMENT. The commencement season for the spring and summer medical schools is at hand, the Hospital College of Medicine and the Kentucky School of Medicine being schools of that character. The latter school will this year inaugurate the wearing of the regular university cap and gown, by both faculty and graduating class, an innovation which will prove popular and will no doubt be adopted by the other colleges in the course of time.

LOUISVILLE MEDICAL COLLEGE. Dr. A. M. Cartledge, formerly Professor of Surgery and Clinical Surgery in this college, has resigned this position to accept the chair of Gynecology made vacant by the retiring of Professor Ireland, who becomes Professor Emeritus of the same branch. Dr. W. C. Dugan has accepted the chair made vacant by the resignation of Dr. Cartledge.

Dr. J. M. Bodine, Dean of the Medical Department of the University of Louisville, has been the recipient of many congratulations on account of his election at Atlanta to the position of President of the American Medical College Association.

Dr. Todd. The many friends of Dr. Lyman Beecher Todd, of Lexington, will be sorry to learn of the sad accident which befell one of his daughters on the 13th inst. While out bicycle riding in an attempt to cross in front of an electric car she was struck and thrown under the car and almost instantly killed, the front wheels running over her chest.

THE PUBLIC SERVICES.

Army Changes. Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from May 8 to May 15, 1896.

Major H. O. Penley, Surgeon, granted three months' leave of absence, to take effect about July 1, 1896.

First Lieut. James M. Kennedy, Asst. Surgeon (Ft. Missoula, Mont.), ordered to Ft. Yellowstone, Wyo., for temporary duty with troops in the field, in the National Park, during the season.

PROMOTIONS.

To be Assistant Surgeons, with the rank of Captain, May 4, 1896, after five years' service: First Lieut. William F. Lippitt, Jr., Asst. Surgeon; First Lieut. Merritt W. Ireland, Asst. Surgeon; First Lieut. George M. Wells, Asst. Surgeon.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending May 16, 1896.

Medical Inspector R. A. Marmion, detached from the "Newark," ordered home and placed on waiting orders.

Surgeon L. B. Baldwin, detached from the "Cincinnati" and ordered to the "Newark."

Surgeon N. H. Drake, detached from the "Franklin" and ordered to the "Cincinnati."

P. A. Surgeon I. W. Kite, detached from the naval hospital at New York and ordered to the "Franklin."

P. A. Surgeon P. Leach, detached from the naval laboratory, New York, and ordered to the naval hospital, New York.

Medical Inspector R. A. Marmion, ordered as member of the board of inspection and survey June 3, and member of medical board, navy yard, Washington, D. C.

Medical Director W. K. Van Reypen granted three months' leave of absence from June 3, with permission to leave the United States.

Marine-Hospital Changes. Official list of changes of station, and duties of Medical Officers of the U. S. Marine-Hospital Service, for the fifteen days ended April 30, 1896.

Surgeon R. D. Murray, granted leave of absence for four days, April 30, 1896.

Surgeon J. B. Hamilton, granted leave of absence for fourteen days, April 21, 1896.

Surgeon G. W. Stoner, detailed to represent Service at meeting of American Medical Association at Atlanta, Ga., April 29, 1896.

BOARDS CONVENED.

Boards for physical examination of candidates for appointment in revenue cutter service:

At Philadelphia, Pa., Surgeon George Purviance, chairman, and P. A. Surgeon G. T. Vaughan, recorder, April 22, 1896.

At San Francisco, Cal., Surgeon John Godfrey, chairman, and Asst. Surgeon Rupert Blue, recorder, April 28, 1896.

At Washington, D. C., P. A. Surgeon C. E. Banks, chairman, and Asst. Surgeon W. J. S. Stewart, recorder, to convene May 1, 1896.

Change of Address.

Bryan, J. C., from 367 to 351 48th Street, New York, N. Y.
Carman, E. T., from 2400 Paulina Street to 3210 Malden Street, Chicago.
Flske, G. F., from Chicago Opera House Bldg., to Room 612 Reliance Bldg., Chicago, Ill.

Hammond, J. C., Omaha, Neb., to Denison, Iowa; Harrison, W. K., from 52 Walton Place to 32 Delaware Place, Chicago, Ill.; Houston, James, from Detroit, Mich., to Ingersoll, Ont. Canada.

Krieger, Geo., from 6302 S. Halsted Street to 3242 Vernon Ct., Chicago.
Langer, C., from 7115 Cottage Grove Ave., to 7137 Laugley Ave., Chicago, Ill.

MacDonald, C. E., from New York, N. Y., to Liberty Falls, N. Y.
Packard, J. H., from Philadelphia to Denver, Chester Co., Pa.; Potts, C. N., from Colorado Springs to Silverton, Colo.; Patch, Wm., from Irving to Cooksville, Ill.

Roberts, A. Sydney, from Philadelphia to Bala, Pa.; Raudebaugh, E. C., from Overton to New Pittsburg, Ohio.

Stowell, J. H., from Reliance Bldg., to Suite 907 Columbus Memorial Building, Chicago, Ill.; Spinney, C. N., from New York, N. Y., to 47 Montcalm Street, E., Detroit, Mich.

Thomas, C. P., from Everett to Spokane, Wash.

ADDRESS.

ADDRESS OF THE CHAIRMAN OF THE SECTION ON SURGERY AND ANATOMY.

Delivered at the Forty-seventh Annual Meeting of the American
Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY C. A. WHEATON, M.D.
ST. PAUL, MINN.

Gentlemen of the Surgical Section:—Through the agency of our worthy secretary we have been enabled to provide a program of rare promise for the ensuing three days. Custom has established that the presiding officer of the Section on Surgery shall offer some contribution to its proceedings. Such are usually of a scientific character. I believe, however, that fully as much benefit may accrue from a résumé of the needs and obligations of the workers in this department of our ASSOCIATION. In my humble opinion, at a time when the scientific attainments of the representative members of this ASSOCIATION were of a much more mediocre quality, when they met together in general session and deliberated upon the requirements of the profession, and before the days of the segregation of this ASSOCIATION, before the epoch of specialties, these meetings meant something, and much of good immediate and remote resulted. Memory recalls the time when the elder Warren, the elder Gross, Valentine Mott, Pancoast, Rhea Barton, Brainerd, Hodggen, Bigelow and many others of international fame attended these meetings and shed the radiance of their brilliant intellects upon these National gatherings, and the actively working members of the profession at large, who represent the brain and sinew of the American profession, attended regularly with alacrity and enthusiasm, with insatiable appetites to assimilate all that was good and practical that emanated from these master minds. The older members were strengthened, the younger encouraged by their example to renewed efforts. In those days we learned by attrition how little we knew, and how great the magnitude of the possibilities of the future, when so directed. We have our modern Goliaths; we have Senn and Fenger, Cheever and Warren, McBurney and Bull, Wyeth, White, Keen, Morton and Roswell Park, who have all placed indelibly upon the records of this corporate body an inscription which will endure forever; many of whom too often absent themselves from these meetings, depriving us of the benefit of their superior genius and accomplishments. This unfortunate condition of affairs is the logical result of that segregation which I so much deplore. We are individually and collectively proud of the attainments of the AMERICAN MEDICAL ASSOCIATION. We know that by comparison with similar organizations the world over, we do not suffer. This statement needs no defense and is, I believe, conceded, but that a house divided against itself can not

stand, is as true to-day as when spoken centuries ago. We must bring these wanderers back into the fold or our ASSOCIATION will suffer in numbers, influence and proficiency, and the time is not far distant when the AMERICAN MEDICAL ASSOCIATION will be secondary to other organizations, or extinct. I earnestly deprecate this condition of affairs, because it deprives us in our deliberations of the aid of the other members of our profession, whose efforts for the conservation and preservation of life have nothing to do with the knife except in a passive sense, but whose counsel we need, and whose assistance often is absolutely essential in guiding our precious charges to a safe harbor. Where will we land if these leaders in surgery and in medicine, in gynecology and the various other specialties, hold themselves aloof from these gatherings? Sir Edward Jenner gave us vaccination, Morton, Wells and Duncan gave us anesthesia, and Lister a knowledge of surgical cleanliness. We younger men of the present generation felt that we were approaching the surgical millenium with those adjuncts at our command. The surgical license which has resulted has led us into many excesses in surgical procedure. Only a few short years have elapsed since nature's bountiful resources for the protection of human life were revealed, and we are now experiencing the reaction which is an unavoidable consequence of riper experience. Instead of the asexualization of our suffering sisters, we are groping along conservative lines, endeavoring to preserve the organs and functions with which God and nature endowed her. Let us preserve rather than destroy. May we not again invoke the assistance of our absent brethren whose counsel and advice we so much need? The major part of our program is made up of a symposium on the injuries of the cerebro-spinal axis and its bony encasement. I feel confident the subject will be amply covered and fully discussed. It is my earnest hope that in its medico-legal relations, it will receive the attention its importance deserves. The malodorous situation in which the medical witness so often finds himself is due to several causes, chief of which is the motive which inspires his testimony, the legal jugglery of an astute lawyer, and confined by the rulings of the court it compels him to answer "yes" or "no," thus preventing intelligent testimony, baffles justice, humiliates and makes the witness ridiculous in the eyes of both the jury and the public. Our corporations as well as medical witnesses have reason to regret the theories of Erichsen, so long accepted as true, which are now relegated to that professional mausoleum that contains so many entombed medical and surgical fallacies of the past, and by their fuller knowledge derived by scientific research. We now recognize as neurasthenia the Erichsen bugbear of railway spine. We followed the teachings of Erichsen for many years, blindly I think, and it is a question in my mind whether the modern substitute

neurasthenia is not a monster equally desperate and threatening, and which may prove to be another siren that may lead us to commit greater professional inaccuracies and entail greater humiliation. The question of the hour is (in this connection), what can we, as representatives of this body, do to remedy this admitted evil? I, for one, believe that equal justice to both plaintiff and defendant will not obtain until such time as the so-called expert is placed by statute beyond the influence of monetary considerations. I sincerely hope that the many able papers about to be presented before this Section and the resulting discussions will elucidate an intelligent solution of this vexed question of medical ethics.

In conclusion, I do not wish to be understood as disparaging one's individual evolution in a special line, for God knows we are all weak enough in any of them, but with a view of maintaining the integrity of this ASSOCIATION, and particularly the Surgical Section, for it is an important integral part of the whole, and its life and future usefulness depend upon the hearty coöperation of the pioneers who have hewn the way, and made it possible for the younger and less experienced to follow and participate in the formation of a professional fabric which will be a credit to our leaders, add to the laurels of the American profession, and amalgamate and strengthen this organization. I venture to say that there is not a successful specialist in any branch to-day, who is not in a large measure dependent upon his "general medicine" brethren for his following and success, and if my premises are correct he is obligated to attend these gatherings, participate in their labors and reap the benefits justly earned. If he is a man of stout heart, a good campaigner, and has a large income, he may be able to attend all the other association meetings, but to this one he should pledge his special fealty because of its National character, because of its cosmopolitan personality which makes us feel so interdependent, and finally because the character of work done by this Section reflects, in a large degree, the quality of the whole.

ORIGINAL ARTICLES.

SUBPHRENIC ABSCESS AND ITS RELATION TO PYOTHORAX.

Read in the Section on Surgery and Anatomy at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY CARL BECK, M.D.,

PROFESSOR OF SURGERY, NEW YORK SCHOOL OF CLINICAL MEDICINE; SURGEON TO ST. MARK'S HOSPITAL, GERMAN POLIKLINIK, WEST SIDE GERMAN DISPENSARY; CONSULTING SURGEON H. S. G. S. ORPHAN ASYLUM, ETC., NEW YORK.

Among five cases of subphrenic abscess which I observed during the last six years, I could but twice make a correct diagnosis before operation. In two cases I diagnosed pyothorax, the symptoms being those made known by the more or less exhaustive descriptions of modern writers. From the study of the current literature on this subject, as well as from the reports of friends I know, however, that I do not assume an isolated position in this connection, and that pyothorax is very often confounded with subphrenic abscess—not unfrequently even after operation. Such errors impressed me gravely with the important necessity of widening our limited diagnostic knowledge upon this neglected subject. Practically this error, especially if made by a surgeon, is no great misfortune for the patient. It differs but little

whether the abscess is located above or below the diaphragm, as the essential part of the treatment in either condition is the same, namely, free opening. But manifestly from a scientific standpoint it is most desirable to know before the operation, whether pyothorax or subphrenic abscess is present.

Increased knowledge would certainly awaken the interest of the profession much more closely upon this Proteus-like disease. When recognized at its earliest possible stage it will give the surgeon most favorable possible chance for success. It will not then happen that patients who might be easily saved by the surgical knife, will be treated for tuberculosis pulmonum until the autopsy reveals that they succumbed to a pus collection in the subphrenic space.

I may even venture so far as to maintain that subphrenic abscess now takes the rank of appendicitis of yore, when an occasional autopsy demonstrated that under extremely rare circumstances perforation of the vermiform appendix, caused by "the obligate grape-seed," may occur, "a cure in such unfortunate cases of course being out of question."

Great was the change that such a short time brought forth! While experienced surgeons had seen one or two such cases during their lives, the leading surgeons of to-day count their cases by the hundreds. Is this due to appendicitis now being a more frequent disease than formerly? Probably not. It is the extensive knowledge gained particularly through the efforts of American surgeons by their autopsies *in vivo*.

As soon as the profession at large will take the same interest in subphrenic abscess as they do now in appendicitis the number of cases, which in the whole present literature amounts to less than two hundred, will rapidly swell to an enormous number and accordingly the prognosis, except in those of malignant origin, will be most favorable.

The history is a most important guide in differentiation. In subphrenic abscess there is generally a history of previous abdominal disturbance. There is no history of cough and expectoration, as in pyothorax. The heart is little; if at all, displaced and there is no excessive action of the thorax or of the intercostal spaces. In the lungs, vesicular breathing is found below the clavicle. Pectoral fremitus is also clearly perceptible. There is a well-marked limit to the region of vesicular breathing, below which the expiration-murmur is replaced by amphoric sounds. Deep inspiration pushes the boundary line of the region of vesicular breathing much farther down, into areas in which formerly no respiratory murmur could be perceived. This would indicate a well-marked separation between the lungs and the abscess cavity, the boundary line of the lungs protruding toward the abscess cavity during deep inspiration.

It is sometimes impossible to distinguish an encysted pyothorax from a subphrenic abscess. The pathognomonic signs of such effusions urged by Leyden were absence of cough and slight expectoration, slight displacement of the heart and rapid change of note if the patient is rapidly turned. But, according to my observations, pleuritic effusion, particularly pyothorax, sometimes occurs without these symptoms.

The motions of the exploratory needle introduced into the abscess, were also regarded as pathognomonic by Fuerbringer. But, bearing in mind that in subphrenic abscess the function of the diaphragm is greatly impaired and that, furthermore, the point of the exploratory needle may be fixed by the diaphragm

as well as by the abscess membrane, neither the presence nor the absence of the motions can be regarded as determining pathognomonic factors.

If the diaphragm, being pushed up high, tightly adheres to the thoracic walls the needle may invade the subphrenic abscess without being fixed by the diaphragm: consequently, even if the diaphragm should still be able to make respiratory movements, the needle would not necessarily be moved by them.

The value of Litten's diaphragm-phenomenon is not yet established. Jendrassik asserts his ability to note a well-marked concave undulating curve parallel to the costal margins in the manumary as well as the axillary line during inspiration. In one of his cases he based the diagnosis of subphrenic abscess upon this phenomenon. The correctness thereof was demonstrated by subsequent operation.

Pfuhl recommended manometry of the internal pressure of the abscess as a reliable guide for differentiation between pyothorax and subphrenic abscess. The canula of a trocar after being introduced into the abscess cavity is brought into connection with a manometer, so that the motions of its mercurial column can be registered. If the canula be in the thoracic cavity the canula would fall during inspiration and rise during expiration, while, if the canula be in the subphrenium, the column would rise during inspiration and fall during expiration. This phenomenon would be due to the dilatation of the pleural cavity and to beveling of the contracting diaphragm. So the conditions of pressure in the subphrenium would be inversely proportionate to the pyothoracic cavity; but regarding the fact, that in all cases except those of very recent date the contractility of the diaphragm is greatly impaired, if not totally annulled, by over-extension as well as by permanent absorption of toxic products, it can hardly be expected that it still possesses power sufficient to increase the pressure in the subphrenic space and to diminish it in a pyothoracic cavity.

Jaffé simply advises controlling the velocity of the pus as it flows through a trocar canula and to observe the difference in the amount of pus discharging during expiration and inspiration. If the amount were smaller during expiration the pus collection would be situated below, if during inspiration, it would be above the diaphragm; but for the same reasons as given for the Pfuhl experiments, these ingenious suggestions are unreliable.

All these points go to show that, aside from the history, there are but few absolutely reliable pathognomonic data for the diagnosis of subphrenic abscess. Practically, however, the main question will always remain as to the presence of an abscess. Whenever suspicion exists the introduction of the exploratory needle is a matter of course. The same aseptic precautions should be observed as in any other operation. The skin of the patient, as well as the hands of the surgeon, should be rendered clean, and the syringe and needle thoroughly sterile. If the first trial be negative, the needle should be introduced several times into different portions, as the pus cavity may either be of small extent or may contain a cheesy accumulation, or finally, may be divided into several small minor cavities by adhesions.

In the first event the cavity may be missed altogether by the exploratory needle, and in the second

the needle being introduced into the solid cheesy mass, can draw no pus. After each negative result, therefore, a wire should be pushed through the needle (which must not be of too small a caliber). Thus, some pus which had remained adherent to the inner surface of the needle, will become attached to the wire. Occasionally it will be useful to fill the syringe with sterile water after the operation, and force the water through the needle into a Petri dish. In case cheesy masses are present, small particles are sometimes drawn into the caliber of the needle which can not be seen by the unaided eye; but which, by being mixed with the sterile water, can be recognized under the microscope. In case the microscope does not give sufficient information resort should be had to cultures of the fluid.

T. Brown, in a case of subphrenic abscess, which he took for pyothorax until after operation, found cultures of the bacillus coli communis in the aspirated pus. He very properly emphasizes that when pus from this region yields on culture a mixed or pure growth of bacillus coli communis, there is a strong probability that the point of suppuration is situated below the diaphragm.

The treatment of subphrenic abscess, as alluded to above, is practically the same as that of pyothorax, that is, resection of a piece of rib, the subphrenic abscess generally being within the extent of the ribs. Only resection secures a sufficiently wide opening for thorough evacuation.

As a rule, the eighth, ninth or tenth rib, preferably in the median axillary line, is selected. If the abscess be large, in subphrenic abscess as well as in pyothorax, I have recently made it a rule to resect two or three ribs in order to be able to pack the whole cavity with gauze, which procedure seems to me to be the ideal treatment of any abscess. If the abscess be small, it will not generally be found within the axillary line; then the exploratory needle will always indicate the ultimate route of the incision line. Exceptionally such abscesses may be reached below the costal arches or the xiphoid process.

As to the question whether in the subphrenic abscess the pleuræ adhere or whether they present a cavity filled with serum or pus, it can be stated, that, although of great importance for prognostic purposes, it makes little difference in regard to the surgical proceedings indicated. It is still a widely accepted assumption, that if the pleural sac, when in a normal state, should be opened it would be exposed to the dangers of pneumothorax—not to speak of the erroneous fear of infection from the atmosphere or from escaping pus.

But it must not be lost sight of, that it really happens, as it did to me, that having diagnosed pyothorax the pleural sac is found empty, the abscess then, of course, being subdiaphragmatically located, the danger of pneumothorax is practically *nil*. In subphrenic abscess the diaphragm is then pushed so far up toward the thoracic cavity as to be pressed against the thoracic walls to a considerable extent so as to have its summit brought into permanent contact with the costal pleura. It may even have been so much overstretched as to be entirely paralyzed. The lower part of the thorax itself is also so much expanded that its aspirating power is diminished, and if it really should happen, that after the exposure of the pleural sac pneumothorax occur, and a feeble patient suffer shock, the final incision and evacuation may be deferred until the following day.

PERSONAL EXPERIENCE IN SPINAL SURGERY.

Read by title in the Section on Surgery and Anatomy, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY JOHN A. WYETH, M.D.

NEW YORK.

My personal experience with the surgery of the spinal cord embraces the following cases:

Case 1.—G. W. V., male, 31 years, April 19, 1888, while working at the bottom of an elevator shaft, the car descended upon him, striking the back of his head and shoulders, doubling him over forward with great force and producing fracture of the 11th and 12th dorsal and 1st lumbar vertebrae. He immediately became paraplegic, the bladder and rectum being involved in the paralysis. He was carried to his home and put to bed. November 1, more than six months after the injury, I examined him. He had some troublesome bed-sores in the region of the sacrum and hips and had been confined to his bed ever since the accident. I treated him by extension and plaster-of-Paris jacket, which he wore for more than a year. A zone of plaster-of-Paris, in which iron staples were inserted at three different and equidistant points, was placed tightly around the chest above and a similar belt below the line of fracture. Extension bars were then placed in the staples, which by key and ratchet were lengthened, thus forcibly lifting the superincumbent weight from the point of fracture. He improved gradually under the treatment and is now able to walk with the aid of a cane, but has a shambling gait and has not fully recovered the function of the bladder. He is still at times troubled with trophic sores over the sacrum. He is a pensioner on the list of the Western Union Telegraph Company, and does light work about the building in New York city.

It is impossible to estimate accurately the severity of the paralysis which occurred immediately after the accident. This was a case in which a suit for damages was under consideration, and I have noticed that without exception these cases consciously or unconsciously exaggerate their symptoms. However, there was a well-marked projection of the spines of the vertebrae at the seat of injury, and the persistence of the trophic sores and of the paralysis of the bladder even to this date, testify to a very considerable damage to the spinal cord, and it is more than likely that at the time of injury there was an extravasation of blood connected with the fracture, causing practically a complete paraplegia which in part disappeared by absorption of the clot, and by the support given to the part of the body above the point of fracture by the strong extension which was adjusted.

Case 2.—S. S., male, 9 years; admitted to Mt. Sinai Hospital, May 28, 1889. One week before admission he began to be paralyzed from about the level of the navel down. Complete paraplegia ensued. There was a slight dorsal kyphosis which had not been detected by his parents. Reflexes were absent. During suspension a Sayre jacket was applied, which he wore for three and a half months. September 18, I did a supra-public cystotomy for the relief of a severe cystitis, caused by frequent catheterization and infection.

As the paraplegia was in no way improved on Dec. 3, 1889, I removed the laminae of the fourth, fifth and sixth dorsal vertebrae. As the laminae of the fifth were removed, the dura was seen to bulge for an area about three-quarters of an inch in extent, and on opening at this point, a small round mass of cheesy-looking tubercular material was seen, partly within and partly projecting from the right posterior and lateral aspects of the cord. It was spherical in shape and less than three-quarters of an inch in diameter. It was carefully lifted out with the handle of a scalpel, and the surface of the cavity left was mopped out with a film of cotton wet with weak bichlorid solution. The boy was kept in bed in the recumbent position. February 1, two months after the operation the act of urination again became voluntary. By February 9

there were signs of motion in the legs and feet. By the 20th he walked well, from which time he continued to improve and has entirely recovered. Five years after the operation, when I last saw him, he could run, jump, dance, and do anything with his feet and legs.

Case 3.—G. D., male, 10 years; June 28, 1890, fell a distance of about twenty feet, striking upon the back, and became immediately totally paraplegic without at any time losing consciousness. The rectum and bladder were involved in the paralysis. For six weeks he was treated with a Sayre plaster-of-Paris jacket, but as he improved in no sense, he was brought to me for operation through the courtesy of Drs. Gibney, Watson and McLaughlin. He was in good general condition, but there was absence of motion from the level of the iliac spines down and no sensation from the junction of the middle with the upper thirds of thighs to the toes; there was also constant overflow of urine. There was no well marked kyphosis in this case, but from the line of motor paralysis it was decided that the seat of compression was near the dorso-lumbar junction.

Feb. 26, 1891, I removed the laminae of the 11th and 12th dorsal and 1st lumbar vertebrae. The dura when exposed and opened was greatly thickened and there was evidently a *chronic pachymeningitis*. The cord was pale in color, much diminished in size and soft to the touch; no direct compression by depressed bone was discoverable; the wound was closed as usual. The patient recovered promptly, but without any improvement, and died of gradual exhaustion in April, 1894, more than three years after the operation. In this case I am of the opinion that the crushing of the bodies was so slight that no deformity occurred. Extra-dural hemorrhage occurred producing compression and with the traumatism a *pachymeningitis* with permanent degeneration of the cord from pressure and anemia. The same condition resulted in the following case:

Case 4.—S. L., male, 16 years, in good health; fell January, 1894, striking on his back and head upon the floor. After three hours of unconsciousness, he realized that both lower extremities were paralyzed, as to motion and sensation. Rectum and bladder were also paralyzed. For several days after the injury he had chills or rigors, followed by high temperature. He was treated by his physician by careful attention to the bladder and bowels, nutritious diet, and the prevention of bed-sores, for six weeks after the accident, March 8, when he came under my care. He was seen by Dr. Sachs in consultation and it was found that there was complete loss of motion and sensation below the level of the 9th dorsal vertebra behind to near the umbilicus in front. The variations of the temperature in this case present an interesting study.

March 8, 6 A.M., 99.6; 9 P.M., 103.7. March 9, 6 A.M., 104.4; 8 A.M., 102.5; 11 A.M., 104.3; 12 noon, 103.5; 3 P.M., 104.7; 6 P.M., 102.2; 9 P.M., 103.5. From 9 P.M., March 9, it steadily declined and at 6 A.M., March 10, it fell to 97. By 3 P.M., it was 103.5. March 11, 12 and 13 there was little change from 101 to 103; March 14, it fell at 9 A.M. to 99.4; 15 and 16, about 99 to 100; 17, at 9 A.M., 101 to 102, a chill came on and the temperature rose rapidly to 104; 18 and 19, about 100; 20, chill, 103.4; 21, chill, 105; 22, 102 to 104; 23, 100 to 101, operation; 24, 102; 25, 100 to 104; 26, 101 to 105.8; 27, 101 to 105.8; 28, 100 to 104.8; 29, 101.5 to 103.3; 30, 102; 31, 97 to 102.2; April 1, 101 to 105.2; 2, 102 and fell to 100; 3, 101, at 3 P.M. it fell to 98, and by 5 P.M., was 103; 6, chill at 3 A.M., 103.4; 7, 99; 8, 105; 9, 101; 10, 103; 11, 101 to 103.8; 12, 99 to 100; 13, 100 to 101; 14, 6 A.M. chill, 102; by 3 P.M., 99; 15, 103.5, chill; 16, 9 A.M., 99; 6 P.M., 105.2; 17, 6 A.M., 103.3; at noon he died, temperature 102.

On March 23, I removed the laminae of the ninth, tenth and eleventh and part of the eighth dorsal vertebrae. Between the dura and the bones was a layer of lymph varying from one-eighth to one-fourth of an inch in thickness, which could be lifted off by carefully scraping with the dull scissors. This extended upward and downward as far as the canal was exposed. This membrane was like the rich plastic lymph which covers the intestinal peritoneum in some forms of

appendicitis. The dura was incised for four inches and a free quantity of cerebro-spinal fluid escaped. The cord was not bruised or divided, nor did it appear to have been injured in any way, but it was about one-half the normal size and paler in color. The patient rallied well from the operation. The variations in pulse and temperature which were present for three weeks before the operation persisted to the end. The urine for some weeks before the operation and after this was ammoniacal in odor and contained pus, necessitating irrigation every six to ten hours with warm Thiersch's solution. He gradually and steadily declined from the day of injury to April 17, the date of death. The wound healed without supuration. The cerebro-spinal fluid escaped from the wound in varying quantity to about six days before death, when the last drainage opening was closed. An autopsy was refused, much to my regret.

These two cases are unusual in my experience. In neither case was there an appreciable injury to the spinal column or cord. At the time of the accident there was evidently an extra-dural hemorrhage, due in all probability to the breaking loose of some of the veins which pass out from the bodies of the vertebrae posteriorly. This hemorrhage exercised a compression upon the cord for a considerable distance, gradually causing atrophy. The presence of the clot produced a pachymeningitis hemorrhagica externa, and the wide varying temperature resulted from this lesion. The cystitis which existed would not have caused such extremes of heat or rapid variations. Moreover the bladder was kept clear by irrigation.

Case 5.—Charles T., 10 years, of Newman, Ga., fell from a tree, a distance of about fifteen feet, in 1892, and suffered instant paraplegia. Four months after the injury he was brought to me. There was complete paralysis of motion and sensation from the level of the umbilicus down, including the rectum and bladder. The bladder did not overflow, but, when it was fairly distended with urine, his father had observed that by tapping with the finger on the abdomen just over the bladder, this organ would contract and empty itself of its contents in practically a normal manner. There was a recognizable projection of the spines above and below the seventh dorsal vertebra.

Removal of the laminae of the sixth, seventh and eighth dorsal demonstrated a fracture with laceration of the cord which was completely destroyed. No improvement followed the operation. The boy is still living, nearly four years after the operation, and is in good physical condition. His mind is more than ordinarily well developed with remarkable power of memory amounting in this direction to precocity. He still causes evacuation of the bladder by beating a tattoo over this organ.

Case 6.—H. A., male, 21 years, Sept. 1, 1889, was thrown from the cowcatcher of a locomotive on which he was riding, struck upon the rail and bounded from the track. He was picked up unconscious. When consciousness was restored he was paralyzed from his navel down, including the bladder and rectum. There were severe pains in the legs and feet.

April 30, 1890, I removed the laminae of the last two dorsal and first lumbar vertebrae. In crushing, the bones had impinged upon the cord, which was partly divided, and the undivided part was compressed between the laminae of the vertebra above and the crushed and displaced body below. Removal of the laminae relieved compression to a certain extent. When he recovered from the anesthetic, it was noticed that there was immediate slight improvement in motion, especially in the feet. This continued and now, in 1896, six years after the operation, he has

fairly good use of the lower extremities; can flex and extend thighs and legs and the anesthesia has disappeared above the knees. He uses one crutch and a cane and with these is able to get about. Within a year he came from his home, a distance of several miles unaccompanied, taking street cars and walking, to present himself at my request at the New York Academy of Medicine.

Case 7.—J. C., 31 years; Mississippi, April, 1893, while in good health, was shot by robbers: six pistol balls, 38-caliber, entered the body at short range and five of them lodged. The first missile passed through the alveolus of the left upper maxilla, wounded the tongue and lodged in the pterygo-maxillary fossa. This bullet I removed. The second ball fractured the right clavicle and was buried in the trapezius muscle and was also removed. The third bullet struck the skull at the occipital protuberance and remained lodged in the muscle at the back of the head and neck. A fourth missile struck a rib and again left the body. A fifth lodged in the deep muscles of the back. At the sixth shot he fell, conscious but paralyzed in the lower half of the body. This ball passed through the skin of the back two inches to the right of the spinous processes, and entered the spinal canal through the right laminae of the third and fourth dorsal vertebrae. Nov. 20, 1893, over six months after the injury, I saw this patient. There was complete muscular and sensory paralysis below a line starting near the sixth dorsal spine and passing parallel with the ribs to near the ensiform cartilage of the sternum. The bladder and rectum were also paralyzed.

Nov. 22, 1893.—Operation, during which I tracked the bullet to the spinal cord. It entered, cutting a plug out of the right laminae of the third and fourth dorsal vertebrae. A rim of lead was found adherent to this hole of entrance. The bullet passed forward, cutting the dura on the right side and the right portion of the cord, and passed beyond reach into the body of the vertebra just in front. Several spiculae of bone were found in the cord, and these had destroyed that portion not divided by the missile. The patient recovered from the operation in no way improved, excepting by the removal of the bullet from the nasopharynx and died about seven months after the operation from exhaustion due to bed-sores, cystitis and interference with the alimentary canal.

Case 8.—S. E. R., private, Troop "C," Third U. S. Cavalry, 20 years; June 19, 1895, while in the act of diving in Lake Champlain, struck violently upon his head and suffered immediate paraplegia. On being taken from the water he was found to be paralyzed as to motion and sensation from the diaphragm down. The paralysis also involved the region of distribution of the ulnar nerves, and the rectum and the bladder.

July 7 he was brought to Fort Columbus, where I saw him in consultation with Major John Van R. Hoff, Surgeon, U. S. A. The injury was located between the seventh cervical and the fourth dorsal, and it was very probable that the bodies of these vertebrae were crushed. Operation was not deemed advisable in this case as there was little doubt that the cord had been destroyed at the time of the injury, and that too long a period had elapsed to justify the hope of relief. The usual trophic bed-sores over the sacrum appeared. The patient was discharged from the service in December, 1895, and is now an inmate of the Soldier's Home in Washington city. His general condition remains unchanged.

Case 9.—L. S., 16 years, personal and family history negative, Oct. 7, 1895, fell one flight of stairs, striking on right sacral region; could not get up but was not unconscious. Admitted to Mt. Sinai Hospital Oct. 9, 1895.

Examination showed a projection over the spine of the seventh cervical vertebra. Head was held stiff and rigid. All voluntary motion of the lower extremities and lower portion of trunk, including bladder and rectum, suspended; was able to move arms, but not without great difficulty; anesthesia from level of the lower portion of the scapula down, and down

the inner side of both arms, ulnar distribution. Reflexes suspended. On the day of admission, October 9, the pulse varied from 40 to 52; respiration, 20; temperature normal. October 10, pulse 56 to 75; respiration 18 to 24; temperature, 99 to 104. October 11, pulse, 42 to 80; respiration, 11 to 34; temperature varying from 96.6 to 104 degrees. October 12, pulse 30 to 98; respiration 9 to 16; temperature 91 to 95.2 degrees.

The disturbance in body temperature and in the respiratory and circulatory centers, which is not uncommon in these cases of injury of the spinal cord and membrane, may be observed in the following record of this case for the third day after admission:

Oct. 12.	Temp.	Resp.	Pulse.
1 A.M.	96	12	42
3 A.M.	95.8	12	44
5 A.M.	93	14	46
7 A.M.	92.5	16	98
8 A.M.	90.8	14	45
10 A.M.	92	9	42
12 Noon	91.8	10	36
2 P.M.	91.8	9	30
4 P.M.	91.8	9	30
6 P.M.	92.4	20	35
8 P.M.	93.6	9	36
10 P.M.	94.9	9	38
12 Midnight	95.2	10	43

October 13 the pulse never went above 48 and was as low as 42; respiration, 10 to 21; temperature, 95.4 to 100.8. October 14, pulse, 45 to 55; respiration, 14 to 21; temperature, 100.2 to 101.4. October 15, highest temperature was 101.3, and lowest 99.8; respiration, 13 to 18; pulse, 42 to 50.

There was scarcely any variation from this condition until after October 20, when the temperature rose to 103, respiration, 15 to 20; pulse, 45 to 55. About the same on the 22d and 23d. Again on the 26th the temperature rose to 103, and never got lower than 101; pulse, 50 to 70; respiration, 18 to 20. From this time on the pulse began to grow very rapid and was 70 to 86 on October 31. On November 1, 2 and 3 it was as high as 96 beats to the minute; respiration on these days was from 24 to 28; highest temperature, 104.6.

There is nothing further of interest in this case. The patient is still living and has complete paraplegia from the level of the apices of the scapulæ. The usual bed-sores due to trophic disturbance, are present over the sacrum. The fracture was due to contre-coup, the patient striking only on the sacrum.

Case 10. W. W., 27 years, of Rockaway, N. Y., a laborer in good physical condition. Aug. 3, 1895, while leaning well forward, he was struck over the spines of the tenth, eleventh and twelfth dorsal vertebrae by a stone weighing about twenty pounds, as estimated, which fell from a height of about ten feet; he fell to the ground, having become instantly paralyzed in both lower extremities.

August 11, eight days after the injury, having seen the patient in consultation with Drs. Stephen Pierson and J. H. O'Reilly, of Morristown, N. J., I removed the laminae of the tenth, eleventh and twelfth dorsal vertebrae. Some fragments of the laminae had been driven down upon the dura, but had not perforated its membrane, only mashing and bruising the spinal cord, which was not, however, entirely severed; there was no hemorrhage within the dura, which was immediately closed by interrupted sutures of fine sterile catgut. At the time of operation there was complete paralysis of motion in both lower extremities and of the bladder and rectum. The line of anesthesia extended in the arc of a circle about six inches below the umbilicus in front and about the same level posteriorly. The third day after the operation the patient believed there was improvement in motion,

and was able to move the foot of the right side, which he could not do before. This improvement, however, was only temporary, for in a letter, dated April 19, 1896, from Dr. F. W. Flagge, who had charge of the patient, he says:

"Walton thinks there has been some improvement in motion, but I doubt it. His feet and ankles swell during the day, but this disappears by morning. His legs jump when touched, the knees jerking together; there are stinging sensations at times in the thighs and legs, and pain shoots down to the toes, beginning at the calf of the leg. He also suffers from inflammation of the bladder. The urine does not overflow now, all the time, as it did at first; sometimes as much as two hours elapse without any coming away, then it comes in a spurt in no way controlled or controllable by the patient. Pulse, 96 to 104; temperature, normal; respiration, 20; skin cool and moist; has lost weight. Large bed-sores formed on the prominences of the sacrum, but those are healing. Severe priapism occurs every day; bowels respond to cathartics in large doses, and he has the usual sensations in the bowels after taking medicine but has no feeling in the rectum."

Case 11.—J. H., 19 years; physical condition excellent. Aug. 12, 1895, while sitting on the railing of a porch, it broke and he fell backward about eight feet, striking directly upon the head, causing violent acute flexion of the chin upon the chest. He remained motionless, and when picked up by the by-standers screamed with pain. He was seen within a few minutes of the accident by Prof. Richard Douglas, of Nashville, who found every evidence of profound shock, rapid pulse, shallow respiration, extreme pallor; he was perfectly conscious and complained of intense pain in the back of the neck, which was greatly increased by the slightest motion. There was complete paralysis of both motion and sensation in the trunk and both lower extremities, the line of anesthesia being one inch above the level of the nipple. The right arm was partially paralyzed, with complete anesthesia in the distribution of the ulnar nerve. Prof. Duncan Eve saw the case in consultation. There was a decided depression over the region of the fifth cervical, and a diagnosis of fracture of the cervical vertebrae, probably the fourth and fifth, with pressure on the laceration of the cord, was made. The patient was placed upon a hard mattress and extension made from the chin and occiput, counter-extension being made by elevating the head of the bed: an ice-bag was applied over the seat of the injury. There was marked elevation of the temperature in a few hours and a great thirst, severe constipation and incontinence of urine.

Through the courtesy of Drs. Douglas and Eve I was called to this case, arriving on the morning of August 16, four days after the injury. Since that date the line of anesthesia had extended to three inches above the level of the nipple, and in the left arm paralysis of motion was appearing. The steadily ascending involvement of the cord already encroached upon the roots of origin of the phrenic nerves and convinced me that death would result in a very few days by extension of paralysis, and that, however hopeless operative interference might be, it was all that was left to be advised. The condition was clearly explained to the parties in interest and operation was accepted.

With the assistance of Drs. Douglas and Eve and the staff of Dr. Douglas's private hospital in Nashville, to which the patient had been carried, I performed the operation of laminectomy, removing the spines and laminae of the fourth, fifth and sixth cervical vertebrae. The fifth was found to have been fractured on both sides close to the origin of the lamina from the body of the vertebra, and again fractured near the junction of the two laminae or bifurcated

spine. One side of the fractured lamina had been driven forcibly upon the substance of the cord, crushing and almost completely dividing it at the level of the body of the fifth cervical, without penetrating the dura. The dura was opened, the cord was found to be pulpified but there was no hemorrhage within the membranes.

The patient bore the operation well; no evidence of shock. The temperature six hours after the operation rose to 105. No improvement followed and no material change took place until the sixth day after the operation. The patient then developed well-marked hypostatic pneumonia and died from respiratory failure on August 24, twelve days after the injury and eight days after the operation.

The temperature, pulse and respiration ran as follows:

	Tempera- ture.	Pulse.	Respi- ration.
First day. . .	100 to 104.2	120 to 75	28 to 16
Second day. . .	103.3 to 102.1	120 to 100	22 to 16
Third day. . .	103 to 99	100 to 80	20 to 13
Fourth day. . .	103 to 101	90 to 80	20 to 22
Fifth day ¹ . . .	104.3 to 102	114 to 100	22 to 32
Sixth day. . .	104 to 100	104 to 112	19 to 18
Seventh day. . .	100 to 104	104 to 92	15 to 24
Eighth day. . .	101 to 104	80 to 100	15 to 28
Ninth day. . .	101 to 105	80 to 96	24 to 34
Tenth day. . .	103 to 104	88 to 96	28 to 34
Eleventh day. . .	103 to 104	88 to 96	24 to 36
Twelfth day. . .	102 to 105	88 to 90	40 to 30
Thirteenth day	105 to 107.2	86 to 120	27 to 40

Patient died at 2:40 P.M.

It is evident that interference with the function of the phrenic nerve was present in this case from the moment of injury. The filament of the fifth cervical nerve which goes to the phrenic, was involved by the fracture. The ascending degeneration of the cord involved in succession the fourth and third cervical, ultimately producing paralysis of the phrenics, thus impairing respiration and inducing hypostatic congestion of the lungs.

In an analysis of the foregoing cases, the following points seem to me of practical importance.

In Case 2 there was compression of the cord with paraplegia, due to the presence of a tuberculous neoplasm. This paraplegia had persisted from May 28, 1889, to Dec. 3, 1889, a little over six months. The tumor was removed and the functions of the cord were restored. While the character of the compression was sufficient to interfere with the conductive power of motion and sensation, these functions being completely suspended for six months, the ascending and descending degeneration of the cord evidently took place in so slight a degree that the conductivity of the cord was restored after the removal of the compression.

In Cases 3 and 4 there were no external evidences of fracture, and while I am convinced that extra-dural hemorrhage occurred in both of these cases, due to otherwise insignificant injury of the bodies of the vertebrae, thus rupturing some of the veins which pass out of these masses of bone, I am sure that no compression occurred from displaced bone. There was no projection or depression of the spines in either one of these cases, a condition which in all the other cases of fracture pointed very directly to the seat of injury. The appearance of the spinal cord in these two cases was unlike that in any of the others; it was very much reduced in size at the point at which the incision of the dura was made and seemed paler

and more anemic than the others. The paraplegia and the ultimate fatal result in both was due either to pachymeningitis, which was the result of the traumatism, or to general concussion and myelitis which followed in the cord and which condition resulted in degeneration of this organ. That the paraplegia was due to the extra-dural hemorrhage and was local in character, I think is evident from the fact that the line of paralysis did not change in these cases from the day of injury to the day of death; in other words, there was no general atrophy of the cord above the seat of injury.

It will be observed that both of these cases were injured by falling directly upon the back, one falling upon the floor and injuring the head at the same time; the other falling upon the ground, striking upon the back.

In Case 1 the patient was struck on the head and the fracture took place at the dorso-lumbar junction as the man was doubled forward upon himself.

Case 8 was injured while diving, striking upon his head and producing a crushing of the upper two dorsal vertebrae.

Case 9 fell from a height, striking on his sacrum and buttocks, fracture occurring at the cervico-dorsal junction.

Case 11 struck upon the back of the head, fracturing the fifth cervical, no doubt crushing the body and fracturing both laminae at their junction with the body.

Cases 5 and 6 were in all probability lesions caused by *contre-coup*, but upon this point I could not obtain a positive history.

Only two cases were due to *direct* violence; one of these, the remarkable case of gunshot wound of the cord; the other due to the impact of a heavy stone upon the spinous processes of the injured region.

As to the results of the cases given, three were not operated upon. One of these was greatly improved by extension and counter-extension, the fracture occurring in the dorso-lumbar region where this plan of treatment can be satisfactorily carried out. The same treatment was undertaken in the other two cases, but with no improvement in their condition. Both are living but their conditions are decidedly hopeless.

Of the eight cases upon which I operated, one was entirely cured (case of tuberculous tumor); another, the young man who was injured by being thrown in front of a locomotive, although the operation was done eight months after the injury, was in my opinion greatly benefited thereby, and is still living and able to get about with a cane and crutch. The other cases were in no way benefited by operation.

Of these eight operative cases, one died six days after operation, and his death may have been hastened somewhat by the interference, although it is clear that destruction of the spinal cord at the level of the fifth cervical vertebra could not long have been survived without interference, by reason of extension of the ascending degeneration to the branches of the phrenic nerve.

In none of the other cases could a fatal result be charged in any way to the operation. Indeed, in my opinion, when properly performed, the operation involves so slight a risk to life that it should encourage the surgeon to advise this method of exploration in all cases in which the symptoms point to compression of the cord. I would be deterred from advising opera-

¹ Day of operation.

tion in any case by nothing except the great depression of pulse, respiration or temperature which is occasionally met with. In one of my cases, the temperature was down as low as 91 and did not go above 96 in twenty-four hours.

The method of operating I employed in each case is as follows: With the patient in the prone position, reclining somewhat upon one side in order to interfere as little as possible with the movements of respiration, an incision, the center of which is the seat of lesion, seven or eight inches in length is made directly over the spines. Retraction should be made by strong hooks, which controls hemorrhage in good measure; the attachments of the muscles should be cut or scraped from the bones in order to avoid wounding any vessels. In this way the laminae are finally exposed and with a small rongeur are divided and removed one after another until the dura is sufficiently exposed. If there is considerable oozing, this should be stopped by packing with sterile gauze, taking care not to make pressure on the exposed dura. After the wound is entirely dry, the dura is opened by a sharp-pointed knife, cutting down carefully in the middle line until there is an escape of a drop or more of clear cerebro-spinal fluid. Through this primary puncture a dull-pointed grooved director should be inserted, and the dura divided exactly in the middle line as far as necessary. When the fluid escapes the edges of the dura can be held apart by mouse-tooth forceps and the cord inspected. If the latter is touched with the finger it should be very lightly and carefully done; a light, dull-pointed probe should be passed up and down from the point of opening to determine whether or not the compression of the cord exists above or below. In one instance, following this precaution, I found that as the probe was arrested by the projecting bone, I was a inch below the real point of compression. The dura should then be closed by fine interrupted catgut sutures about three-sixteenths of an inch apart and the muscles of the two sides stitched together with strong catgut sutures. Silkworm gut sutures are used for the skin. It is always wise to leave a twist of catgut projecting from the level of the dura and out at the inferior angle of the wound, as some oozing is apt to occur which, if not allowed to escape, would exercise compression upon the cord. Most careful asepsis should be practiced. The patient should remain upon the back for the first week or ten days after the operation. I usually dress the wound about the fourth or fifth day. Patients seem to suffer no material inconvenience from removal of the laminae of two or three vertebrae.

ON THE EXPLORATION OF THE BRAIN WITH A NEEDLE AND SYRINGE THROUGH CAPILLARY HOLES DRILLED THROUGH THE SKULL.

Read in the Section on Surgery and Anatomy, at the Forty-seventh Annual Meeting of the American Medical Association at Atlanta, Georgia, May 5-8, 1896.

BY EDMOND SOUCHON, M.D.

PROFESSOR OF ANATOMY AND CLINICAL SURGERY, TULANE UNIVERSITY,
NEW ORLEANS, LA.

It is several years ago, in May, 1889, that I first drew the attention of the profession to the value and importance of exploring the brain with a needle through small apertures made in the skull. This

method was proposed to take the place of trephining, *i.e.* removing a ring or bone, before exploring the subdural spaces and the brain. The simplicity of the procedure and its safety recommended it as an easy means within the reach of a greater number than the other more serious and comparatively complicated operation of the trepan. By its ready employment it was expected that many lesions, specially abscesses, cysts and hard tumors, could be earlier diagnosed and located with certainty after exploring by this means the region suspected from the distant symptoms.

To determine first the possible dangers from hemorrhage I conducted a number of experiments on dogs. The manner of proceeding was in thorough accord with the Listerian principles, and the spots for perforation selected with as much care as if an ordinary trepanation was to be performed. The instrument employed was an ordinary stem watchmaker's drill, to which I added an adjustable guard to prevent unlimited penetration of the drill into the brain substance after the penetration of the bones. An important factor the *size of the needle*; it should be at least twice as large as that of an ordinary hypodermic, lest the fluid, if thick, would not be sucked in by the syringe, thus leading to erroneous conclusions. Two dogs were thus treated, twice on each side, away from the middle meningeal artery. The needle penetrated two and one-half inches. After thorough recovery the same two animals were again subjected to the same process exactly. At no time did they show any signs of having thus had their brains explored repeatedly. One dog was killed while under the effects of the anesthetic and the parts exposed and examined thoroughly. All that could be seen was an ecchymotic spot no larger than a flattened pea under the pia mater, no more than could have happened if a crown of bone had been removed before using the exploring needle. Thus it was proved as far as these experiments went that it was possible and practical to explore the brain in several spots at the same sitting without being limited to the space and lines of a ring of trepan. It is only in cases of tumors of the same consistency as the brain, that is soft but not fluid, that the explorations would be of no avail and let matters remain in doubt, but this also would be the case if the trepan had been used instead of a drill. Even then, in some cases the microscopic examination of the particles expelled from the needle might give reliable information. May we not venture to predict that some day this process will be used to aspirate the extravasation of blood in the tissue of the brain or its ventricles in cases of cerebral hemorrhage, spontaneous or traumatic, as we do for a liquid hematoma of the soft parts.

It is also in the early detection of the mastoid and peri-audicular abscesses from middle and internal otitis that the method will afford most important results, whether positive or negative, the latter being then just as important and practical as the former.

Dr. R. Matas, who kindly assisted me in my experiments on the dogs, communicates the following case, which occurred in 1889.

"Patient had suffered for years with a chronic purulent discharge from the left ear and he suspected an abscess of the temporo-sphenoidal lobe compressing the inferior or middle pon-Rolandic region. He says he was so impressed with the simplicity and certainty of the capillary drill punctures that he decided to explore the patient's brain with the hope that if pus

was found, its subsequent evacuation by a large trephine opening might bring relief. It was done, at Barter's point of election for temporo-sphenoidal abscess one and one-half inch behind the center of the external auditory meatus and one and one-half inch above. Through the direct tract in the soft parts, the point of a spiral watchmaker's drill was introduced and a small hole was quickly made which involved the whole thickness of the skull almost through the vitreous plate. The resistance of the vitreous was easily appreciated so that due caution could be observed not to punch the whole drill with the point suddenly into the brain. The perforation of the skull was easily completed with the point of a No. 1 aspirator needle attached to an ordinary hypodermic syringe. The exploring needle (duly sterilized) was then introduced fully two inches into the brain and slowly withdrawn. Unfortunately no pus could be aspirated notwithstanding a perfect vacuum. Another drill hole, one inch in front of the last point and on the same line was made and the needle introduced with the same negative results. No effect upon the patient's condition was noticed when the needle penetrated the brain. Not the slightest variation in the pulse. Nothing to indicate that the two explorations had in any manner complicated the patient's condition. In view of these two negative results and the otherwise hopeless state of the patient we decided to desist from further explorative procedures. The patient succumbed in full coma the same night. No autopsy was performed, but I am satisfied from the failure of the carefully made punctures that there was no abscess and that the pressure symptoms and septic condition were accounted for by meningeal exudation and septic sinus phlebitis."

My growing interest in this subject induced me to undertake extensive bibliographic researches. In this I was most kindly assisted by Dr. W. W. Keen and by Dr. Hermann Gessner.

Apprehensions have been expressed as to the danger of hemorrhage. They are, a priori, not greater than when a crown has been removed and the needle run through the dura or pia mater. The fears are, however, more theoretical than practical, as demonstrated by the experiments related above and also by the experiments of Dr. Spitzka (Proceedings Amer. Neurological Assn., 1887). It has been thoroughly demonstrated that almost all the parts of the brain can be punctured with an exploring needle with impunity under thorough asepsis. This has been done time and again on the lower animals after using the trepan.

On the living human subject, Dr. Spitzka reports the case of a boy where, after trephining, the brain had been punctured in two places.

This case deserves more than passing notice, particularly because it is almost unique in the human subject and also in justice to the pains taken by the conscientious and thorough experimenter to follow it to its extreme limit.

The patient, a boy, aged 11, was thrown from a horse, and sometime afterward his symptoms became aggravated. Trephining at the point of injury was performed and a hypodermic needle introduced three times in various directions. No fluid was obtained. He died comatose three months after operation.

On searching for an indication of the punctures made none could be discovered on the surface of the brain nor in the pia, arachnoid and dura. On care-

fully making three sections of the region involved, three dark bluish lines were found extending vertically to the surface. One, the longest, measuring a centimeter in length, nearly reached the surface, and in the hardened specimen a slight pucker was found to mark the point which it would have reached if continued. The three showed the same composition, coagulated blood; at their deeper ends there was a rusty colored continuation, which microscopic examination showed to be due to the presence of a large number of blood corpuscles in the otherwise normal cerebral tissue. There was no spindle cell nor indication of any inflammatory disturbances whatever in the cortical or medullary tissues, nor did any of the nerve cells, as far as they could be identified, exhibit structural changes. The blood vessels were normal. I could discover no certain indications that any vessel had been wounded. Undoubtedly the three delicate tubular semi-clots represented the entire extent of the permanent damage inflicted by the probe punctures. So far as this case goes the harmlessness of exploring punctures is proven.

The conclusions drawn by the reading of Dr. Spitzka's paper is that practically hypodermic needles may be inserted with impunity, but he thinks that needles should never be introduced in the internal capsules, the contiguous ganglia or the lateral ventricles merely for exploratory purposes, unaided by positive clinical indications of the location of the disease. Surely no exploration should be attempted if no proper symptoms call for it.

In August, 1893, Meinhard Schmidt published in the *Archiv. für Klinische Chirurgie* an article entitled "On Perforations of the Cranium with Subsequent Diagnostic Puncture (explorations) of the Brain," and he mentions a case where this process was used; it gave a negative result, but this was most valuable in itself. The patient succumbed three days after the puncturing, to what proved a fissured fracture of the skull. The needle puncture site in the right temporal lobe, was marked by a fine patched star-shaped ecchymosis in the pia mater, scarcely the size of a lentil; the site of the puncture could not be found in the cortex, so that the direction itself could not be determined. Numerous incisions through the substance of the brain, made in various directions, gave no view of the puncture. There was neither any trace of the tract of the puncture nor any hemorrhage of whatever size to indicate its site. He considers it doubtful that any serious hemorrhage would take place even if a branch of the middle meningeal was traversed, as he thinks that upon the withdrawal of the needle the contraction of the coats will close the opening. The same applies to the middle cerebral. Of course, the tract of the longitudinal and transverse sinuses must be avoided unless they be inflamed, when they must be explored.

Maas, in 1869, mentioned the idea. (*Zur Casuistik und Therapie der Gehirnsabscesse nach eigenen Erfahrungen, Berliner Klinische Wochenschrift, 1869.*) He was at that time an assistant in the Breslau Clinic. However, nothing shows that he has applied it either on the lower animals or on man. He calls the process *Akidopeirastie*, meaning the proof by the needle.

Middeldorf, in 1856 (*Gunsburg's Zeitschrift für Klinische Medicin*), had anticipated Maas and seems to have used the drill on the mastoid process, on the frontal sinus, on encephalocele and encephalohema-

toma, but he does not mention the skull over the brain. He recommends a spoon-shaped drill point which cuts out the inner table of the skull and at the same time does not project through, so that it is less dangerous to the dura mater.

DISCUSSION.

DR. THOMAS H. MANLEY, of New York, said: The author referred to the question of the utility of his method of examining the brain by small punctures, but I question the propriety of using that or any other means of exploration in cases of hemorrhage into the brain substance or between the walls of the skull and the meninges. My experience in treating fractures of the skull has been large and I have some pretty pronounced views as a result of my own experience as to what I think is the safest way of dealing with hemorrhage. The teachings of modern surgery would imply that the rational method is to at once explore for the bleeding point and displace the clot, but I feel sure in those cases in which there is any depression of warmth, it is calculated to do more harm than good. Hemorrhage into the brain substance in certain situations is entirely beyond our reach, assuming that the clot could be safely dislodged. If there be an effusion of blood into the brain, there is no reason why that blood should not undergo rapid absorption the same as elsewhere, in fact more so on account of the high vascularity. It has been my misfortune in trephining and undertaking to displace large blood clots to open the vessels which nature had plugged with clots and my patients bled to death. Others may have had the same experience. A month ago I was called to see the wife of a physician who had slipped on the icy pavements and fallen, striking on the back of her head. She could not stand for a few moments, but after awhile she was able to make her way home. During the day she became conscious of a severe pain in her head, the sight became dimmed and somnolence developed. On the second day after the injury, I was called to see her, when she presented every evidence of fracture. She had complete paralysis of the muscles of the left eye, as well as the entire loss of vision. The right eye was also paralyzed, but the sight was unaffected. There was a slight elevation of temperature, about 100, but no paralysis. The case pointed pretty positively to a hemorrhage, probably into the posterior occipital lobe of the cerebrum, and the question arose what was the best to be done. There was no hemorrhage from the ears or nostrils, but she was developing meningitis. The only thing that pointed to fracture was large ecchymosis into the conjunctivæ and both eyes were distended. A consultation was held with one of the most distinguished neurologists in New York and also with a surgeon who was a relative of the patient, and it being decided that there was a hemorrhage, trephining was suggested. I took a bold stand against that procedure, and I felt so certain my course was right that I said I must withdraw from the case if the trephining was performed, because I believed it would kill the woman. The husband supported me, the skull was not trephined and the woman made a good recovery. As far as hemorrhages into the brain are concerned, I wish others would give us their views. Is it their opinion that we should or should not trephine for hemorrhage? This might be well in suppurated disease of the mastoid and purulent processes stretching along the anterior lateral walls. It strikes me if we undertake to employ this or any other means we should be ready at the same time to go on and do the operation, and the anesthetizing of the patient should be just as complete as for any other operation.

DR. NICHOLAS SLENN of Chicago, said: The paper is a very valuable one and is calculated to add dignity to the Session. I somewhat disagree with the author but some of the ideas he has advanced will lead to very valuable results. From a practical standpoint, I must confess that I have more often been

disappointed than anything else in using the needle. I have never gotten any diagnostic information equal to inspecting and palpating the surface of the brain because diagnostic palpation can be relied upon. If the needle yield a negative result, you will very largely draw an erroneous conclusion. We can not estimate the extent of its diagnostic resources by the size of the cranial cavity, and I think that a small perforation is attended by more danger than by opening the skull; in fact, it is the experience of every surgeon that it is the small wounds that are so prone to trouble us, for obvious reasons. I combine puncture of the brain with a temporary resection of the skull at the point I believe to be the seat of the disease and this temporary resection yields very valuable diagnostic information. In the first place, after having laid the brain free, one can form some idea whether it is necessary to puncture or not. If I am still uncertain, I follow with palpation. These methods will show the presence or absence of an intra-cranial tension. If there is no tension there is no need of a needle puncture, but if there is tension, the needle should be used. It is here where the needle so often yields erroneous information. When I puncture the brain, I always combine with it the modern aspiration. By puncturing the brain carefully in the direction where we have reason to believe an abscess exists, the sensation imparted to the finger is of great value in determining between a solid tumor and a cyst. Increased resistance of the needle will help you. The needle can only give positive results in the case of fluids, pathologic productions such as blood, serum, cysts or abscesses. Again, the needle can not be relied upon as an absolute diagnostic test even in the presence of an abscess or a cyst, but the surgeon may utilize it as a guide to reaching the abscess. I feel therefore that I must look upon the needle only as a diagnostic resource, as an aid in making diagnostic tests. One day after making a temporary resection of the skull, finding no possible indication of an intra-cranial lesion and wishing to explore the brain in different directions in a systematic manner, I made a puncture and was horrified by a sudden movement of the head of the patient. I knew that this sudden movement had resulted in extensive damage to the brain, and I do not wish to repeat a similar experience. You are all aware of the fact that an ordinary exploratory incision can not be relied upon. Another thing, the needle is difficult to sterilize and frequently the apparatus will not work at the proper moment. I wish to substitute for the needle the method of suction by using a bulb that I can empty. This I connect to a rubber tube and attach the trocar, which is movable to the canula and the exhaustive apparatus. The vacuum can always be relied upon in making the suction and I have been very much pleased with this method.

DR. ALEX. HUGH FERGUSON of Chicago said Dr. Souchon's paper is a good one, but from my own experience, I think it is very unreliable and I would not care to rely upon the needle. The same is true of drainage. I remember a case of abscess which had a typical history of middle ear disease, etc., and on exploring with the needle, I could find no abscess but the surface of the brain manifested the signs of inflammation. In certain cases the needle may be very useful, but sometimes the coagulation of the blood is very rapid so that it would not be as serviceable as one might expect. If there is an injury of the brain substance and a good deal of hemorrhage we substitute something else, as for example gauze packing.

DR. SOUCHON, in closing the discussion, said: I intend this needle to be used merely as a preliminary step to be followed immediately by one of the proper methods of treatment. As regards the exploration that has to be done, there are several reasons why the needle is useful. The size of the needle is a very important matter. Sometimes the method will fail upon the first trial because the apparatus does not work properly, or the needle may be rusty or too small. I have seen my assistant exploring with a needle that was too small and no good resulted. I can not emphasize other good points at this time.

EXPLORATION AND TREATMENT OF FISSURES FROM SKULL FRACTURES.

Read in the Section on Surgery and Anatomy at the Forty seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY H. H. A. BEACH, M.D.

BOSTON, MASS.

The modern treatment of fractures of the skull, which includes the uncovering of all suspicious areas suggesting depression or the projection of bony spicule toward the dura, the removal of fragments and foreign matter of every description, the arrest of hemorrhage, adequate provision for drainage, faithful observance of asepsis both in operating and dressing, with such attention to the general condition of a patient as may be requisite, is, in a word, the impression that Lister and his teaching have made upon the surgical work of pre-antiseptic days.

The results obtained before that time through the faithful and painstaking application of surgical principles, of which cleanliness as then understood was the corner-stone, are scarcely less astonishing than those of to-day, if just consideration is given the work prosecuted in ignorance of the existence of bacteria and their appalling ravages.

The confidence and boldness with which the surgeon may now undertake explorations involving the gravest consequences, have really been the outcome of protection afforded from the toxic effects of septic disease by the gradual development of aseptic principles. Wonderful advances in saving lives and the brilliant results of daring operating have made the field of cerebral surgery a most attractive one during the past decade. With all the advantages, however, afforded by aseptic precautions, the mortality of skull fractures involving the base remains high. This mortality has an association with such elevation of temperature as to point unmistakably in the direction of septic infection as an explanation, and leads to the doubt of a perfect asepsis in all cases. Without question a certain share of the mortality is inevitable from severity of injury as well as from incidental complications that are independent of sepsis. Crushing injuries of the head with extensive laceration and destruction of tissue, together with abundant hemorrhage, will surely determine a proportion of more or less early and irremediably fatal results.

Of the patients who survive the immediate effects of injury, a number are subject to a comparatively slight rise of temperature for a short time, associated with varying symptoms of concussion, and ultimately recover. The remainder improve for an uncertain period from several days to a week or more, then gradually develop a temperature that, with occasional and irregular fluctuation, rises as the patient gradually sinks to his death. It is possible that of this last group some die from chronic inflammation of brain tissues following their contusion or laceration and the interference with its nutrition through the pressure effects of masses of clot, added to the degenerative changes characteristic of those processes. Progressively high temperatures common to fatal cases, however (though every care prescribed by aseptic rules be followed), and their similarity in other respects to those treated without aseptic precautions make it doubtful, to say the least, if sepsis has been completely eliminated from them.

The reduction of this mortality is a problem that now confronts the surgeon, and as an entering wedge

toward its solution, the importance of a series of observations that will establish beyond doubt the relation of sepsis to the fatal results can not be overestimated. Much may be accomplished by the systematic and accurate observation of all cases of fractured skull where there is any open surface requiring dressing or where any discharge exists, by making bacteriologic cultures, at intervals during life and at the autopsy; briefly, freedom from sepsis should be definitely and unmistakably proved in any fatal case by the unassailable evidence supplied by carefully made bacteriologic tests, to clear it from the suspicion of putrefactive infection. With the belief that such inspections will show cases heretofore unsuspected to be septic, and therefore requiring a more rigid application of aseptic principles, I venture to add that a logical deduction from the same combination of symptoms with wounds in other parts of the body would direct the attention of the surgeon to the vital importance of finding, if possible, the source of infection and applying the proper remedy.

In making this search, one is impressed with the invariable freedom with which the immediate seat of injury is now inspected, cleaned and dressed, relieving in a measure the region of direct violence from the suspicion of contamination.

In considering the more remote sources, the common association of bloody or serous discharges from the ear or nasal passages, continuing for days after the injury, and in some fatal cases to the end, suggests possibilities of bacterial infection through the extension of a fracture by fissures to the internal ear where an old otorrhea can supply the material in abundance for polluting the discharge from the interior of the skull; or, by the destruction of the membrana tympani, establish direct connection on one side with the air through the external auditory meatus and by the Eustachian tube to the cavity of the naso-pharynx, which Paul Raugé terms "the storehouse from which the infective elements passing through the tube into the tympanum are derived." Fissures communicating directly with the nasal cavity are of necessity open to the same infective influences.

A large percentage of those who die from skull fractures have these bloody or serous discharges, also those who survive for more than five or six days and then die. On the other hand, a good proportion of those who recover have the same history; from which it is proper to infer that such discharges are not in themselves necessarily fatal, nor the bony fissure associated with them. Another explanation for fatal cases must be found either in the character of the injury to the brain and its vessels, or that of the fissures through which the discharges escape. Admitting that cases of severe contusion or laceration may die in a few days, or less, with elevated temperatures but without septic infection, until time and observation shall prove that question beyond doubt, we have left as an active factor in the results, the differences in fissures produced by their location, the parts toward which they trend, and the mobility of the bones which they separate.

A fissure through bones fractured with so much force as to leave them loosely connected would be more likely to supply an avenue for infective material to reach the skull cavity than one that could be barely detected and closely resembled a crack in glass or porcelain. The variations between these extremes are common to all fractures and may explain a part,

at least, of the differences of results in cases presenting similar symptoms. Though the flow of blood or serum may be nearly alike in a given number of cases, the quantity is not a safe guide to the extent of bone separation.

I need not dwell upon the difficulty of making the middle ear as aseptic as it should be, to warrant a communicating opening with the brain free from danger. The cavity of the skull stands with that of the peritoneum, in the importance of maintaining perfect aseptic defenses. The most dangerous of the combinations described, a loose fracture extending into a suppurative ear, of long duration, with fresh bloody or serous discharges, suggests a way for attacking less serious cases, by approaching the septic area from the region of the direct injury. By the use of the rongeur, a fissure extending in the direction of the ear can be widened into a channel of half an inch, to the base, through which the brain or dura may be lifted with a blunt retractor and the extent of the fissuring determined. The auricle may then be dissected forward so that a fissure can be followed to the mastoid and into the auditory canal, permitting the protection of its inferior aspect, for a distance, by gauze. Having inserted a protection of gauze between the upper aspect of the fissure and the dura or base of the brain through the channel made by widening the fissure, the latter also may be packed with gauze connecting it with the gauze at the vertex, limiting hemorrhage and providing an excellent drainage apparatus from the vertex to the base of the skull without causing undue brain pressure. With a previous history of a suppurative ear the tympanum should be freshly disinfected after carefully protecting the injured parts. The auricle is then rolled forward and the region included in the aseptic dressing.

As the possibilities of infection can not be estimated before unfavorable symptoms develop, and as it is then too late to institute aseptic measures, however radical, a conservative treatment would naturally include, at the first inspection of the wound, a most rigid asepsis, the following out of fissures with the utmost precision, uncovering the whole circumference of the skull opening for that purpose, and providing unlimited drainage by widening the fissures into loosely connected bone, that extend in the direction of the base.

When nearly 50 per cent of brain abscesses originate in suppurative ear diseases, the isolation of this region from the brain and its attachments during the repair of a fractured skull becomes a serious question; whether, in view of a steadily increasing temperature in spite of our precautions, and in the absence of other causes, it may not be justifiable to make a more radical clearing and asepsis of the ear cavities than can be obtained without anesthesia. The danger associated with such a procedure through the possibility of forcing, by washing under pressure, septic material from the tympanum through the fissure to the interior of the skull, emphasizes the importance of an adequate *primary* asepsis of the ears in fractures connected with them.

Death may follow ear suppuration by injury from below as I have observed in a hospital case some years ago, where an attempt was made to commit suicide by firing a revolver, ball caliber 38, into the neck at a point in front of the sterno-cleido-mastoid muscle and on a level with the angle of the lower jaw. The

wound of entrance passed directly upward between that bone and the mastoid process and perforated the meatus, where the ball was tightly wedged and could be felt from the outside with a probe passed by the ear, as well as through the wound from below. Ready access to the ball was obtained by dissecting the auricle forward. After its removal suppurative middle ear disease followed and the patient died from a large cerebral abscess of the right hemisphere immediately above the infected area as shown by autopsy.

In conclusion I will add one case only as an instance of what the complete exploration and widening of fissures may accomplish in the prevention of infection through its abundant provision for drainage and asepsis.

A well-developed man, M. S., age 36, entered the Massachusetts General Hospital with the history of having been struck on the head with a large piece of coal that had fallen thirty feet. He was conscious, rational and without paralysis. The pupils were equal and reacted to light. Pulse 100 of fair strength. There was bleeding from the right ear and at the parieto-occipital angle a scalp wound two inches long connecting with a depressed fracture. The head was shaved and made aseptic.

Upon uncovering the fracture a circular depression of two inches diameter was found with shelving edges. After removing a few projecting points with the chisel, the fractured bone was elevated and the dura exposed. It was darkened from contusion but not torn. Pulsation was slight when the fragments were removed, and hemorrhage free.

Upon inspection of the opening into the skull a fissure was found on the right border extending in the direction of the right ear. The scalp was then dissected up in the direction of the fissure until the external auditory canal was reached. As the auricle obstructed a complete exploration, the incision was continued in the direction of the mastoid and the bony canal exposed by dislocating the auricle forward, showing an extension of the fissure anterior to the mastoid into the canal. The separation of the fractured bones was complete, permitting their easy displacement, to and from the brain, but not laterally from the line of fracture so as to permit a satisfactory examination.

It was clear that the hemorrhage from this fissure unless arrested promised everything in the way of sepsis. To close it and at the same time supply necessary drainage for the cavity above, it became necessary to widen the fissure to the width of the rongeur (one-half of an inch), from the opening at the vertex to the level of the base. Then it was easy to lift the dura from the region of the fissure and after washing out the cavity to pack it with iodoform gauze as before described. A few silkworm gut sutures through the skin and across the channel helped to keep the gauze from becoming displaced, and over all the usual aseptic dressing was applied, including the external ear.

His temperature reached 101 degrees for one night (the third after the operation), then remained between 100 degrees and normal during the succeeding two weeks. The pulse ranged between 60 and 75. He had a slight headache on the first day after the injury. The gauze drains were gradually removed; upon the thirteenth day the wound was granulating well and he was up and about the ward. There was deafness of the right ear and some facial paralysis of that side.

He was discharged well in two weeks, previous to which his ear was examined by Dr. J. Orne Green, who found that the fracture had involved the labyrinth with the facial and auditory nerves, and made the prognosis of permanent deafness.

DISCUSSION.

The Secretary, Dr. W. L. ESTES, said: It seems to me that the questions involved in this paper should not pass unnoticed, as they confront every surgeon and may occur to every practitioner. Dr. Beach has brought out with great clearness the necessity of disinfection, the production of a septic state and the employment of proper drainage. These are the principles on which every surgeon works. Fractures at the base of the cranium are those which are perhaps least practicable in obtaining thorough asepsis and drainage. It seems to me that physicians do not recognize the necessity of proper disinfection of the avenues of asepsis, i. e., the nares and the external ear. It has been my fortune to have to treat cases which had been seen previously by the family physician who was not accustomed to work in aseptic surgery, and I have found that there has been absolutely no attempt at disinfection of the nasal passages or the external auditory meatus when all the symptoms have led to a fracture involving the base. It seems of the greatest importance that this Section should advocate and impress upon practitioners the absolute importance of disinfection when there is no question about the external cavities being involved. It is my custom to thoroughly douche or spray the nasal cavities, and to plug them anteriorly and posteriorly, if necessary, with some disinfectant gauze. After thorough disinfection of the external auditory canal I plug it also. Now as to drainage, it is sometimes a serious matter to do this in fractures of the lowest basilar indication. If it involves the area which is posterior to the auditory canal, it may be an easy matter, but if it involves the anterior area, it is more difficult. There is no question that the propositions of Dr. Beach are the proper ones. No matter what the danger may be, the greatest danger is in neglecting the matter. It seems of the greatest importance to widen the fissures, if necessary, and to be sure that adequate drainage is provided. The question of hemorrhage is a most dangerous one. The sinuses need not necessarily be injured, but the meningeal vessels would probably be those especially involved. Great care and blunt lifting of the dura will usually permit the securing of proper drainage.

CEREBRAL SURGERY; REPORT OF CASES.

Read in the Section on Surgery and Anatomy, at the Forty seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY J. C. OLIVER, M.D.

CINCINNATI, OHIO.

As this paper is one dealing with the general subject before this Section, I shall simply report cases, knowing that the points in regard to cerebral surgery as a whole will be taken up and discussed by men far abler and more competent than myself.

Case 1.—This case is presented, solely for the purpose of illustrating the very great difficulty which occasionally surrounds our attempt at cerebral localization in traumatic cases.

Robert C., aged 59, finely developed and nourished, February 22, 1896, fell about thirty feet through a dust chute in a cotton factory. Probably remained lying at the bottom of the chute for about one hour before being discovered. I saw him at 8:30 p.m., Feb. 22, 1896, in consultation with Drs. A. R. Walker, W. H. DeWitt and P. W. Good. This was about four hours after the accident.

Examination showed an extensive bruise of the scalp in the median line of the vertex, extending slightly farther to the left than to the right side. No fracture of the skull apparent. There was ptosis on the left side, hemorrhage from the left nostril, motor aphasia, both pupils were midway between contraction and dilatation and did not react. Patient was rest-

less, would arise from the bed and could stand upon his feet. Both arms and legs were used freely. He could understand what was said to him and made efforts to respond but was unsuccessful. No vomiting. Examination of chest revealed fractures of second and third ribs about the angles. The symptoms otherwise were negative.

Diagnosis: Fracture of base of cranium and fractured ribs. A very guarded prognosis was given. An ice-cap was ordered for the head and K. br. given every three hours in scruple doses.

February 23, patient seems some brighter; restlessness much less; sleeps soundly, snores considerably. Ptosis seems somewhat less. Other symptoms about the same. Continued treatment. Slight fever developed to-day. The future history of the case is one of increasing fever and gradually deepening coma. I did not see the case again until after death, he, in the meantime, being under the care of Dr. A. R. Walker. He died at 9:30 A.M., Feb. 26, 1896. Temperature just before death, 105.

Autopsy was made by Dr. Frank Fee, six hours after death. P.M. rigidity well marked. P.M. staining slight. Prominence corresponding to bruised area on vertex, depression anterior and posterior to it. Bruising over left side of chest.

Head: Large effusion of blood in the scalp at the vertex. No fracture. Brain had small bloody effusion in the most posterior and lowest part of the occipital lobes on each side, most marked on the right. Otherwise brain normal.

Meninges: Smoky from beginning inflammation. No pus. Middle meningeal artery of left side ruptured, about a dram of blood effused.

Base of skull: Two distinct fractures, one of left orbital plate and one of left cribriform plate. Fracture not extensive. Skull very thin.

Chest: Second and third ribs fractured posteriorly, fourth, fifth, sixth and seventh fractured near junction with costal cartilages. Heart and lungs normal.

Abdomen: All organs normal except kidneys and liver; these were fatty and the left kidney presented three cysts.

Cause of death: Fracturae basis cranii.

Case 2.—Dr. H. H. Hoppe, Neurologist to the Cincinnati Hospital, had this man in his service. In order to save time I will abridge the medical history and confine myself to the essential points. These were Jacksonian epilepsy, the convulsion always beginning in the left leg, then involving the left arm, then the left side of the face and then becoming general. These convulsions occurred in groups, so that he would have ten to twenty in a day (status epilepticus). Following the convulsion the patient would have a left sided paresis, which would only remain for a few hours. After passing through these attacks, the patient would become maniacal, in which condition he was dangerous to those about him. These were in brief the only points bearing upon diagnosis.

From the above symptoms Dr. Hoppe concluded that some irritation existed in the leg center on the right side of the brain, and turned the case over to me for operation.

On August 31, 1894, after the usual preparation of the patient and site of operation, he was taken to the amphitheater for operation. Chloroform was the anesthetic used. A crescentic incision was made over the right parietal region, the bone having been previously "scored" with an awl to mark the course and location of the Rolandic area. After the flap had been turned back and the hemorrhage controlled, an inch trephine was applied and a button of bone removed over the area corresponding to the leg center. Before using the trephine, there was noted a blue line in the bone running downward and forward, almost parallel to and about one-half inch behind the Rolandic fissure. The opening in the skull was enlarged by means of a rongeur forceps, downward and forward. In the process of enlarging the opening, there was opened a large vein running in the diploe. This vein was what caused the bluish line above noted. It had eroded the inner table of the skull and had caused an absorption of the dura immediately under it, so that there protruded through the dura, a hernia of the pia and brain. I should state, lest the above description be misleading, that there was a varicosity in the vein

about the size of a pea, and that it was at this point that absorption of the outer and inner tables and dura had taken place. The line of the vein was followed with the rongeur forceps, the dura was opened by a crucial incision and both it and the pia were found much thickened and edematous. The convolutions of the brain appeared normal, consequently no further exploration was made.

To arrest the hemorrhage from the vein in the diploe, it was found necessary to close the channel with a piece of sterilized match, this being left *in situ*. The incisions in the dura were sutured with interrupted catgut sutures, the flap from the scalp being closed with a continuous silk suture. The head was enveloped in an aseptic dressing, held in place by a crinoline bandage.

At 7 P.M. on the day of operation, the patient was in good condition, the pulse was good and he was comfortable. The dressing had to be changed because of the blood soaking through it. On September 1, the dressings were reapplied. There was but little external hemorrhage, but a considerable hematoma had formed under the scalp. The edges of the wound were slightly separated with a pair of artery forceps and the blood allowed to escape. Temperature normal. September 6, stitches removed; no suppuration. Examination of special senses negative. For the first two days after operation the patient was restless, irritable, exacting and surly. Since then he has been much more amiable. On September 19, a note says there have been no bad symptoms and he pronounces himself well. September 26, patient complained of pain in the left leg, chiefly in the region of the knee; is unable to explain the same. Examination negative. Says he has had no symptoms such as he formerly had when a convulsion was impending. October 1, he is up and around the ward. Says he feels perfectly well.

Following the operation, the patient experienced a complete cessation of convulsions for a period of six months; after this he began to experience pain in his left leg and there was a gradual return of the convulsions. He re-entered the Cincinnati Hospital June 4, 1895, and I again saw the case with Dr. Hoppe. We believed the return of the convulsions was dependent upon the fact that adhesion of the membranes to the brain had taken place and the irritation came from this condition.

With a view to remedying the condition I again operated upon him. Very dense adhesions were found over the area of the former operation. These were very carefully separated and a plate of gold foil was placed between the surface of the brain and the cranial flap. The operation was a very bloody one.

Following the operation there was nothing of importance to note. The wound healed by primary union. The patient remained in the hospital until October 12, when he was transferred to the Infirmary. In a few days after his transfer I was informed that he had suddenly died during the night. None of the attendants knew the manner of his death but it is supposed he died in a convulsion.

By a piece of good fortune I obtained the opportunity to examine the head. The plate of gold was in position and had accomplished the purpose for which it was inserted. There was no gross lesion of the brain.

Whether the venous varicosity was the cause of the epilepsy or not, is an open question. Dr. P. S. Con-

ner, of Cincinnati, showed me a portion of the occipital bone which had been perforated by a varicose vein. In this case the patient had suffered from epilepsy during life and no other cause than the venous enlargement could be found post-mortem to account for the condition.

Case 3.—This was a private patient of Dr. Jos. Eichberg. The brilliant diagnosis was made by him and we are indebted to him for the medical history.

Wm. S., aged 19; family history negative. The patient had been working in a machine shop. No history of any injury for the last thirteen years. At that time there was a slight scalp wound (superficial) which has left a cicatrix about one-quarter of an inch in length, an inch to the left of the median line over the coronal suture; scalp around the cicatrix was not adherent. Has had no serious ailment until the present time. In June of the present year (1895), a swelling developed about the left eye.

Report of Dr. Jos. Eichberg: On the afternoon of the day of admission, I found, on entering my waiting room, the patient seated in a chair in an attitude of extreme dejection, the head lolling backward on the shoulders and the eyes partially closed, face extremely sallow like the color observed in pyemia or chronic sepsis, and expressive of pain.

When urged to get up, the patient walked into the examining room unaided, but with a slightly staggering gait. There was considerable hesitancy in the understanding of questions, but the answers were prompt, phonation was clear. There was great difficulty in any sustained effort at attention, so that the patient would have to be recalled from a sort of somnolent condition which seemed to supervene a few seconds after any intelligent effort. Patient stated that he had lost 27 pounds in ten weeks and that he suffered great pain over the entire head, pain being constant but accompanied by exacerbations of most intense suffering. The focus of greatest pain was always located on the left side toward the frontal region; from this point the pain radiated to other parts of the head. The bowels had been constipated, but this was possibly due to large doses of morphia necessitated by patient's insomnia, the pain in the head being worse at night. On testing vision it was found to be 20-70 in both eyes, but in the effort of looking at the card the patient would lapse again into stupor. According to the mother's statement, the somnolency had rapidly increased in the last forty-eight hours without any relief of the pain. There was found a paresis on the right side involving the face and both extremities; this existed without the knowledge of the patient or his friends, being too slight to attract attention, and affected the motor functions more than the sensory. Though the patient was a right-handed man, the muscular power of the right hand was manifestly less than the left. The pupils of both eyes were dilated and equal, dilatation existing in spite of the giving of morphia in large doses. Pupils reacted promptly to strong light, becoming dilated almost immediately after the stimulus was withdrawn. The tongue protruded in the median line. With the ophthalmoscope a very characteristic choked disc was found in the left eye. Veins exceedingly tortuous and enlarged; convexity of papilla very evident. The deep reflexes were normal. Slight scar noticed below the supraorbital ridge, where, according to patient's statement, a swelling had been incised two weeks after the onset of his illness. Temperature 98 in the mouth. Pulse 84, irregular and rather hard. Breathing 22, also irregular in rhythm. Lungs normal; heart normal; spleen slightly enlarged; face emaciated.

Diagnosis: Cerebral abscess of left frontal lobe,

producing paresis of right side from indirect pressure against internal capsule.

Dr. Eichberg asked me to see the case with him on the evening of Sept. 11, 1895, and to come prepared to operate for cerebral abscess. We saw the patient together at about 9 P.M. A young man of good physique sat in a chair apparently oblivious to all that was going on around him. The other symptoms indicating an operation have been so well described that I shall not repeat what has already been said. This stupid condition was so marked that I asked his father whether the boy had ever been bright or intelligent. He assured me that the boy was naturally bright and was a competent machinist. Arrangements were immediately made for opening the skull. At the consultation with Drs. Eichberg and Kebler, the question of localization had been thoroughly discussed and we agreed that the trephine opening should be made over the left frontal region, as we believed the abscess to be located in that part of the brain, and that the parietic symptoms were due to indirect pressure. A point of interest, and possibly of importance, was that the scar from an old injury (inflicted thirteen years previously) was plainly visible over the left frontal region.

After the scalp had been shaved and sterilized, a horse-shoe shaped incision was made and the tissues rapidly retracted from the bone, an inch and a half trephine was then applied and the button of bone removed. The dura mater bulged strongly into the opening and showed no pulsation; the dura was now opened by crescentic incision and detached from the convolutions. A grooved director was passed into the brain substance in several directions; finally a slight resistance was encountered about one inch below the surface, and when this was overcome by pressure upon the director, pus flowed along the groove. A pair of hemostatic forceps was now passed along the director and the blades spread apart; this permitted a free discharge of the pus. After the pus ceased flowing, I passed my little finger into the cavity and by so doing discovered a second abscess, which was opened by pushing a finger through its limiting membrane. Although the quantity of pus was not measured, I am inclined to believe that I am not overstepping the limits of truth when the quantity is given as three ounces. A large drainage tube was carried into the cavity and gauze packed around it, the ends of the gauze being brought out of the lower angles of the wound. The flap was perforated and the drainage tube brought out of the opening. The edges of the incision were now brought together except at the lowest point, where the gauze was brought out. The usual aseptic dressings were applied and the patient put to bed in very good condition.

After History: Patient recovered very nicely from the anesthetic. When he became conscious, there seemed to be some improvement in his mental condition. Some convergence of the eyes still present, right pupil slightly more dilated than the left. Sept. 12, 1895, the wound was redressed this morning. Considerable pus was present under the flaps; to facilitate the removal of this, a couple of stitches were taken out. The mental condition and paresis are improved. September 13, some convergence of eyes still present. Pupils are equal and react to light and accommodation. Vision for near objects good, but diplopia exists when distant objects are looked at. A considerable edema of the side of the head and face

was present this morning. A few more stitches were removed and the flaps separated by a pair of forceps; this manipulation permitted quite an amount of pus to escape. On the following day, September 14, a fungus cerebri began to present. The drainage tube, which had never been at all satisfactory because of the stopping up of its lumen, was now entirely discarded and gauze drainage alone was used. The patient from this time on showed a steady improvement. The fungus cerebri was allowed to take care of itself, which it did in a most satisfactory manner, finally disappearing about four weeks after the operation. The temperature at no time subsequent to the operation reached 100, and the convalescence was uninterrupted, unless the fungus cerebri could be called an interruption.

One curious feature of the case was the behavior of the pulse during the operation. When fully under the influence of the anesthetic (chloroform), the pulse was about 160 per minute; when the abscess was punctured, the number of beats suddenly fell to about 60 per minute and remained so. At the present time the patient is in perfect condition. He has resumed his occupation, that of a machinist. There are no symptoms of the trouble present. His mind is as good as it ever was.

Case 4.—Mr. C. S. B., aged 26; printer; white, well developed and nourished. Father living and healthy, mother healthy. Had jaundice ten years ago. Had the usual diseases of childhood. Had peritonitis two years ago. Otherwise has been healthy.

The early history of this attack as furnished by Dr. E. E. Sattler is as follows: In July the patient first came to my office with an intense, acute otitis media, drum bulging, fluid in the middle ear, intense suffering. A paracentesis of the drum membrane was made and fluid of a mucous character was evacuated. The fluid at that time was more mucous than purulent and has continued so ever since. About ten days later, the pain increasing and the discharge showing signs of diminishing, the drum membrane in the most prominent part was punctured with relief to the symptoms. The puncture was followed by profuse discharge. Since that time the ear has discharged freely and the patient made daily visits to the office until last Saturday, Oct. 12, 1895. During all this time he has been following his usual avocation, that of a postal clerk.

On Sunday afternoon, October 13, Dr. Sattler was called to see the patient at his residence and found him comatose, pulse about 90, pupils contracted, size of a pin head, slightly reacting to light, Cheyne-Stokes respiration. It was immediately recognized that some serious implication of the brain was present, most probably secondary to the middle ear trouble. A hypodermic of pilocarpin muriate was given, which was followed by profuse diaphoresis. He seemed some better that night, partially came out of the comatose state, made incoherent remarks and at times even recognized his relatives for a moment or so. On Monday he was rational, off and on, but soon sunk into a semi-comatose state from which, however, he could be rallied. Pulse weak and fast, 120. His removal to the hospital was advised in order to have an operation performed upon him. The mastoid has never been involved, but he has had severe headaches occasionally.

The notes of the case taken at the Cincinnati Hospital are as follows: Earache three months and a half ago, for which he consulted an aurist, under whose care he has been ever since. The notes regarding that period are those given above. The present attack began with a severe pain under the left frontal eminence. The patient was depressed and intellect clouded. Stupor increased, he became restless at

times. Yesterday morning the mental condition was worse but he could still answer some questions. Last night he was very restless, had high fever (103), and was delirious. This morning he was partially rational. Mother noticed increasing torpor to-day. He was unconscious upon admission at 5 p.m. Examination of the urine revealed a small quantity of albumin. Examination was as follows: Weight 145 pounds, height 6 feet 2 inches, right half of scalp shaved since arrival in hospital. Semi-comatose condition. Resists movements of head and eyelids; may be partly aroused by questioning, nods head in answer; unable to protrude tongue. Short intervals of consciousness during examination, followed by relapse into stupor.

Cranial Nerves.—First pair: No response to olfactory stimulation by ammonia. Third, fourth and sixth: Divergent strabismus; eyeballs deflected upward and outward; attempts to resist opening of lids by raising right hand; pupils small, equal; reaction to light sluggish. During short periods of consciousness eyes directed more forward but right eye still diverged. Individual ocular muscles can not be examined. Fifth: No response to tactile stimulation; shows appreciation of pin prick over left cheek, left side of nose, right upper cheek and forehead; always uses right hand in attempting to protect himself from examination. Both masseters retract. Seventh: Face not notably drawn to one side; no evident facial palsy. Eighth: Pulse 132, regular, good tension, occasionally intermits; respiration regular, 26; no stertor. Ninth: Patient swallows well; no tremor of tongue. Eleventh: Trapezii resists traction; unable to protrude tongue.

Motor Symptoms.—Upper extremities: Spontaneous movements: power markedly diminished; resists extension of both upper extremities; flexes them spontaneously. Lower extremities: Pigment cicatrix one inch in diameter over right tibia.

Sensation.—No patella reflex nor ankle clonus; some tendency to spasm of flexors of knee; no rigidity of flexors of ankles. Plantar reflex present. Abdominal reflex present and active; epigastric reflex present and active. No response to ordinary sensory stimulation of upper extremities. No response to pain or tactile stimulation of lower extremities below upper third of tibia.

Occasional drawing up of both corners of the mouth, as in trismus, was noticed. The patient was extremely restless, in almost constant motion during the examination.

A consultation was held at 5 p.m., Oct. 15, 1895, with Drs. Thorner, Langdon and Dandridge. From the symptoms presented an opinion was reached that we had to deal with either 1, an abscess located in the temporo-sphenoidal lobe or cerebellum; 2, diffuse purulent meningitis; or 3, a thrombosis of the lateral sinus. The unanimous opinion of the physicians was that it was impossible to distinguish between them and that an exploratory trephining ought to be done, first over the temporo-sphenoidal lobe, and if unsuccessful here, to open over the cerebellum on the right side. This being agreed to, the operation was set for 8 p.m. Drs. Dandridge, Thorner, Robert Sattler, Langdon, Fackler, MacMillan, Tate, Evans and the internes were present. After the usual preparations, the temporo-sphenoidal lobe was located at a point one and three-quarter inches above and one and one-quarter inches behind the center of the external auditory meatus. A half-inch trephine opening was made

here and then enlarged with rongeur forceps. When the dura was reached it was found to be tense but did not bulge. The pulsation of the brain was well marked both to the sense of sight and touch. A flap of the dura mater was then laid down and a grooved director passed into the brain in various directions. No pus nor resistance was found. An artery in the diploe caused considerable hemorrhage but was finally controlled by pressure. The scalp was now stitched in place and the wound closed without drainage. So soon as the former wound was closed, the skin and muscles of the back of the head and neck were laid back by a horseshoe shaped incision. A trephine opening (five-eighths of an inch) was made in the bone on a level slightly below the external occipital protuberance and slightly nearer the mastoid portion of the temporal bone than to the protuberance. The bone was tolerably thick. When the dura was reached it appeared normal, the pulsations were present and marked. After opening the dura, the cerebellum bulged into the wound somewhat. Exploration with a grooved director failed to locate any pus. The wound was sutured and the patient returned to his bed. He lived about forty-five minutes after his return to the ward.

A postmortem examination of the head showed diffuse purulent meningitis involving both the convexity and base. There was marked enlargement of the veins of the pia, and many of them showed dark clots in their lumen. The petrous portion of the temporal bone was carious for a distance of about three-quarters of an inch back from its apex on its superior surface. The upper edge of the carotid canal was partially destroyed and the infection seemed to have followed the line of the vessels, and did not, as is usual in these cases, pass through the roof of the tympanum at its thinnest portion, the tegmen. Examination of the parts showed that the trephine openings were properly located, and that had an abscess existed in either the right temporo-sphenoidal lobe or in the cerebellum, we could readily have evacuated it.

The important question in this case was that of differential diagnosis. It was readily apparent that some grave intracranial condition existed; it was also a fair interpretation of the symptoms to conclude that a meningitis was present, but it was impossible to affirm that the meningitis was *not* dependent upon a localized accumulation of pus which had produced a meningitis by extension of inflammation. The sudden onset, the rapid pulse, high fever (103), contracted pupils irresponsive to light, the restlessness, delirium, trismus, and the absence of localizing symptoms, all spoke in favor of a meningitis. We are all well aware, however, that an abscess may exist in the temporo-sphenoidal lobe or in the cerebellum, without distinct localizing symptoms. The man's condition was desperate, and would certainly have soon terminated fatally unless relief was afforded him. Such relief was impossible save through surgical intervention, hence it was our duty to afford him the chance offered by an operation.

While the termination of the case was an unfavorable one, it presented features of unusual interest. It emphasizes the fact that a differential diagnosis of cerebral abscess is a very difficult one. It also shows conclusively that the brain symptoms following middle ear trouble are not always dependent upon localized accumulations of pus within the brain. Another point of interest is that the mastoid cells escaped

infection. The route pursued by the caries explains why they were not infected.

Trephining for drainage and relief of pressure has been recommended in purulent meningitis, but the results are not brilliant. After some experience in pathologic work, I am convinced that there is another element at work in cases of meningitis besides the pressure and effusion to account for the almost invariably fatal result in these cases. The amount of exudation is ordinarily but small, and the resulting pressure should not be so great as to cause the symptoms and usual termination. The septic element should receive more recognition than is at present accorded it. As is well known, the conditions for absorption of septic matter are most favorable, and it seems reasonable to conclude that death is caused by the septic intoxication rather than by the pressure. If we grant the septic intoxication, we need not be surprised to learn that opening the skull and dura in these cases is not productive of amelioration of the symptoms.

DISCUSSION.

DR. RANSOHOFF, of Cincinnati—In the case reported it is said there was considerable hemorrhage, which is very frequent. Quite recently I have adopted a method by which hemorrhage from the scalp can be reduced to a minimum. Very often, owing to the loss of blood from the division of the dura, and from the cerebral veins after an operation for the removal of a brain tumor, the operation can not be completed at one sitting. Every drop of blood that is saved is of moment, and we all know that under the older methods much blood was lost. The use of the Esmarch strap about the scalp encircling the skull nearly upon a line with the base, is something that every one knows is applied with much difficulty. After much care, sometimes, the scalp sinks down into the orbit and the entire object of the use of the strap is lost, and the hemorrhage is profuse. I will call attention to a method of dividing the scalp without loss of blood, which method is a very simple one, although I have never seen a description of it. I practiced it recently in a case of sarcoma of the dura mater in which the tumor was as large as a small orange, after perforating the skull. It had been operated on twice before on the supposition that it was a wen. To prevent hemorrhage I introduced, about an inch from the surface of the tumor, a continuous chain suture, drawing it tight around the entire line of the incision. When it was drawn tight, which could be done rapidly, the entire area of the skull was made absolutely bloodless, and the incision was made within the line of the chain. When one considers the size of the incision that must be made for trephining, and difficulty of grasping the vessels in the tense scalp, one can readily appreciate how much blood will be saved the patient by using this suture. The first dressing must be changed in twenty-four hours for the removal of the gauze packing, and in that case the sutures can be clipped and removed. The use of this suture for twenty-four hours will not in any way interfere with the vitality of the flap.

The Roentgen Ray and "Second Sight."—Dr. Ottolenghi, of Naples, has suggested, in *Riforma Medica*, that the supposed power of seeing through opaque media, etc., which is claimed by certain hysteric somnambulistic or trance subjects, may have some objective basis in the light of the recent discoveries of Roentgen. The author supposes that in the more or less extra-normal conditions of the nervous system obtaining in this class of patient, the retina may be sensitive to the X-rays, which, under ordinary conditions, fail to produce any impression. This suggestion is only meant by the author to apply to such cases as are inexplicable in any other way.

OBSERVATIONS CONCERNING THE LAW OF PRIVILEGED COMMUNICATIONS BETWEEN PHYSICIAN AND PATIENT, AS APPLICABLE TO THE DUTIES OF RAILWAY SURGEONS.

Read at the Second Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Ill., Sept. 25-27, 1895.

BY HON. TRACY C. BECKER.

BUFFALO, N. Y.

Gentlemen of the Association.—I highly appreciate the honor conferred upon me by being invited to deliver an address at the meeting of the American Academy of Railway Surgeons on some topic connected with the medico-legal aspects of railway surgery; and upon reflection, have deemed it advisable to devote the time allotted to a consideration of the laws concerning "Privileged Communications between Physician and Patient," particularly as regards the application of these laws to the duties of railway surgeons.

As I understand the status of the members of your body, nearly every one of you is under contract of regular employment by some railway company, by which, in cases of accidental injury to its employes or its passengers, it becomes your duty to visit such cases and to give them the benefit of your professional knowledge and skill. If so, you are not, in the strict sense of the term, employed in your professional capacity by the party interested. It, therefore, becomes important for you to be informed as to how far any knowledge or information you may obtain while treating such patients can be disclosed without violation of your legal duties as prescribed by the statutes of the various States in which you perform those duties.

It is a singular and not commonly known fact, that under the English common law, while inviolable secrecy was required to be observed by attorneys with reference to communications which they received from their clients, no protection from disclosure in evidence in a court of justice was extended to communications between a medical man and his patient. The reason for this distinction has been said to be, that the privilege was founded upon considerations of public policy in the administration of justice in the courts. Attorneys were a part of their system, while physicians were no part of that system, and while the compulsory examination of lawyers as to communications received by them from their clients would tend to discourage confidence between client and attorney and to the suppression of truth in litigation, the disclosing of confidences given to physicians could in no way tend to weaken the administration of justice or to render it ineffectual.

The hardness and inequality of this rule, and the danger which was liable to follow from a disclosure by medical men of what they learned from patients as to their past life and family history, and the cause and character of their injuries, diseases and the like, have led to what was believed to be legislative reform in this country, and statutes have been passed in many of the States and Territories restricting disclosures by physicians of information received by them while acting in their professional capacity. Up to September 1895, the following twenty-five States and Territories had statutes of this character, viz., Arkansas, California, Colorado, Idaho, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Montana,

Nebraska, Nevada, New York, North Carolina, North Dakota, Ohio, Oklahoma, Oregon, Pennsylvania, South Dakota, Utah, Washington, Wisconsin and Wyoming; while in the other States the rule of the English common law is still followed and there are no restrictions upon such disclosures.

In many of the States there is a declaration of the policy of the statute prefixed to it, and this declaration is to the effect that there are particular relations in which it is the policy of the law to encourage confidence and to preserve it inviolable, and that, therefore, the prohibition of the statute is laid.

In California, Idaho, Minnesota, Montana, North Dakota, Oregon, South Dakota, Utah and Washington, the statutes are made to apply solely to civil actions. The statutes in other States make no distinction between civil actions and criminal actions. In some States, for example in New York, the statutes permit of a waiver of the privilege after death of the patient by his heirs or next of kin. In other States the power of waiver dies with him, and no one has the power of waiver after his death.

In Arkansas the information must be a *confidential* communication. (Collins v. Mack, 31 Ark. 684.) But in other States the rule has received a broader interpretation, and the general tendency of the courts in those States is to give the statute broad scope and effect, and to bring within its restrictions every kind of information which the medical man gains while in attendance upon his patient about his case: and the proper test may be said to be whether such information would have been given him had he not been in attendance in a professional capacity. It, therefore, includes not only what the patient tells the physician as to the disease or injury, and as to the cause of the injury, but the physician can not disclose what he learns by his own examination and investigation, or from statements made by patient even in the presence of a third party.

Hence it has been held that admission made by a patient to his physician tending to show contributory negligence on the part of the patient at the time he received the injury, are not admissible; and a physician has been prevented from disclosing whether his patient said that the car on which he was injured was in motion when he received his injury, because the injury would be likely to be more severe if the car was in motion. (Reynolds v. Burlington C. R. & N. R. R. Co., 65 Iowa 152.)

The fact that the physician does not prescribe for the patient, or actually treat him, is immaterial, for the status operates upon the communication itself and the professional capacity and presence of the physician. "If the act is a professional act, it is within the scope of the law. *Medicus optimus medicamentum minimum* is the maxim used in one case to illustrate this point." (In the Matter of Freeman, 46 Hun. 458.) Chas. A. Boston: Article on "Privileged Communications," in Witthaus and Becker Medical Jurisprudence, New York, 1894.

It has also been held by the United States supreme court, that in cases triable in the United States courts in States where, by law, such communications are privileged, the U. S. courts will enforce, as a rule of evidence, the rule laid down by the statute in such State. (Logan v. U. S., 144 U. S. 263, Conn. Mut. L. Ins. Co. v. Union Trust Co. 112 U. S. 250.)

Having thus briefly explained the statutory regulations concerning such communications and their

scope and effect, the question suggests itself for discussion how far such rules apply to railway surgeons who, in the employ of their company, visit patients and gain information after an accident or injury, examining their cases and treating them in a professional capacity.

I have no hesitation whatever in expressing the opinion that a physician acting in that capacity and under such circumstances, although not strictly in the employ of the patient, necessarily gains his knowledge from the fact that his services are rendered in a professional capacity, and that, therefore, any knowledge or information which he obtains under such conditions can not be disclosed, except upon the express waiver of the patient during his life time, or, in States where that is permitted, by his legal representatives after his death; the single exception probably being that in an action against the physician for malpractice, if the patient testifies as to the manner of treatment, the physician is then at liberty to introduce his own testimony, or that of another physician, as to the facts thus put in issue by the patient. (Lane v. Boicourt, 27 N. E. Rep. 1111. See also, Winner v. Lathrop, 67 Hun. 511.) And the rule in California is that where a physician is cross examined by his patient, calling for privileged matter, the privilege is waived. (Valensin v. Valensin, 14 Pac. Rep., 87.) But in a recent case in New York it has been held that although a physician is compelled to sue his patient for the amount of his bill and the patient denies the employment, the physician can not testify to what he did or prescribed for the patient. In New York a very analogous case to the relations of railroad surgeon and patient occurred in the case of Grattan v. Met. Ins. Co., 24 Hun. 43; same case on appeal to the court of appeals, 92 N. Y. 274, where another person employed a physician to examine the patient and report, and it appeared that the person examined did not desire any knowledge as to his condition; yet the court held, that, as the examination was made as a professional act, the relation of physician and patient was established between the physician and the person examined even though there was only an interview. In another case in New York the public prosecutor sent a physician to a person for the purpose of making an examination, so as to obtain evidence against another person charged with crime, and the person examined accepted the services of the physician in his professional character, and it was held that the physician could not testify as to the results of the examination. (People v. Murphy, 101 N. Y. 126.)

It is true that there have been other cases in New York, and perhaps in other States, which seem to vary this rule somewhat. In one case, for instance, where the physician stated that he was simply there at the instigation of another party to examine him, and not for the purpose of prescribing, and the examination was held in the presence of the patient's attending physician, it was held that the relation of physician and patient was not established. (Heath v. Broadway & S. A. Ry. Co. 8 N. Y. Supp. 863. See also Henry v. N. Y., L. E. & W. R. R. Co., 57 Hun. 76. People v. Kemmler, 119 N. Y. 580. People v. Sliney, 137 N. Y. 570.)

In Missouri it was held that information as to the way in which an injury was inflicted is of the greatest necessity for successful treatment, and that it is information which physicians invariably demand and receive, and should be excluded. (Norton v. City of

Moberly, 18 Mo. Ap. 457. Streeter v. City of Breckenridge, 23 Mo. Ap. 244.)

If the rule be as strict as I believe and have stated it to be it becomes a serious question for your consideration whether or not an effort should be made in the different States to have amendments adopted which shall modify the statutes somewhat in that particular.

Speaking as a lawyer, I am inclined to think that the rule as it now stands is a salutary one, so far as relates to ordinary diseases and mental and physical conditions; but that where a railway surgeon is furnished by the railway company and sent from place to place to treat patients without charge to themselves, if they knowingly accept his services and proceed to give him an account of the accident, and to disclose circumstances which would benefit the company by showing, in case of suit brought by him during his life time, or his representatives after his death, that he had brought the injury upon himself by his own fault, the rule ought not to be so limited and restricted as to prevent the disclosure of what is thus learned.

While it is in a general way, as has been said above, important and essential to know the nature and cause of the injury to enable the physician to treat the injury properly, nevertheless it is not so absolutely necessary and essential that perhaps the only intelligent and truthful witness whom the railroad company could call to show by the admissions of the patient how his negligence brought about his injuries, should be excluded from testifying. This is a question which is peculiarly one for your own good sense and good judgment to determine.

The theory on which admissions of a party to an action are admitted on behalf of his opponent, is that he would not tell what was against his own interests. For this reason Mr. Best, in his admirable work on Evidence, divides admission evidence into two classes, one of which he denominates "Self-serving evidence," that is, declaration of a party in his own interest, which is never admissible, and the other which he denominates "self-disserving evidence," being declarations made by a party against his own interests, which are generally admissible against him.

To weigh and determine this question properly, you ought to consider whether anything in the interest of humanity and of the well being of your patients would be concealed by them if they knew that you would be permitted to testify to it afterward. If so, then, the rule ought not to be amended, and you would be the last persons in the world to ask that it should be. On the other hand, if the probabilities are that in ninety-nine cases out of a hundred, nothing would be concealed or untruthfully stated because the patient knew that his statements could be used against him, and that you would be able to treat your case just as well and as fully and carefully and successfully, then the prohibition of the statutes, as interpreted by the courts, should be modified.

It is doubtless true that the dictates of what was believed to be sound public policy led to the establishment of these statutes, but their conditions have often worked a perversion of justice in the courts, and go into court to recover the amount due him for services; still in all statutory enactments in a free country, the test of the law must be whether it works the greatest good to the greatest number.

Apply that test to the statutes under consideration in this paper for yourselves, and no doubt you will

reach such a conclusion as will be eminently satisfactory to the dictates of professional etiquette, and to the duty that you owe to yourselves, your employers and to public sentiment.

THE BEST METHODS OF TEACHING.

Abstracts of papers read at the meeting of the American Academy of Medicine, Atlanta, Ga., May 4, 1896.

THE BEST METHOD TO TEACH PRACTICE OF MEDICINE.

BY J. C. WILSON, M.D.

The title of this communication has been selected by the Committee. The following method can not be regarded as "best" in any final sense, but as subject to alteration and modification according to circumstances. It is that employed in a medical school in which the speaker has the responsibility of arranging the details of the course in practice for large classes, and is the result of carefully considered progressive changes during a period of five years, starting with a systematic didactic course of three lectures a week and two general clinics a week. It is at present arranged for a three years' course. The four years' course to which it is now being adapted does not essentially modify the plan save in allowing the student more time for outside study and an increase in the number of hours devoted to actual clinical work.

The groundwork in physiology, visceral anatomy and the anatomy of the nervous system, histology, pathologic histology and morbid anatomy are preliminary to the course. The more thoroughly the student is grounded in these branches the greater will be his grasp of the subject of practice. The plan consists in systematic instruction in the following subjects:

1. Semeiology, including a discussion of the principles underlying physical diagnosis; one lecture a week, abundantly illustrated with diagrams, models, etc., delivered to the whole class of the second or third year, as the case may be.

2. Practical demonstration in physical diagnosis at the bed-side to the same class in sections. The sections vary in number according to the size of the class, but should not exceed fifteen men. The teaching is conducted by demonstrators, the roll is called and the work ranks in estimating the standing and progress of the student with section work in the laboratories.

3. Systematic didactic lectures by the professor of practice to the second and third or third and fourth year classes, as the case may be. This course covers two years. No effort is made to fully discuss every topic properly coming under the head of Practice of Medicine, on the contrary the consideration of very many diseases is brief and that of still more is omitted altogether. Important diseases, such as enteric fever, pneumonia, variola, diphtheria, malaria, endocarditis and pericarditis, blood diseases, the apoplexies, tabes dorsalis, forms of neuritis, epilepsy, chorea, hysteria, peptic ulcer, gastro-intestinal catarrhs, hepatic cirrhosis, visceral cancer, nephritis, diabetes mellitus, etc., are considered at length and in detail, an effort being made throughout to develop in each pathologic condition the interdependence of the morbid phenomena, the nature of the modification of physiologic processes to changes in structure, and stress being made upon etiology. The rationale of treatment is fully discussed. In advising therapeutic measures the lecturer invariably invites the attention of the student to the prin-

ciples involved. Available knowledge as to the natural history of disease is set forth. The discussion of differential diagnosis affords the opportunity for the consideration at some length of the morbid phenomena of associated and analogous disorders. It follows that such disorders may subsequently be more briefly considered to the saving of time and with no loss to the student. Thus, after a thorough study of enteric fever such less common febrile disorders as typhus and relapsing fever may be more concisely taught, or after such a study of pneumonia the consideration of bronchitis, broncho-pneumonia and the various forms of pleurisy may be made relatively brief, after variola the study of the other exanthemata may be condensed, and so on through the list. These lectures are fully illustrated by modern diagrams and models; nor is the use of the blackboard overlooked.

To those who object to teaching by lecture it may be said that this method has the advantage of a broader and more systematic exposition of the facts of medicine than any clinic, no matter how ample the material it can supply; that it is more suggestive and interesting than text-book quizzes, and that it invests the instruction with more or less of the personality of the teacher, according to his gifts.

4. During the two years occupied by this course two quizzes a week, forming part of the curriculum, are conducted by well trained competent demonstrators. One of these gentlemen quizzes upon the subjects of the immediate course during the week, the other upon the subjects of the course of the preceding year at the corresponding period. This arrangement gives the students at the same time a systematic and progressive review of the work of the two years.

5. General medical clinics are conducted twice a week in the amphitheater of the hospital, during the first half of the term by the professor of practice, during the second half by the professor of therapeutics. These clinics are attended by the members of the second and third or third and fourth year classes, as the case may be. From time to time they are conducted in the form of clinical conferences with students to whom cases have been assigned for especial study.

6. Special clinics on diseases of the nervous system, diseases of children, diseases of the skin and other subjects closely allied to the practice of medicine are conducted likewise in the amphitheater of the hospital by the clinical professors of the respective branches on certain days in the week. These clinics are attended by the students of the final year.

7. Ward classes for the study of clinical medicine, arranged for sections of the class during the final year. Attendance upon these classes is compulsory and has an equal value in making up the student's standing with section work in the laboratories.

8. Clinical microscopy, including practical urinary analysis, the use of the microscope, the staining of bacteria, etc., with especial reference to particular cases, is taught to sections of the class during the final year.

The purpose of this plan is not only to lay before the students the facts of *Inner Medicine* at sufficient length, but also from the most varied points of view; to familiarize him with those facts by constant repetition and renewed emphasis; to excite his interest and scientific curiosity in them by suggesting their analogies, relations and interdependence; and finally, to teach him the first steps of a technique in which training alone can make him an adept.

THE BEST METHOD OF TEACHING PHYSIOLOGY.

BY CHARLES D. SMITH, M.D., PROFESSOR OF PHYSIOLOGY, BOWDOIN MEDICAL COLLEGE, PORTLAND, ME.

What kind of physiology is it desirable to teach? Physiology of the human body. For what purpose is this to be taught? To place within the reach of the student facts which he may utilize. To accomplish these ends is a problem, the solution of which must vary with the average type of the class, the school, and the method of teaching employed.

Deficient preliminary education is fatal to a proper understanding and appreciation of the principles of physiology. A plan which seems to the writer to meet the requirements of the problem in the average school with the average students is outlined herein. The course should extend over at least two years. During the first, a knowledge of the functions of nutrition and reproduction should be acquired. He should, at the first, be made familiar with a comprehensive view of the chemie basis of the human body and the general properties of the muscular and nervous tissues, the functions of the cell, etc. During the second year, after reviewing the work of the first, the nervous system and special senses should receive special attention. Examinations should follow each year.

The advantages of this arrangement are: The student is given no more than he can fairly digest, his mind is not overcrowded or confused, he is not apprehensive of a final examination, and the course is progressive.

Instruction in gross anatomy and histology of the tissues and organs should precede the study of physiology. Experience in this two years' course has demonstrated its superiority over the plan which permits finals at the end of a single year.

The instruction may be given either by text-book, laboratory demonstration or didactic lecture. Each has its share of usefulness, no one is sufficient. The first is the most indispensable if the recitation is conducted along pedagogic lines. As to laboratory work, less need be said about *what* to demonstrate than *when*. It must supplement mental drill which has been obtained elsewhere. The lecture taken alone as a means of teaching may be objected to, its prime function is to supplement and enforce the teaching from the text-book and laboratory. A tendency in all departments of medical teaching is to crowd a certain amount of work in a certain space of time and to give weight to unimportant minutiae. The desired end of imparting knowledge is much more easily accomplished by placing before the student a general idea and filling in details afterward.

Summed up, the writer would urge: 1, a composite plan of recitation, laboratory and oral instruction; 2, less complex topics for the first year with three hours in the class room and one in the laboratory; 3, in the second year, two hours in the laboratory and one in the class room; 4, purely experimental work elective as an advanced study.

THE BEST OUTFIT FOR MEDICAL STUDY.

BY F. H. GERRISH, M.D.

In addition to the branches generally taught in the common schools, the would-be medical student should have a good command of English, a reading knowledge of easy Latin, and familiarity with French and German. Arithmetic, algebra and geometry are necessary. Physics and chemistry are required as a pre-

lude to physiology, and botany and comparative anatomy should precede human anatomy. Logic is an important branch. Wherever it is possible there should be practical laboratory work, and the habit of note-taking should be cultivated. In this connection it was insisted that drawing ought to be required, on account of the invaluable aid which it gives the student, the physician and the surgeon. No one should be encouraged to study medicine who is not physically strong, of fair natural capacity, fond of biologic work, and morally pure.

MEDICAL LONDON.

NOTES FROM MY SKETCH BOOK.

BY L. HARRISON METTLER, A.M., M.D.

CHICAGO, ILL.

While a student abroad, I had the opportunity of observing something about the medical side of the *Nation of London*, as De Quincey loves to call the world's metropolis, that may be of interest. The hospitals, as a rule, are quite ancient affairs, patched up here and there, and occasionally enlarged by the addition of new buildings. Guy's and St. Bartholomew's are among the oldest and most honored, while St. Thomas' and Queen's Square are among the more modern and elegant. The museums of most of them are exceedingly rich. The poor wretches who die within these hospitals often leave a legacy: sometimes only a leg, to be pickled in alcohol or corked tightly in a jar and set away on a shelf for the edification of zealous students and the admiration of note-taking travelers like myself. On account of the antiquity of many of these hospitals the lecture rooms are small, musty-smelling, cramped and uncomfortable. Is it any wonder that antisepsis should have had its rise in England? The great Lister himself was once a promenade through some of these musty buildings. Evidently something had to be done. The broom and the dust-pan only raised a cloud to choke one's lungs and to worry the sores upon the wretched patients. Perhaps a germ was lurking in all this dust. Let's kill him, we said, and dose him with bichlorids or carbolic acid or any other available thunder and lightning! We did and hence arose the antiseptics, the sprays, the washes and all the rest of the business. In some of the newer hospitals, especially in America, it was discovered that sometimes a flood of clean water, especially if it were boiled, got those germs out of the way about as well as all the thunder and lightning; which made it appear as though the dirt itself and the musty environment *tout ensemble* were the originators of those septicemias, blood poisonings, etc., which made the surgery of days gone by almost a curse rather than a blessing. So, in all things, we go on improving, learning some new facts and doing a great deal of loud crowing over our new knowledge and our wonderful discoveries, while in the end we find that we have only learned perhaps to be a little more cleanly and less filthy than our unsouped forefathers. The laboratories of nearly all the schools and hospitals are well furnished, roomy and adapted to the changed conditions in the study of modern medicine. What with wash-bottles, beakers, Bunsen burners, test tubes, reagents and germicides, with microscopes, spectrosopes, lactometers, urinometers, pulsometers, sphygmographs and a host of other harrowing apparatus and scientific complications, any country lad who comes up to study medicine

ought to be glad to pay his fee, gulp down the knowledge doled out to him and leave a wiser man, or at least a better self-estimated one, than when he arrived. What the laboratories make up the lecture rooms are abundantly deficient in. Their poor illumination is enough to inspire another divine comedy. Their stiff-backed, uncushioned benches possess a surprising faculty for raising boils on —, well, we'll say the elbows; but, perhaps, that has its advantages, for the student soon has a practical subject in himself and in his own *boiling* condition to begin his medical freaks upon. Having now paid my compliments to the hospitals of London in general, I will refer to two of them in particular, one a very ancient general hospital, the other a very new special one.

Under the first Henry, surnamed Fine Scholar, England began to recover from the civil conflicts that had been going on since the advent of the Conqueror; and London in particular was beginning to show the effects of the calm in the foundation about this time of some of her greatest buildings. In 1123 Rahere, the king's minstrel, established the hospital and subsequently raised the priory of St. Bartholomew beside Smithfield. In two inscriptions seen upon the walls of the hospital to-day, 1102 is given as the date of its foundation. This error has been traced to a careless transcription occurring in a fifteenth century copy of the life of Rahere written in the twelfth century. The hospital enjoyed an independent constitution and a separate estate, but like many hospitals of the present day was under the control of the religious organization. At first it had a head master, eight brethren and four sisters. From the beginning it was strictly a hospital for the sick and not an almshouse. This is distinctly expressed in the grant of privileges made to it by Edward III. Among the list of its benefactors are to be seen the names of Thomas à Becket, Henry FitzAilwin, the first mayor of London, William Longespée, one of the witnesses of Magna Charta, and King Henry III. The hospital and the priory were separated upon the dissolution of the latter in 1537. During the general religious upheavals under Henry VIII the king acquired possession of the hospital and its revenues, but upon the earnest entreaty of Sir Richard Gresham, Lord Mayor of London, he refounded it by royal charter, and in 1547 granted it another charter, which restored to it the greater part of its revenues. At this time it had 100 beds, a number which has since been increased sevenfold. The "*Breviarium Bartholomei*," a general treatise on medicine, was the first book to be written upon observations made in the hospital, and its author was John Mirfeld, one of the canons of the priory, living in the latter half of the fourteenth century. The immediate superintendence of the hospital for many years was placed in the hands of Thomas Vicary, sergeant surgeon to Henry VIII, Edward VI, Mary and Elizabeth, and the author of "*The Englishman's Treasure*," the first work on anatomy printed in the English language. From 1609 to 1643 Harvey, the discoverer of the circulation of the blood, was the physician in charge. Some of his rules in regard to the kind of cases which ought to be admitted are in force to-day. The great fire spared the buildings, but they were nevertheless reconstructed by Gibbs in 1730.

Availing myself of the special invitation of Mr. Bowlby, I was glad to witness within the walls of this famous old hospital so serious an operation as the tying of the innominate artery by Mr. Langton. A feeling

of laudable pride went through me as I passed through the gate where the immortal Harvey entered, and stood in the hall where the gruff old Abernethy used to lecture and where the unequaled anatomist, Richard Owen, wrought and revealed anew the antediluvian world. Above the portal still stands the statue of Henry VIII, fat, straddling and menacing. The hospital consists of a square of solid stone build-

suddenly revived. I could then and there have taken a hand at a tug-of-war, joined in the college cry or debated with the fellows the merits of the last senior oration. I pity the man who has no college reminiscences.

After making a few inquiries I came to the operating room, in which were gathered about a hundred students, twenty professors and lecturers and several

ings in the midst of one of the busiest and noisiest sections of London. In the center of the square is a large court, by shaded immense old trees, beneath which the students congregate for discussing a case from one hall to another. Upon entering this sedate old courtyard all my pleasant memories of college days were

nurses and attendants. Antiquity, of course, excuses a great deal, but I was a little disappointed at the smallness of the room, its poor ventilation and not over-cleanly appearance. The students are not supplied with benches but must stand on an ascending series of semi-circular steps, extending from the

operating table up toward the back of the room, and each supplied with a railing upon which to lean while witnessing the operation. During a long operation it is most exhausting for the men to stand thus crowded closely together, and though it may keep them wakeful it is not conducive toward maintaining the closest attention. The men were marvelously quiet and orderly, and showed in their very manner the seriousness of the operation which they expected to see. Soon the patient was etherized and brought in upon the table. The surgeon, a large man with a Celtic physiognomy and a half-drowsy, tired air, delivered a kind of explanatory introduction, clear, concise and explicit, without any attempt at oratory or rhetoric. Close beside stood Mr. Savory, styled the "orator" of the medical profession of London. Students thronged his lectures upon anatomy, this proving that the dullness of a discourse does not depend upon the subject matter, but upon the speaker. The operation was done rapidly, neatly and successfully.

The clinical practice of St. Bartholomew's to-day comprises a service of some 748 beds. Of these 227 are allotted to medical cases, 353 to surgical, 26 to eye disease, 20 to gynecology and 50 to syphilitics. In 1887 the in-patients numbered some 7,433 and the out-patients 150,828. Confinements attended at home by members of the staff numbered 1,623. The college associated with the Hospital is recognized as one of the best in the world. Its actual beginning is not on record, but students commenced to attend the hospital clinics as early as 1662. Five years later they were assisted in their studies by the formation of a "library for the use of the governors and young university scholars." Percival Pott, whose pupil was the famous John Hunter, was a lecturer in the school. John Abernethy instructed in anatomy, physiology and surgery in the theater erected for him by the governors in 1791. He attracted such large classes, including such students as Benjamin Brodie and William Lawrence, that a still more commodious theater had to be constructed. After many improvements and enlargements the steady growth of the school induced the governors to erect an entire set of new buildings in 1876 upon an enlarged area. In 1843 a college was founded to afford the pupils the moral advantages, together with the convenience of a residence within the walls of the hospital. It has since been enlarged to twice its original size. Within the court is the church of St. Bartholomew-the-Less, which was restored in 1865. The visit of an American physician to London would be incomplete without including a visit to St. Bartholomew's, for it is the most typical of the older London hospitals, as its staff contains the names of some of the most distinguished medical men of the day.

It is a novel experience to pass at once from old, historic St. Bartholomew to the new and magnificent hospital for nervous diseases in Queen's Square, Bloomsbury. This institution, christened The National Hospital for the Paralyzed and Epileptic, entered into existence in the year 1859. For twenty-five years its work was carried on in old houses. The foundation stone of the first part of the new hospital was laid by the Duke of Westminster in 1880. In 1883 the main building was started; it was completed in 1885, opened with royal ceremony, and dedicated as a memorial to the Duke of Albany, who took an active interest in the work but died before its completion. It is the first hospital for the treatment of nervous

diseases erected in any part of the Queen's dominions. Its books record the homes of some of its patients as Australia, South Africa, Hindostan, New Grenada, Trinidad, Greece and Sicily. Its world-wide reputation is readily understood from a glance at its medical staff which includes such names as Drs. Ramskill, Radcliffe, Hughlings Jackson, Buzzard, Bastian, Gowers, Ferrier and Messrs. William Adams and Victor Horsley. The annual expenditure approaches £12,000, more than two-thirds of which is made up by voluntary offerings, legacies, endowments and interest-bearing subscriptions. Subscribers have certain privileges for the admission of non-paying patients, but no one is treated gratuitously who is at all able to pay anything. Special wards are provided for middle class patients of straitened means, who contribute 21s. per week. As nervous diseases are so often incurable, it is a happy coincidence that a pension fund should be established in connection with the hospital. A benefaction of £300, for instance, founds a pension of £10 in perpetuity, one of £600 a pension of £20, etc.; and the founders retain the right of appointing the first pensioner, or reserving the nominations during their lives.

A description of the superb architecture of this hospital, its chaste and elegant fittings, its completeness of detail, would consume more space than is now at my disposal. Suffice it to say, that all its appointments are strictly up to date. For example, there are six hydraulic elevators, three for passengers, and as many more for the distribution of food, fuel and ward necessities; the corridors, staircases, halls and landings are wide, cheery, paved with mosaic, daintily distempered, and endowed with beautifully stained and tinted glass in doors and windows. Every dormitory has a large day room attached to it, supplied with piano, well-stocked library, games, musical boxes and other means of entertainment. The chapel is a beneficent consideration for a hospital in which many patients are obliged to stay many weeks or months. It is a charming room, covered with a handsome glass dome exquisitely tinted, and supplied with large a pipe organ and seating capacity for 120 persons. The chaplain and organist are paid out of a special endowment. The garden, though limited in area, is under a high state of cultivation, and by means of its pavilions and settees give the inmates an opportunity to enjoy the open air. Ever since 1868 a regular course of winter entertainments at fortnightly intervals has been annually organized. These performances have always attained a high standard of excellence. Under the presidency of the Duchess of Teck, the Samaritan Society, administered by a committee of ladies, attempts to provide the more necessitous out-patients with grants of fuel, food, clothing, to pay their fares to and from the hospital, and to send convalescents to the seaside and elsewhere.

There is a clinical amphitheater in the hospital, and here, as well as in the wards and dispensary rooms, many physicians from all parts of the world have availed themselves of this unrivaled field for the study of nervous diseases. It was my privilege, through the kindness of Mr. Adams and Dr. Ferrier to observe the work of this hospital for several weeks and I am grateful to add my testimony to the skill and ability of the staff in imparting knowledge, to the wealth of clinical material here to be seen and to the uniform courtesy shown by the attendants. In 1895 no less than 844 patients were received into the wards of this

special hospital. Of these 51 died while 556 were relieved or cured. Of the total number of fatal cases, 33 per cent. were cases of tumor of the brain, mainly of a malignant nature. Of the cases of epilepsy, 72 per cent. were relieved. The total number of patients upon the hospital book at the close of 1895 was 5,243, of whom 179 were in the wards. The remainder were either out-patients or were waiting for beds. As all forms of nervous diseases, organic as well as functional are admitted to this hospital, and as most of them, for obvious reasons, were major cases, it is easily seen how valuable an opportunity is here presented for the study of these obscure maladies.

Of the other great hospitals of London, mention might be made of Charing Cross, King's College, Brompton, Middlesex, London, St. George's, St. Thomas', Guy's, and Soho Square Hospital for Women, but time and space will not admit of a description of them here. The two I have selected are quite typical, each in its own way. Even these have occupied so much space that I can not now refer, as I had intended doing, to some of the medical societies, their meetings which I have attended, the medical schools, and a few of the medical customs of the private practitioners, differing from our own.

4543 Lake Ave.

DISCUSSION ON ADDRESS OF THE CHAIRMAN, DR. WILLIAM E. QUINE, OF CHICAGO.

In the Section on Practice of Medicine, American Medical Association,
Atlanta, Ga., May 5-8, 1896.

[Address appeared in JOURNAL of May 23, page 1012.]

DR. J. T. PRIESTLEY, of Iowa—With regard to the so-called Woodbridge treatment of typhoid fever, I made a report to our State society two weeks ago. For some time I had been impressed with the idea of intestinal antiseptics, and, in fact, got my first impression from Dr. George B. Wood. Dr. Wood, however, made the fatal mistake of blocking up the bowel with opium. Then came Birney Yeo's so-called chlorin treatment, for which he gave me the formula. Under that method I treated thirty-seven cases of typhoid without a single death. I judged at that time, as I do now, that the typhoid which we have been having through Iowa has been of an unusually mild character. Having had a personal knowledge of Dr. Woodbridge's work, I employed his treatment in forty-one cases of typhoid which I reported before the State Society of Iowa. Only two of that number died, and both of them were persons whom I did not see until the second week, and both were alcoholics. That is a much better result than I have ever been able to obtain with any other plan of treatment. I quite agree with those writers who regard the Brandt treatment of typhoid fever as a marked advance, but the inconvenience of applying it in general practice, together with the utter abhorrence for it which some patients experience, led me to try the Woodbridge treatment.

DR. BURNS, Philadelphia My attention was called to the Woodbridge treatment some two years ago, and being a resident of that portion of Philadelphia which is supplied with water that always, probably, contains typhoid bacteria, and where we are accustomed to seeing more or less of typhoid fever, the idea came to me, suggested by the Woodbridge principle, to use carbolic acid as an antiseptic, in conjunction with glycerin as an eliminative. I regret that I have not kept a full record of the cases treated in that manner, but in a considerable experience I have met with no deaths, and although the temperature had been high, 103 to 104 F., pulse rate 100 to 120, tongue dry, diarrhea, the course of the disease was modified and ended in recovery.

DR. HOBART A. HARE, Philadelphia Whether we believe in

the theory of antiseptics in the treatment of typhoid fever or not, I think we recognize the fact that in those instances in which we combine with this treatment the use of hepatic stimulants, or drugs designed to increase the activity of the liver, we do as much toward modifying the severity of the disease by preventing the absorption of toxic material as we do by producing actual intestinal antiseptics. In a number of diseases which we suppose now to be largely due to a septic condition of the alimentary canal, and in which the systemic symptoms are out of proportion apparently to the local lesions—for instance, the summer diarrhea of infants—I have found that the administration of drugs like podophyllin produces improvement in the condition of the patient in direct proportion to the increased activity of the hepatic gland. I believe that physicians are too apt to consider that the only function of the liver is to pour out bile into the alimentary canal. The result of that function is, of course, that the bile acts as an antiseptic in preventing putrefaction, but we forget that the liver has a very important function to perform aside from its glycogenic function, namely, the function of destroying poisons which are absorbed from the alimentary canal. If the blood vessels leading to the liver are tied off in such a way that materials can be absorbed from the intestine without first passing to the liver, it has been found that the animals become rapidly intoxicated. And if poisons be given to animals from which the liver has been extirpated, or in which the liver has been prevented from acting by mechanical means, it has been found that very much more minute doses of those poisons will produce death than in animals in which the liver has been left intact. Now, if podophyllin, which we have heard of in this antiseptic treatment, does good, it does good, I think, by its influence upon the hepatic gland. The hepatic gland in its turn probably acts just as any large capillary network may do, by destroying toxic material in the circulation. The liver being a particularly large collection of capillaries, has unusual power to destroy vegetable alkaloids, as shown by experiments, and, in a similar way, probably destroys those toxic agents which enter the system from the alimentary canal. Now, my experience with the treatment of typhoid fever is small and the cases which I have seen have been mild ones, the death rate *nil*. I have employed practically no treatment except a little hydrochloric acid to keep the stomach active; clean the tongue, control excessive diarrhea or constipation, or meet any other individual symptom which might arise. But in another disease which I have already mentioned, the summer diarrhea of infants, again and again have I seen this effect of stimulating the liver. In the sanitarium at Red Bank, New Jersey, a large number of cases have been studied, of children brought there while purging a peculiar watery material, of mousy odor, passing rapidly into collapse, and on giving minute doses of podophyllin every hour or every half-hour the passage would be seen to assume a biliary color, and with the first sign of return of hepatic action we were safe in giving a favorable prognosis. I repeat, that where these drugs do good, I believe it is quite as much by increasing the activity of the liver as by any intestinal antiseptics which they may develop.

DR. JOHN A. OUCHTERLONY, Louisville—I was very much interested in the paper, and not at all less so with the first part of it than with the second, but inasmuch as the discussion has turned chiefly upon the latter part I wish to make some remarks upon that. When I began the study of medicine the principal object which we had in view was to support the patient's strength. Very little else was aimed at except to meet complications or symptoms as they arose. But after awhile it seemed to me that was not all that might be done, especially in as much as we find the type of typhoid fever vary exceedingly. It is almost impossible to lay down one mode of treatment of this disease when one epidemic is so unlike another. It is true that during the last few years the epidemics

which we have passed through have been of a milder type than those of fifteen or more years ago, but I have noticed that in those cases in which there was actual constipation or very little diarrhea, the temperature was likely to run much higher than in those in which the diarrhea was moderate, and that pointed rather clearly to the fact that diarrhea is eliminative and therefore conservative, so that I came to regard it as a good plan to help nature by increasing elimination where the bowels were constipated, and even in cases in which they were not constipated. I have been particularly struck by the fact that the less the bowels perform the eliminative function the higher the temperature is apt to run, and that, instead of giving antipyretics for the reduction of the temperature, we may often accomplish that desirable object by making the bowels do their eliminative work and thus remove from the system the fever-exciting poisons agents. As to intestinal antiseptics, I began giving attention to this a few years ago, and while I must say that I have not had remarkable results, still the plan has certainly worked well. The reason that I have not seen any very great difference between the cases treated and those not treated with antiseptics is probably due to the fact that the epidemics were mild, the cases were not severe, the temperature was not excessively high, and the other leading symptoms were mild in proportion. The sulpho-carbolate of zinc has been the agent which I have chiefly relied upon, and I can not help thinking that hydrochloric acid, which we have been using for so many years and with apparently good results, when given persistently and in full doses must certainly produce some antiseptic influence. I do not look upon it merely as a placebo, but as a remedy of positive usefulness in the treatment of typhoid fever.

DR. KRAUS, Iowa—Since we have heard a little report from our State on the antiseptic treatment of typhoid fever, I would like to state that during the year I have treated seven cases in this manner with two deaths. Never before had I two deaths in one year, while I have treated as many as forty-three successive cases without one death on the general plan mentioned by Professor Hare. The first case which I treated by the Woodbridge plan, as far as I could, was that of a strong young man not an alcoholic, who kept at his work for a week after the beginning of his illness, and then came under my care. I employed the tablets and the capsules, but principally the latter. He had a severe hemorrhage within three or four days after the commencement of the treatment, and although he lived three weeks from this time yet he continued to have hemorrhages off and on until death. Then I had two cases recover after about two weeks sickness. The next case I saw early, carried out the treatment with medicines put up by Parke, Davis & Company, and he died at the end of seven or eight days. I may say that one of my colleagues who treated three cases in this manner lost one of them.

DR. H. A. WEST, Galveston—I consider this subject one of the most important ones which could come up for discussion before this section for the reason that, if the claims made for his treatment by Dr. Woodbridge should be substantiated by the accumulated experience of many observers, he has in my opinion, made one of the greatest discoveries of the age. It has been claimed that by this treatment typhoid fever can be aborted; that it can be cut short in a few days, and that now we should not have a death from this disease, or at any rate very rarely; in other words, that we have a specific for typhoid fever. I repeat that if this can be substantiated, then one of the greatest of all discoveries has been made. As far as I know, no other remedy with any such power has yet been found, and I must confess that I have been extremely skeptical in regard to this one. It seems to me that several things should be taken into consideration. How many specifics have we for infectious diseases? What specific have we for scarlet fever, for cholera, or for other infectious diseases? But I do not propose to be satisfied with excluding this new remedy

because I do not believe in the principle of its application. I intend to try it. Thus far I have contented myself with treating cases of typhoid fever largely on the expectant plan, giving antiseptics only so far as they did not interfere with digestion, produce nausea, take away the appetite, or interfere with any of the functions of the body. In view of the explanation which has been offered of this Woodbridge method, that it is eliminative, it would seem there may be something in it, but so far as the claim is made for it—of cutting short the disease and reducing the mortality to so great an extent, I must confess that I am a skeptic. We frequently see cases of typhoid fever which have gone to the second week before entering the hospital or calling a physician, sometimes perforation has first occurred, and I repeat that I am skeptical as to the discovery of a specific for this disease.

DR. LANGTHY, Pennsylvania—I live in a city where it has been said we have more typhoid fever than anywhere else in the United States. I believe in the antiseptic treatment of typhoid fever. I have treated 300 cases, of which I have kept notes, about two-thirds of them with the Woodbridge treatment and about one-third of them with naphthalin used as an antiseptic. The mortality has been 3 per cent. I do not believe the Woodbridge treatment is any better than the naphthalin. About two hundred grains a day of naphthalin will do anything which the Woodbridge treatment will accomplish, and just as effectually. In collapse during typhoid fever the injection of normal salt solution acts better than anything else.

DR. WITHERSPOON, Nashville—So many of the gentlemen who have spoken have favored the use of the Woodbridge method of intestinal antiseptics in typhoid fever that I think it is about time for some of us who do not believe in it to say something. In the first place, I do not believe that the pathology of the disease warrants the cure which it is said to effect. The period of incubation of typhoid fever is really the time when the germ is invading the alimentary tract, and it has found the proper nutriment for its development in the lymphoid structure before we see the case, before the development of symptoms and the diagnosis of the disease. Now, after the germs have penetrated the lymphoid structure, I claim that intestinal antiseptics can not accomplish much, if anything, in the treatment of the case. I do not see how it can. I thoroughly agree with Dr. Hare that, like the use of podophyllin, an increase of secretion is about the only thing there is in the treatment. How we can use a minute quantity of an antiseptic in the treatment of a disease which has already passed into the lymphatics of the body, which is already being eliminated by the urine, which has already involved the spleen and liver, and cut it short, I certainly can not understand, and I do not see how we can promise ourselves anything more by that method than by any other. Another thing seems remarkable to me, and that is that the gentlemen should have seen so many cases of typhoid fever. It is certainly different from my experience. I do not doubt their statistics, but I do doubt the diagnosis. We know well that there are forms of continued fever which simulate very closely typhoid fever and yet which have not the specific germ of that disease, and I would like to know, of those who have spoken, whether in their cases the specific germ was found. Where such remarkable results are obtained apparently from the treatment, it is important to know whether the diagnosis was beyond doubt. I believe the Brandt method is by far the best, and that it has given the best results in the treatment of typhoid fever.

DR. N. R. COLEMAN, Columbus, Ohio—This subject is of such deep interest to all parts of the country that I hope to be excused for taking up a little of your time. The interest is not confined to the medical colleges, for we hear gentlemen from all parts of the United States giving their experience, or their views, on this method of treating typhoid fever. Before expressing my own views I should like to ask Dr. Priestley

whether he treated his forty cases strictly and absolutely on the Woodbridge principle, or did he carry out a mixed treatment?

DR. PRIESTLEY I treated them according to that plan, to the best of my ability and as strictly as I could. I did not test for the bacillus.

DR. COLEMAN Did you follow the Woodbridge diet?

DR. PRIESTLEY No.

DR. COLEMAN I am an Ohio man and have heard Woodbridge speak. He will tell you that he allows his patients to eat almost as they did before they had typhoid fever. They can eat gross food. He will tell you that he will put the patients on their feet in fifteen days. I have had occasion to say that I do not believe it. When you take one specified kind of treatment and say that it is a certain means, and that it must be adhered to to the letter in every case, I do not believe there is a gentleman present who has the rashness to adopt it, who will in typhoid fever give these intestinal antiseptics and allow their patients to eat gross food from the onset, giving beefsteak and even cabbage, as I heard stated in Ohio, and claiming to get patients up and about their vocation in from nine to fifteen days. It is with such claims that we have to contend, and I may say after carefully studying the histories of their cases and looking over the temperature curve, I have become a doubting Thomas as to their diagnoses. I do not believe their diagnosis is correct, that it is genuine typhoid fever, but rather that the majority of the cases are cases of remittent fever. I do not believe that they have to deal with the typhoid bacillus and the toxins and ptomaines that are generated by that germ. Before giving my limited experience I would like to call your attention to a few things. You are called to a case of true typhoid fever, and the very first thing which may strike your attention is a congested condition of the skin, showing evidently a vaso-motor paresis. Your patient is entering semi-coma. He is carried into the hospital in that condition. I remember that last fall four cases were brought into the hospital in that condition, and they require prompt and determined treatment or they will die. Another case will have backache, general malaise and constipated bowels for a week or longer before you are called. In another the bowels are loose and the greatest trouble you have to contend with throughout the entire disease is to control the bowels. The cases of typhoid fever which give the least trouble are those in which the bowels are more or less constipated. The cases which have frequent action of the bowels are the ones which in my limited experience are most apt to have hemorrhage—a symptom which has killed more patients for me than all other things.

Consider again the idea of the Woodbridge treatment setting the patient on his feet, well, within fifteen days. Before you ever see that patient the germ has already entered the intestinal mucous membrane; it is already at work; the solitary glands and the Peyer's patches are in a state of congestion with enlargement; you may be able to eliminate more or less of the toxins and ptomaines which have been generated, but you can not return those glands to their normal condition in a short period of time. When, therefore, a series of cases is reported with such excellent results, we have a right to doubt the correctness of the diagnosis. In the central part of the United States we meet with many cases in which, without the aid of the microscope, it is difficult to differentiate between typhoid and remittent fever. I meet with such cases and I make use of the microscope. If you find the typhoid germ, you have something to base your diagnosis upon. Otherwise I should have serious doubts. I have employed the Woodbridge method, but in some of the cases I had to discontinue it on account of the frequent action of the bowels, for, as I have already said, where the bowel has been loose I have had more trouble in controlling it than with any other symptom. I have not been able to carry out the Woodbridge treatment in every respect on that account. It is too risky. For two years we have used the bath, in the Hospital, in every case when the temperature went above 102.5 F., and the records show that the mortality has been lower than during previous years. It is an invaluable treatment. In reference to intestinal disinfection, I am a believer in it. Do not understand me that I would not advocate elimination from the intestinal tract, for it is the great sewer of the body. I invariably start my treatment in typhoid with some agent which will produce intestinal elimination. I like calomel, podophyllin, or something of this nature, to start the secretions because I think it is a serious matter to allow a patient to go through a long sickness with the bowels clogged and take the chances of intoxication. So I repeat that alimentary disinfectants are useful, and I like the sulphocarbonate of zinc as well as any. It is a safe agent, and may be carried up to almost any extent without toxic effects. So, with the Brandt method, with proper diet, and

with intestinal disinfectants, the results have been satisfactory in a high degree, but I have never been able to cure a case of pure typhoid fever short of two to four weeks.

DR. FENTON B. TURCK, Chicago—The study of typhoid fever can not be carried out by simply enumerating symptoms, and it is impossible to discuss this question on the line of semiology alone. It is most difficult to make a diagnosis by bacteriologic means. It is a most difficult thing to differentiate between the colon bacilli and the so-called typhoid fever bacillus. However, we know something of the method of invasion among microorganisms of the alimentary tract. We know that they pass through the walls. In the Cook County Hospital we make a careful bacteriologic examination in every case of typhoid fever which comes to autopsy, and we find microorganisms in the spleen, in the liver, and various parts of the body. Can you call that a purely intestinal disease? Now with regard to treatment, bacteriologists would be rather loath to expect to disinfect a tube twenty-five feet long with a few grains of any antiseptic. We can not in a small test tube even, produce an aseptic condition with a few grains of any antiseptic. It is impossible, then, in this long intestinal tube to produce it by any of the various antiseptics used. Hence we can not, simply on the basis of antiseptics, reason out a treatment which will destroy the microorganisms, and such therapeutics are theoretical and irrational and should be discarded. If you say you do it empirically, it is all right; but if you do it for antiseptics it is wrong. If you give strong enough poisons to produce an aseptic condition you destroy the cells of the alimentary tract. Therefore it is irrational. Regarding the toxic effects in typhoid fever, I have watched them carefully, and while elimination of the toxins would be symptomatic treatment, yet it would be along the lines of our present knowledge of this disease. Dr. Hare has frequently in his writings called attention to the great importance of elimination through the alimentary tract. The Brandt treatment, as you know, has for its purpose the stimulation of the circulation by which the antitoxin of the blood, the blood within the viscera, is swept into the general circulation. Hence to increase the circulation is to increase elimination. I present these few ideas because time will not permit of giving long clinical experience. Your attention is called to the futility of attempting to disinfect a tube twenty-five feet long, like the intestinal tract, with a few grains of antiseptics.

DR. HOLTON, Vermont—For a hundred years typhoid fever was an annual epidemic in New England. Dr. Nathan Smith had more success in its treatment than any other man in the beginning of this century, and when asked what his treatment was, he said it was milk and water. He gave his patients plenty of water and nourished them on milk and treated symptoms as they arose. During the first fifteen or twenty years of my practice I was located in a vicinity where typhoid fever was an annual epidemic, and I could predict that when new people came into a certain neighborhood they would be sure to have typhoid fever. Now, those cases were typical, having all the symptoms laid down in the books, and the rule was, throughout that section, a mortality of one in forty. The treatment was expectant in those days. We were taught to nourish the patient on milk. When indicated, we gave our good old friend calomel, and when the tongue was brown we gave a little turpentine. During the last twenty years, under the same conditions so far as we know, it has been a rare thing to see an epidemic of typhoid fever in our community. We know that in the history of medicine diseases go by cycles. In the seventeenth century an epidemic of malarial fever went through New England. Fifteen or twenty years ago it again passed along essentially the same track as a hundred years ago, along the coast. We do not have it now. I have talked with physicians who tell me the same thing with regard to typhoid fever. We seldom see a typical case. The cases which we do see usually have symptoms only ten or twelve days. I treat them in the same way as typical cases, stirring up the secretions, for I believe in all diseases there is a great deal in keeping the glandular system of the body active with antiseptics, if you please to so call them, such as thymol or iodine, or whatever seems to be indicated, and patients get well. Now, we know there are what have been called perambulating cases of typhoid fever, and some of those patients continue to walk about until they have a hemorrhage from the bowel and die within twenty minutes from the time they are seen by the doctor. The Peyer's patches had ulcerated and caused hemorrhage from the branches of the mesenteric artery. The point which I wish to make is, that, while we see these changes in the type and in the frequency of typhoid fever for which I am unable to account, but simply note the fact, I am cautious about giving credit to any particular form of treatment for the

good results apparently obtained, when that treatment has no rational basis, for, as the last speaker has said, we can not render twenty-five feet of intestine aseptic with a few small doses of some disinfectant. Attention has already been called to the fact that before we see the patient the bacilli have infected the system.

DR. J. A. CROOK, Tennessee—I have been in the habit of reading this matter on typhoid fever ever since Dr. Woodbridge's first paper was published, but I had not used any of the remedies suggested until the past season, when I had occasion to treat twelve cases. The shortest duration in any case was eight days. The longest fourteen days, the average being eleven days. It may be questioned by some, however, whether I treated a single one of the cases by the Woodbridge method, for at the time I was called I did not think it necessary to risk disturbing the stomach every fifteen minutes and therefore omitted prescription No. 1 and began with No. 2. As soon as the bowel had moved freely I passed to No. 3. Prior to this experience I thought I had success in the treatment of typhoid fever with the Brandt method, with sulpho-carbolate of zinc, with salol, carbolic acid, etc., but never did I have results which compared with those of the past season. Cases have been reported from Massachusetts, from Denver, from Washington and elsewhere to the number of more than one hundred, and among all these reports there was but one death where the Woodbridge treatment had been employed, and in that instance it was due to hemorrhage which occurred a short while after eating fried meat, etc., contrary to directions. No other treatment yet discovered has given such success. I may report a case, that of a patient whom I found with a temperature of 102 degrees to 103.5 degrees, bowel distended, tongue coated, three or four passages a day, etc. He said he had been in that condition nearly a week, trying to wear the disease out. Whether it was typhoid or not, it was the same disease which we have been in the habit of treating for three or four weeks and regarding as bad cases of typhoid fever. I put him immediately upon the Woodbridge combination No. 2. Next day he was no better, but the treatment was continued, and on the third morning he said that medicine was helping him. Being asked how he knew, he said his actions were not so offensive. That man, without having heard an expression from me, had formed the conclusion that it was an antiseptic. The following day I gave him No. 3. No quinin, never a fever powder, but on the fifth day the fever began to recede. The eleventh day his temperature became normal, and he had no further trouble except swelling of one limb during convalescence.

DR. ALONZO GARCELON, Lewiston, Me.—I have been in practice over sixty years and arise to confirm the testimony of my friend Dr. Holton who says that the character of typhoid fever has changed during that time. I commenced the practice of medicine in the year 1839, and immediately after that, even in the State of Maine where we have clear water, pure air and seemingly every condition which nature has conferred upon mankind for health and long life, we had many cases of typhoid fever. But the disease at that time was always characterized by certain definite symptoms which all of you who have had much experience must recognize as belonging to typhoid fever. Among them were sudamina, dry tongue, diarrhea or constipation, tympanites, hemorrhage from the bowels in about one-third of the cases, fever, etc. A very considerable number of those with severe hemorrhage from the bowels recovered. The treatment in those days was very much as suggested by my friend from Vermont, regulation of the secretions, medicines intended to act upon the liver, upon the bowels, for tympanites eucalyptus. Now, the past ten or fifteen years I have not seen perhaps a single case of genuine typhoid fever. In the city in which I live I have seen a number of cases in consultation which were called typhoid fever, but which were simply a typhoid state of the system—not real typhoid fever. There was no sudamina, no rose spots, no tympanites, in short, absence of those symptoms which we regard, when taken collectively, as characteristic of genuine typhoid fever. Now, with regard to the statement that Dr. Woodbridge made, that you young men are guilty of malpractice and ought to be indicted and punished if you allow a typhoid patient to die—it is a very grave assertion. If, as has been asserted, this disease is found to depend upon a microbe which generates so rapidly as to be in excess within a few months of all the plants and shrubs upon the face of the earth, and if gray-haired men who have been in the practice of medicine so many years have not found any efficient treatment of typhoid fever, pray to heaven what has preserved their patients!

DR. HARDEN, Tennessee—When I read Dr. Woodbridge's treatment I sent and got some medicine of Parke, Davis & Co. Although I live in a section of country where during the summer

time I see on the average twenty cases of typhoid fever, I may say that since receiving this medicine I have seen only one case in which I felt certain of the diagnosis. There was no eruption, but then I seldom see the eruption in that section of the country. Having become convinced of the diagnosis about the fourth day, I immediately discontinued other treatment and put the patient on the Woodbridge tablet No. 2 every hour for twenty-four hours, then every two hours. The patient had no unpleasant symptoms and the odor of carbonate of guaiacol was very distinct in every movement. One point brought out by my friend from Nashville is worthy of consideration, namely that the bacteria have already entered the system when we see the patient. That is true, but if by antiseptics we can remove the nidus of those germs it seems to me we can do a great deal of good.

DR. MINOR, Ashville—In carrying out the treatment we should in order to test its real value follow the directions given by the author strictly. Now, none of the gentlemen have said anything about the diet. It seems to me that if Dr. Woodbridge favors solid diet and all of these gentlemen have modified the diet while they have only given one or two of these tablets, they can not get up here and say they have carried out his treatment.

DR. WM. OSLER, Baltimore—I had hoped to hear some remarks upon that part of the chairman's address which referred to the use of animal extracts in various disorders. Whatever we may think with reference to the bone marrow treatment of anemia, or of suprarenal extract treatment of Addison's disease, we must admit that the thyroid extract treatment in the class of diseases characterized by the loss of function of the thyroid gland is a positive specific. We have nothing to compare with it in the whole range of medication except quinin in malaria and iodid of potassium in syphilis. Take, for instance, a case of sporadic cretinism within the first five or ten years, or a case of myxedema in a woman who may have been helpless a long period, or a case produced by a surgeon removing the thyroid gland in toto, you can say positively that within from six weeks to three months there will be such a change in the patient as we are not accustomed to see under any other form of medication. I think, therefore, that the thyroid extract treatment comes upon an entirely different plane. It is used in congenital myxedema, in sporadic cretinism, in spontaneous myxedema, in the cachexia produced by removal of the thyroid, in all of which it acts as a specific. It was not my intention to discuss the subject of typhoid fever, but in view of the remarks of some of the gentlemen I must say that I have seen very few patients die whose bowels were constipated. If there is any one symptom which I dread it is diarrhea: if there is any one which I care little for it is constipation.

DR. PAUL PAQUIN, of St. Louis—It is my belief that the treatment of all microbic fevers rests on natural law after all. Whatever remedy we prescribe and whatever measure of treatment we apply, it must eventually act through nature's own forces in bringing about recovery. So with the Woodbridge treatment, which is supposed to act through its germicidal influence. Any remedy which may succeed in exalting nature's own forces in driving out the microbes and their products is certainly in the right line, whether it is calomel, or podophyllin, or whatever may be used. The same views apply to the use of animal extracts in myxedema, etc.

DR. J. B. MARVIN, of Kentucky—I think we should, in the language of the Congressman, ask where we are at? If you do not believe that typhoid fever is a specific infectious disease, then you can treat it empirically, make all sorts of claims about it, and we will not question your pathology nor your therapeutics. I occupy a position in a medical school, and am asked by students my opinion of the Woodbridge treatment, which I have learned about through Dr. Woodbridge's writings and hearing him speak. If I understand him aright, he claims that typhoid fever is a specific infectious disease, and by antiseptics he destroys the germs and cures the patient, so that we can discuss the method from a scientific standpoint. If that is so, we must appeal to bacteriology to get the life history of this germ. As stated by one of the speakers, this germ, after leaving the mucous membrane, invades in a very short time the lymphatic system and other tissues of the body, so that it is not lying on the surface of the intestinal tract where it can be washed off or reached by antiseptics.

When a man gets up and makes the statement that one who loses a case of typhoid fever is responsible, it is saying a good deal. I have practiced medicine a good many years, both private and hospital practice, and I do lose cases of typhoid fever, and I do not hang my head in shame on admitting it. We are all fallible. All that can come from such statements is to cause uneasiness on the part of the laity. Doctors say a child is threatened with typhoid fever, diagnosticate this disease in all

sorts of conditions, and get whatever results they choose. I do not believe a person is ever threatened with typhoid fever. He either has it or does not have it. I have never been ambitious to be enrolled in the list of abortionists.

Another thing: A doctor says he has seen twenty cases, and it appears that he has made his diagnosis very quickly. The first few days, I can not do it, and I question a diagnosis of typhoid fever made at the first visit. Can one, before the characteristic symptoms have appeared, make a diagnosis the first few days and claim to cure typhoid fever in from four to eight days?

Again, we must support these patients. The cause of the disease is bacteria, but can we give to a man antiseptics which will kill these germs? It is a delusion and a snare. I think intestinal antiseptics is a will-o'-the-wisp. It is turning the hand of progress back fifteen or twenty years.

DR. THOMAS, of Pittsburg, Pa. — I do not get up to teach any of these gentlemen how to treat typhoid fever. I have nothing new to offer, neither have I heard anything new offered. But some gentlemen do not believe in abortion. Now, if I had fever and ague, I would not engage the gentlemen to my left. We do abort a fever and ague, and why should we not make an effort to abort typhoid fever?

DR. STEWART, of Pittsburg — In 1890 Dr. ——— and I treated fifty-five successive cases of typhoid fever, not one of which ran a course of less than four weeks, and every patient got well. Another doctor near us had thirty-seven cases, all of which got well. I went abroad, came back in 1892, an epidemic of typhoid fever had broken out just before my return. The doctors in Pittsburg told me that out of, I believe, twenty-three cases, nine had died. They thought that, as I had been abroad, I would be able to cure these cases, so I turned my batteries upon them and out of eleven successive cases seven died. They said I ought to have stayed at home.

Now, the facts are just these: You may have twenty-five or thirty cases all run a mild course and get well; then you may have another series of cases which will die in spite of you. The same thing is observed in scarlet fever, and in other diseases. But I believe in treatment. That is all I have to say.

SOCIETY PROCEEDINGS.

The Association of Military Surgeons of the United States.

[Special Correspondence of the JOURNAL.]

The opening meeting of the Sixth Annual Session of the Association of Military Surgeons of the United States was held in the Broad Street Theater, Philadelphia, Pa., Tuesday, 10:30 A.M., May 12, 1896. Beside the officers of the Association and the speakers of the day, Professors John H. Brinton, M.D., William S. Forbes, M.D., and William Thomson, M.D., of the Faculty of Jefferson Medical College, in academic gowns were seated on the stage.

After an overture by the full band of the First Regiment Pa. N. G., and a prayer by Rev. H. A. F. Hoyt, Chaplain of the State Fencibles, Pa. N. G., the President of the Association, Colonel Louis W. Read, Surgeon-General Pa. N. G., formally opened the session, introducing the Hon. D. H. Hastings, Governor of Pennsylvania, who welcomed the Association in the name of the State, paying a generous tribute to the medical department of the National Guard of Pennsylvania, for its share in the splendid organization of that body, whose soldierly bearing has gained for it the designation of "Pennsylvania regulars," and which on all public occasions, when serving outside the State, has attracted equal attention and commendation with the United States regulars—results largely due to its efficient medical staff of which the President of the Association of Military Surgeons of the United States, Surgeon-General Read has been for over twenty years the official head.

MAJOR GENERAL GEORGE R. SNOWDEN, commanding the National Guard of Pennsylvania, then welcomed the Association in behalf of that body, recalling the pleasant relations, which have always existed between the medical officers and their military associates in the other corps. "One in particular, I remembered," he said, "who I always regretted had bound himself to the medical profession, for if he had not been so excellent a surgeon he would have made a magnificent commanding officer. Many others of them, in addition to ranking high in their profession have distinguished themselves in arms," instancing Warren, Montgomery, Mercer, Crawford and others. General Snowden declared "that civilization was gauged by the regard in which the medical profession is held," and concluded by expressing "the hope that at all times the two branches of the service, the medical and the non medical, should maintain the same pleasant relations as now exist."

THE HON. CHAS. F. WARWICK, Mayor of the city of Philadelphia, followed with the significant promise that "old Sol and I will make it the warmest welcome you have ever had in this city of ours."

BRIGADIER GENERAL THOMAS J. STEWART, Adjutant General of the State, specially represented the Medical Department, extending in behalf of the officers of that department a most cordial welcome, and assuring the Association "of the great joy, pride and honor we of the National Guard feel that you have selected our honored Surgeon-General, Col. Louis W. Read, to be your President. He has held the office of Surgeon-General twenty-two years, and has filled it ably and filled it well. We appreciate him as a man, and are proud of his magnificent record as an officer."

PROF. J. M. DA COSTA, President of the College of Physicians of Philadelphia, next welcomed the Association on the part of the medical profession, dwelling particularly on the fact that "medical men have always been regarded as indispensable to the proper conduct of armies. Esculapius himself served as an army surgeon, and his two sons, the Greek poet tells us, took care of the wounded before Troy. Greatly has the military surgeon ever been esteemed. Paré was handed down from one king of France to another as a precious legacy. The order directing him to the siege of Metz said, 'I send you my beloved Paré, equal to a reinforcement.' Larrey, picked up wounded on the field of Waterloo, was at once released and Napoleon's words in regard to him will pass on through centuries, 'to the most virtuous man I have ever known.' Washington refers in his will to Craig as 'my compatriot in arms, my old and intimate friend.'" Professor Da Costa then referred to the change in the nature of the duties of the medical officers. "At one time, indeed until recent years, he was much more occupied with disease than wounds. The army of Henry V. before the battle of Agincourt was reduced by illness from 59,000 to 10,000. Frederick the Great said that a single epidemic of fever cost him as many lives as seven battles. The havoc by illness alone in the Walcheren campaign is historic. In the Crimean War, the French lost by disease 70,375 as against killed by wounds 20,240; the Russians by disease 600,000, killed by wounds 30,000. During our own Civil War about 104,000 fell in battle or died of wounds, while over 186,000 perished by disease and 24,184 from unknown causes," a total of over 300,000 from causes not attributable to the enemy in arms—these latter amounting, in fact, to only one-third of those inflicted by that invisible, aggressive, powerful foe, whom only the medical officers and their subordinates had to combat. Professor Da Costa further stated that "the first time in modern warfare in which the proportion was changed was in the Franco-Prussian war, and was largely due to advancing knowledge in hygiene, and to the rigid enforcement of its rules. In 1870, out of a total of 40,382, only 12,180 were lost by disease and 28,082 by wounds, and in future campaigns it is the military surgeon and not the military physician who will be most at work, provided, however, the lessons of sanitary experience are heeded, and the commanding general understands that by taking and acting on enlightened advice he can save enough of his army to prevent defeat or to turn indecisive engagements into brilliant victories. Referring to the increased risk of the modern military surgeon, Dr. Da Costa stated that *three hundred and thirty-six* regular and volunteer medical officers were killed in battle or died of wounds, accidents and disease during our Civil War, at Gettysburg alone thirteen medical officers having been wounded "a proof of their heroism and devotion." During the recent hostilities between China and Japan, the casualties in the medical corps were enormous. The French military attaché reports that 4 per centum of the total killed and wounded among the Chinese officers were doctors. Notwithstanding the risk, there is no fear that medical officers will shrink from its encounter. Was ever Victoria Cross more worthily bestowed than upon Surgeon Captain Whitechurch, who, when the commanding officer was badly wounded during a sortie in the Chital campaign, a mile and a half from the fort and surrounded by the enemy, proceeded to his rescue and placing him on his shoulders, fought his way back, step by step, every now and then letting him down to head his men, constantly diminishing in numbers, in a charge to drive off the assailants, and whose first action when he reached the fort, though wounded himself, was to dress the wounds of his comrades! "Yet," said Dr. Da Costa, "this is only one more illustration of the gallantry and sense of duty so common among military surgeons. We have long looked upon them, and every day proves how truly, as uniting two professions—as possessing the courage and sense of nerve of the soldier, with the exalted devotion to duty and the high traditions of the doctor."

The first Vice-President, Medical Director Albert L. Gihon, U. S. Navy, having taken the chair, the President read his annual address, which will be published later in full. General Read referred to "the extensive and ever-extending field of medicine and the intricate and complex problems continually pressing for solution, in conjunction with the increasing individual responsibility of applying the resources at command that, years ago, disposed members of the medical profession to seek each other's counsel and form groups or clubs for the comparison of views and mutual improvement. The great advantages accruing from these comminglings prompted more extended social gatherings, until at the present time a large portion of the more progressive members in every civilized community are participating in local, municipal, national and international medical organizations. In the more frequent and familiar comparison of views and cases on all professional subjects in the local societies, closer habits of observation and a wider range of thought are induced, and bigotry and narrow prejudice give way to generous rivalry and personal friendships. In the larger gatherings, the formal preparation of papers and reports impels their authors to a wider range of study and greater mental discipline, while the collision with other minds in discussion develops all the aspects of the subject and enlarges the scope of mental vision by starting new trains of thought and begetting a broader and stronger mental grasp with purer and nobler aims in life." President Read then reviewed the great advances in professional knowledge in recent times, and appropriately dwelt upon its latest development in the Roentgen rays, stating the fact that "in the year 1890 Mr. Jennings, of Philadelphia, had associated himself with Dr. Goodspeed in experiments on spark photography. One evening, the 22d of February, 1890, at the close of work, with the table still littered by plate holders and apparatus, Dr. Goodspeed brought out the Crookes tubes for Mr. Jennings' amusement. Next day that gentleman wrote that he had had a curious failure among his plates—a negative spotted by two disks, but since no one could account for the phenomenon, comparatively uninteresting as it was, the plate was thrown aside and forgotten. Six years later, after the discovery of the Roentgen rays, it was recalled to mind and recovered. A duplicate was prepared under precisely the same circumstances. It was in a lecture on the evening of University Day that Dr. Goodspeed told the story and concluded thus: 'We can claim no merit for the discovery—for no discovery was made. All we ask is that you remember, gentlemen, that six years ago, day for day, the first picture in the world by cathode ray was taken in the physical laboratory of the University of Pennsylvania.' Such is the story of the development of a process entirely simple and of such sequence as to be almost obvious. Yet if its very simplicity had not concealed it, the story would have been cut short years ago, and America instead of Germany would have held the palm."

At the conclusion of the President's address, the Association adjourned until 3 P.M.

SECOND SESSION, TUESDAY, MAY 12.

VICE-PRESIDENT ALBERT L. GIHON, U. S. Navy, called the Association to order at 3 o'clock, in the assembly-room at the Hotel Walton, and the scientific program was at once begun.

The following, in the absence of the authors, were read by title, viz.:

"The Emergency Ration," by Capt. C. E. Woodruff, Assistant Surgeon, U. S. A.; "Experiments with Emergency Rations," by Capt. L. A. LaGarde, Assistant Surgeon, U. S. A.; "Tetanus Resulting from Powder Burns," by Capt. L. A. LaGarde, Assistant Surgeon, U. S. A.; "The Effects of Cannon Firing and Explosion on the Ear," by Dr. Samuel Sexton, New York city, after which, Col. C. H. Alden, Asst. Surgeon-General, U. S. A., read a paper entitled "Instruction of the Hospital Corps, U. S. Army," followed by a paper on "The Hospital Corps," by Major D. A. Kuyk, of the Virginia N. G., and this by one on "The Annual Encampment, and What it Teaches the Surgeon of the National Guard," by Capt. J. J. Erwin, Assistant Surgeon, O. N. G.

VICE-PRESIDENT GIHON then called upon the President, Surgeon-General Read, Pa. N. G., to open discussion on the several papers read, which he did by declaring that Col. Alden's paper had impressed him with a feeling of humiliation, mortification and annoyance, having always congratulated himself that Pennsylvania had the best hospital corps in the United States, his own experience of two wars entitling him to know something about it, and Asst. Surgeon-General Greenleaf, U. S. A., having commended it in an official report.

MAJOR W. H. EGLE, Service Brigade Surgeon of the Pa. N. G., and Major Weaver, of the First Brigade of Pa. N. G., described the organization of the Hospital Corps of that State,

and Lieut.-Col. Chas. F. Myers, Medical Director of the N. J. N. G., that of New Jersey, which he considers a perfect success. It is an independent body composed of sixty men, commanded by a captain who is a medical officer and a lieutenant who is not.

MAJOR FRANK T. LINCOLN, of Savannah, Ga., stated that he was extremely surprised to hear Col. Alden's eulogy of the Hospital Corps of the State of Georgia, because he knew there was no such thing in existence. He stated that the Medical Department of the Ga. N. G. was thoroughly well organized, the officers qualified and efficient, being compelled to pass a rigid examination before any one can obtain a commission, but this is not the case with the hospital sergeants and litter-bearers. Owing to the difficulty of inducing good men to enlist for this duty, he had come to the conclusion that the solution of the difficulty will probably be found in the enlistment of intelligent negroes for hospital duty. They make excellent nurses and while there is some reluctance to command them, he thought this was passing away and he was satisfied that in this way a Hospital Corps could be obtained, which could not be excelled anywhere in the United States or in the regular army.

SURGEON-GENERAL H. G. BYERS of the Wisconsin N. G., spoke of the difficulty he had in getting what was wanted, notwithstanding the utmost importance of having an intelligent and reliable hospital corps in every National Guard organization. It has not been found possible as yet to divorce them from the politicians. The line officers are generally prompt to render aid in case of emergency.

The Vice-President stated that inasmuch as the Association had heard from Col. Alden, it seemed but fitting that Captain Myles Standish should have something to say.

CAPTAIN MYLES STANDISH, Assistant-Surgeon M. V. M., stated that the State of Massachusetts mustered in its first man in the Ambulance Corps and enlisted under the statutes of the State in January 1885, which was two years previous to the Army and five or six years previous to New Jersey. The Ambulance Corps is a separate organization, of the same size as a company of infantry and has a captain and first and second lieutenants, all medical officers. The company has fifty-eight members, seven sergeants and ten corporals. There is no talk about hospital steward. They have an armory precisely like the infantry, are paid by the State, are furnished implements and have a drill every week in the year. They come willingly to enlist. The Adjutant-General has said that there is not an organization in the State which does so much to bring credit and appropriations to the National Guard as the Ambulance Corps.

MAJOR F. J. WOODS, of the New York N. G., spoke of the efficiency of the Hospital Corps of that State, which had recently been organized upon a separate basis.

COL. ALDEN closed the discussion and the Association adjourned its session, to reassemble at 10 o'clock the following morning at the University of Pennsylvania.

THIRD SESSION, WEDNESDAY, MAY 13.

The Association was called to order at 10:20 A.M., by President Read in Houston Hall, the use and privileges of which had been tendered by the House Committee at the request of the Faculty. The Vice-Provost of the University explained that this is a unique institution, being in fact a students' Club, with all the appointments of a well organized club and under the exclusive management of the students themselves. Its average attendance during the study season is a thousand members a day.

The session opened with the presentation of reports of the several Standing and Special Committees. The most interesting of these was the report of the committee on the "official Recognition of the Badge of the Association." Major Hoff, U. S. A., the chairman, stated that twenty-eight States had officially recognized the badge, but that similar action in the Army and Navy would require special legislation by Congress.

SURGEON-GENERAL BYERS of Wisconsin N. G., referred to the possibility of the badge falling into the hands of those not entitled to wear it—but Major Hoff said it was probable the Association would be able to prevent this abuse in the course of time, as had been accomplished in the cases of the Order of the Cincinnati, Military Order of the Loyal Legion of the United States, Officers of the War of 1812, etc.

The scientific program was then begun.

LIEUTENANT-COLONEL A. A. WOODHULL, Deputy Surgeon General United States Army, not being present his paper on "The Better Type of Medical Officers" was read by title.

SURGEON-GENERAL NICHOLAS SENN of Illinois National Guard, exhibited a new bullet forceps devised by himself for the extraction of the jacketed bullet, for which the old forceps is

absolutely useless, its sphere of future usefulness being, he feared, limited to the gynecologist. The new instrument is somewhat the shape of a bullet, so as to be used both as a probe and for grasping and extracting the jacketed bullet. When the bullet is located it is grasped by the two blades of the instrument, the tip of which has a very sharp point that it may follow the fine hole of the jacketed bullet. It is equally applicable for the location and extraction of the leaden bullet.

LIEUTENANT H. L. CHASE, Assistant Surgeon Massachusetts V. M., then read a very interesting and elaborate paper upon "Baths, Bathing and Swimming for Soldiers." It was a matter of regret that a companion paper on "The Physiology of Bathing and Swimming," by Lieutenant Henry G. Beyer, Surgeon U. S. Navy, was not received in time to be read in connection with the paper of Lieutenant Chase, which it was intended to supplement.

SURGEON-GENERAL FORSTER, Mass. V. M., commending the paper, explained that Massachusetts has three camp grounds with bathing and swimming facilities. Captain Jarrett, Assistant Surgeon N. Y. N. G., said that the camp ground at Peekskill, N. Y., was well supplied with bathing facilities, there being about two hundred baths. After each drill men rush for the baths, and most of the men bathe every day. In his own armory there is a French tiled swimming bath, twenty-five by fifty feet, with eight shower baths, and on the officer's floor private baths, needle baths, etc. Major Egle, of the Pa. N. G., said at the regular encampment at Mt. Gretna, there is an artificial lake of three acres of pure spring water which affords admirable opportunities for bathing, making it, in his opinion, the ideal camp ground of the United States.

The paper entitled "A General Consideration of Athletics; their Value in the Training of Soldiers," by First Lieut. William Allen Brooks, Jr., Assistant Surgeon Mass. V. M., was read by title.

A recess was then taken to allow the members to attend the clinic of Prof. J. William White in the surgical amphitheatre of the University Hospital and witness a demonstration of the diagnostic uses of Roentgen's rays.

The afternoon session convened at 2:30 p.m., in Houston Hall, and opened with the paper by Lieut. Thomas C. Craig, P. A. Surgeon U. S. Navy on "The Vitality of the Cholera Spirillum in its Relation to Certain Acids."

DR. EZRA H. WILSON, of Brooklyn, the Director of the Hoagland Laboratory, vouched for the accuracy of the experiments which he had witnessed. He stated that the destructive power of sunlight upon germs had been well established. The experiments conclusively established that the cholera spirillum could not survive exposure to direct sunlight more than four hours.

MAJ. CHARLES C. FOSTER, Mass. V. M., then read a paper entitled "Notes by a Medical Officer in the East." "Is There a Necessity for Differences Between the Standards of Physical Efficiency in the Regular Army and the National Guards?" by Lieut. Col. Charles R. Greenleaf, Deputy Surgeon-General, U. S. A., was read by title, as Major John Van Rensselaer Hoff, U. S. A., requested might be done with his own paper, entitled "What is the Most Practicable Plan of Sanitary Organization for the United States Army?"

MAJOR HENRY, U. S. A., the acting Secretary, read a telegram received from Brig.-Gen. J. D. Griffith, Surgeon-General (retired) Mo. N. G., to the effect that the experiments on which his paper on "The Effects of the New Gun in Field Service," was based were not completed, and asking that it might be deferred until the next annual meeting.

"Notes and Comments on the French Field Sanitary Service, and What We may Learn from It," was read by Maj. Valery Havard, Surgeon, U. S. A. "Modern Methods of Sewage Disposal as Applicable to Military Posts," by Maj. A. C. Girard, Surgeon, U. S. A., and "The Illustrated Travois," by Maj. W. C. Shannon, Surgeon, U. S. A., were read by title. "Some Thoughts on Wheeled Vehicles for the Transport of Wounded" was read by Maj. George W. Adair, Surgeon, U. S. A., and "What Standard of Visual Acuity Should Be Required of the Enlisted Men of Our Military Service?" by Capt. J. M. Banister, Assistant Surgeon, U. S. A., was read by title. Com. John C. Wise, Medical Inspector U. S. Navy, then read the paper by Lieut. Charles U. Gravatt, Surgeon U. S. Navy, on "Methods of Caring for Wounded in Field and Hospital of the Chinese and Japanese Armies." At the suggestion of Colonel Alden, U. S. A., the paper entitled "Synopsis of a Report on the Medico-Military Arrangements of the Japanese Army in the Field, 1891 and 1895," made to the Director-General, British Army Medical Department by Sur. Col. W. Taylor, Army Medical Staff, and presented by Col. Dallas Bache, Assistant Surgeon-General, U. S. A., was read by title.

MAJOR L. C. CARR, Surgeon Ohio N. G., called the attention of the Association to a litter which Maj. W. F. de Neidman, Surgeon Kan. N. G., desired to exhibit to the Association, a description of which was read by Lieut. H. A. Arnold, Pa. N. G. On motion of Major Hoff, U. S. A., the thanks of the Association were tendered to Major de Neidman for his courtesy in presenting his litter.

In response to the call of President Read, the delegations from the several States and Services represented named the following members of the Committee on Nominations:

California, Major W. D. McCarthy, of San Francisco.
Connecticut, Lieut.-Colonel L. B. Aling, of Norwich.
District of Columbia, Major G. B. Henderson, of Washington.
Georgia, Major F. T. Lincoln, of Savannah.
Illinois, Major Sullivan, of Chicago.
Iowa, Brig.-Gen. J. T. Priestley, of Des Moines.
Maine, Brig.-Gen. F. C. Thayer, of Waterville.
Massachusetts, Captain M. Standish, of Boston.
Michigan, Lieut.-Col. C. M. Woodward, of Tecumseh.
Minnesota, Brig.-Gen. J. F. Fulton, of St. Paul.
New Hampshire, Brig.-Gen. George Cook, of Concord.
New Jersey, Lieut.-Col. C. F. W. Myers, of Paterson.
New York, Capt. A. R. Jarrett, of Brooklyn.
Ohio, Capt. J. J. Erwin, of Cleveland.
Pennsylvania, Major J. K. Weaver, of Norristown.
Rhode Island, Lieut.-Col. C. H. French, of Pawtucket.
Virginia, Major D. A. Kuyk, of Richmond.
Wisconsin, Major T. W. Evans, of Madison.
U. S. Army, Col. C. H. Alden, of Washington.
U. S. Navy, Medical Inspector, J. C. Wise, of Washington.

FIFTH SESSION, THURSDAY, MAY 14.

The Association was called to order by President Read at 9:15 A.M. in the Union League Building.

Reports of Committees were deferred and the scientific program taken up. "Problems in Medical Administration, with Solutions; accompanied by suggestions as to the Application of this Method to the Instruction of the Medical Officers of the National Guard," was presented by Colonel Dallas Bache, Assistant Surgeon-General, U. S. A. "The Epidemiological Features of the Late Epidemics of Plague in China and Cholera in Japan," by Lieut. W. F. Arnold, P. A. Surgeon U. S. Navy. "Recent Advance in Anthropology Applied to the Physical Examination of Recruits," by Major P. F. Harvey, Surgeon U. S. A. "Outlines of the Sanitary Organization of the Army of Denmark," by Major John Van Rensselaer, Surgeon, U. S. A., were read by title. Commander J. C. Wise, Medical Inspector U. S. Navy read a paper on "Cooperation in Public Sanitation," and Major Paul R. Brown, Surgeon U. S. Army, a paper on "Modern Methods of Anthropometric Identification, so far as the U. S. Soldier is Concerned," advocating the Bertillon system, and eliciting considerable discussion among the officers of the Army as to the relative merits of the French system and that in vogue in the U. S. Army. Col. Alden described the latter in detail and claimed that the modifications devised by Col. Greenleaf and Major Smart, U. S. A., were all that were necessary. Since its operation was begun in July, 1891, "repeaters" have practically abandoned their game. About thirty-six thousand cards have been filed away—among them 4,000 cards of deserters and dishonorably discharged men.

MAJOR HARVEY, U. S. A., stated that while identification in the regular Army was based largely on accidental marks, the system of Bertillon deals more particularly with the congenital formation of the individual, and as no two men can possibly be precisely alike in the length of their bones and the configuration of their features, the system proposed by the French scientist, while more elaborate and difficult of execution, is an advance upon the present practice. He said that the paper, which he had read by title this morning, was in a measure supplementary to this system, looking to the prevention of enlistment of undesirable men by a study and interpretation of the marks of degeneracy indicating moral defects and criminal tendencies in the individual.

CAPTAIN MYLES STANDISH, Mass. V. M., thought that as the French system was associated with criminals, it would be difficult or impossible to adopt it in this country.

CAPTAIN JARRETT, N. Y. N. G., was also of opinion that in his State men would feel it an indignity to be thus measured and inspected.

MAJOR HOFF, U. S. A., inquired of Col. Alden if there had been any congestion of cards in the office of the Surgeon-General, and of Major Brown, whether the French system requires more or less time than the Army method.

To the first question Col. Alden replied that the cards were overhauled and as men outgrew the age of enlistment were

eliminated, and to the second, Major Brown claimed that he can examine a man thoroughly and make all the classifications and measurements in ten minutes, which he could not do by the other method.

MAJOR VALERY HAVARD, U. S. A., stated that his own experience with the Army system had not been satisfactory. Some men were referred to him for identification and he found it impossible to make sure that these men were originally enlisted and after awhile they volunteered to acknowledge that they had not been. Had they insisted on the contrary it would have been impossible for a jury to have convicted them on these cards. So far as the indignity and humiliation are concerned, he thought when a man is stripped and his marks and defects noted, he has been subjected to as much indignity as he can be. Therefore he preferred the most scientific system based on anatomic data.

MAJOR FOSTER, M. V. M., spoke of the necessity of physical examinations to preserve the efficiency of the regiments of the N. G.

MAJOR WEAVER, Pa. N. G., stated that Pennsylvania examines all recruits for her National Guard according to the Army plan.

COLONEL HENRY, N. Y. N. G., said that in face of the persistent opposition of the line at the outset they had succeeded in enforcing a modified system of examination in New York, and that commanding officers have now become convinced of the necessity for such examination and encourage the medical officers in insisting upon it.

MAJOR VALERY HAVARD, U. S. A., exhibited a litter on behalf of Frederick Remington, which belongs to the bicycle wheel class.

MAJOR D. A. APPEL, U. S. A., exhibited his improved litter-sling.

The Nominating Committee through its Chairman, General Cook, N. H. N. G., reported as officers for the ensuing year:

For President: Commodore Albert L. Gihon, Medical Director U. S. Navy (retired).

For First Vice President: Brigadier General Edward J. Forster (since deceased), Surgeon General Mass. V. M.

For Second Vice-President: Major John Van Rensselle Hoff, Surgeon U. S. Army.

For Secretary: Major Herman Burgin, Surgeon Pa. N. G.

For Treasurer: Captain James J. Erwin, Surgeon Ohio N. G.

For Editor: Lieutenant W. Lincoln Chase, Assistant Surgeon M. V. M.

Columbus, Ohio, as the place of meeting in 1897.

LIEUTENANT CHASE having declined the editorship on the score of pressing occupation, Major Charles C. Foster, Surgeon M. V. M., was elected to the office of Editor.

A vote of thanks was tendered Major J. Wilks O'Neill, Pa. N. G., Chairman and his associates on the Local Committee of Arrangements for the beautiful flag which they had had made and presented to the Association, and which on motion of General Cook, N. H. N. G., was adopted as the official flag of the Association, to be displayed at each annual place of meeting. The flag is of white ground bordered with green, displaying in its center the distinctive device of the Association—the Geneva Cross, American Shield and the motto, "*Omnia pro Patria Caritate*." The unfurling of the flag over the headquarters of the Association at the Hotel Walton on Tuesday morning was made the occasion of a pretty ceremonial, a military band of the Pa. N. G. playing the American, followed by the Swiss national airs; as the stops were broken and the flag unfurled the members greeted it with hearty cheers, and it continued to float from the tower of the hotel during the entire meeting.

At noon a recess was taken to attend a clinic at Jefferson Medical College to witness operations by Surgeon General Sean and Prof. W. W. Keen.

SIXTH SESSION, THURSDAY, MAY 14.

The final session was called to order by President Read at 3:30 P. M., at the Hall of the Union League, and the reading of papers resumed. "The Use of Kola for Military Purposes by Practical Experience," by Col. G. H. Penrose, Surgeon-General Utah N. G. "A Plea for Earlier and More Permanent Treatment of the Wounded on or near the Battlefield," by Col. W. H. Forwood, Deputy Surgeon-General, U. S. A., and "The Medical and Surgical Equipment of a XVth Century Military Expedition," by Lieut. H. R. Stiles, Assistant Surgeon, U. S. A., were read by title. "The Treatment of Sick and Injured Civilians at the Summer Camps," by Lieut. H. A. Arnold, Assistant Surgeon Pa. N. G., and "Methods of Instruction in First Aid," by Capt. J. E. Pilcher, Assistant Surgeon, U. S. A., were read by their authors. "A New Apparatus for Maintaining Apposition of Bones After Resection, or in Frac-

tures with a Tendency to Displacement," by Col. C. Parkhill, Surgeon-General, Colo. N. G., and "The Medical Department of the National Guard of Pa.," by Maj. Edward Martin, Surgeon Third Regiment Pa. N. G., were read by title. A paper on "Asbestos Surgical Field Dressings," was read by Maj. D. M. Appel, Surgeon, U. S. A., who exhibited a complete outfit of such dressings, and the lengthy and interesting program was concluded by the exhibition and description of a new centrifuge by First Lieut. Robert P. Robins, Assistant Surgeon Pa. N. G.

The President-elect then announced his committee appointments for the ensuing year, and the Association by resolution extended its heartfelt thanks to its retiring President, Surgeon-General Read, for his prompt and faithful attendance, his impartial rulings and his unflinching courtesy as presiding officer. Three times three cheers and a tiger were given for President Read, who replied happily in acknowledgement, and on motion, declared the meeting adjourned *sine die*, thus terminating the most successful meeting of the Association since its organization. Its roll of membership comprises 386 active members, 27 associates, 25 honorary and 22 foreign corresponding members. The active members represent the National Services and the National Guard and Volunteer Militia of forty-five States and territories, Arkansas, North Dakota, Oklahoma and South Carolina alone not being represented.

The lamentable death of the newly elected first Vice-President, Brigadier-General Edward J. Forster, the Surgeon-General of the State of Massachusetts within a few hours after the adjournment, was the only unfortunate occurrence connected with this meeting. Sitting on the salon deck of the Sound steamer for Fall River, Mass., while at her dock in New York, awaiting her departure, and conversing with his friend and fellow traveler, Col. Robert A. Blood, Surgeon M. V. M., he suddenly fell forward from his chair and quickly died from apoplexy. General Forster was one of the most zealous and energetic members of the Association, and his loss will be felt especially in the Executive Committee, where his opinions and counsels were greatly valued. The preceding report shows how often he was heard in the discussions at the general sessions.

SELECTIONS.

Spontaneous Healing of Laryngeal Ulceration in Pulmonary Tuberculosis.—According to the *British Medical Journal*, Dr. K. Clar has reported in the *Wiener klinische Wochenschrift* the case of a man who in 1884, at the age of 31, came to Gleichenberg with cavernous signs at the right pulmonary apex and catarrhal signs at the left apex. There was ulceration of the posterior wall of the larynx and of both vocal cords. At first iodoform insufflations were made use of, but owing to the obvious tendency toward spontaneous healing this was discontinued, and no local manipulations were thought necessary. Inhalation of the finely pulverized muriated alkaline water of Gleichenberg was employed, with much milk in the diet and mild hydrotherapeutic treatment. In August, 1886, on examination of the larynx it was found that cicatrization of the ulcers had taken place, but their position could still be easily made out. The ulceration on the posterior wall of the larynx had evidently been what Stork terms a "fissure" and it would be wrong to call it a tubercular ulcer. Infection of the ulcer with bacilli from the sputum might easily have taken place; if, however, it did take place it must have healed up again. In the following years the vocal cords gradually resumed their normal pale appearance, and in September, 1895, one could hardly distinguish anything abnormal in the larynx. The physical signs in the lungs have remained much the same, but during last year there was fewer and temporary increase in the catarrhal signs on the left side, which, however, improved during residence at the health resort.

Congenital Hypertrophy of the Liver.—An article on this subject was read at the Medical Congress at Rome last October, by the author of "Morphology of the Human Body," Professor De Giovanni. It was a plea for the value and importance of clinical observations and experience, when conducted on morphologic principles. He described several apparently most diverse

cases of ascites, cirrhosis of the liver, etc., which by his morphologic method he diagnosed as congenital hypertrophy of the liver and its consequent predisposition to morbid conditions. Treatment was in most cases simply a mild laxative and diuretic, with a milk diet and local treatment of complications. In one case fifteen liters of fluid were removed from the abdomen which had been so distended that it would not contract, and a large ellipse-shaped piece had to be taken out of it in front to reduce the size and restore circulation. Recoveries were permanent, as patients persisted in careful diet which he warned them was indispensable in the case of their predisposition. *Wiener klin. Rundschau*, March 8 and 15.

Ulcerative Endocarditis due to the Gonococcus.—Drs. Thayer and Blumer report in the *Archives de Méd. Exper. et d'Anal. Path.*, a case of ulcerative endocarditis associated with the gonococcus. The case was that of a woman who presented the clinical signs of acute endocarditis, but no evidence of gonorrhea. Gonococci were cultivated from the blood during life by mixing about two cubic centimeters of the blood from the median vein with melted agar agar. The blood was withdrawn by means of a sterilized hypodermic syringe. The mixture of blood and agar-agar forms an excellent culture medium for the gonococcus as has been shown by Wertheim. There seems no reason to doubt the identity of the organism thus isolated, for it showed those characteristics of morphology, culture, and reaction toward Gram's method of staining which serve to distinguish the gonococcus from other pyogenic cocci. The autopsy showed an ulcerative endocarditis and in the heart lesions large numbers of cocci were found, which, by their form and lack of staining by Gram's method, as well as their inability to grow on the ordinary culture media, must be accepted as gonococci. It is to be regretted, however, that the authors did not isolate the organism on suitable culture media at the autopsy and thus make complete the demonstration of its identity. The infection-atrrium in this case seems to have been the genital tract, for at the autopsy gonococci were found in the uterine cavity and in the vagina, but without any marked signs of inflammation of these parts.

Renal Changes in Diphtheria. The *British Medical Journal* reports that Dr. Reiche says that in eighty-five fatal cases of diphtheria before the serum treatment he always found more or less marked renal changes: seventy-five of the cases occurred in children under 10 years of age. There were no characteristic naked eye appearances. Microscopic changes existed chiefly in the parenchyma, in the interstitial tissue and in the glomeruli. The former were present in but slight degree. There was cloudy swelling, and sometimes fatty changes in the renal cells. A crumbling away of the central part of the cells with consequent filling of the tubules with debris was noted. Only the remains of the cells could be seen in some places. In a very small number of cases a coagulation necrosis had led to the destruction of the epithelium in places, but necrosis of single cells was much more frequent. In forty-four cases there was inflammatory proliferation in the interstitial tissue, and this was marked in seven cases. In some of the cases this was perivascular in distribution. The renal cortex was more affected than the medulla. The glomeruli were always involved. There was exudation into the capsular space, and alterations in the capillary loop as well as in the capsular epithelium. The exudation contained cellular remains, and occasionally red blood cells. Sometimes portions of the capillary tuft were stripped of epithelium, and the cells of the capsule were occasionally swollen. Casts were seen in two-thirds of the cases, mostly hyalin, rarely granular, with cellular debris: they were found chiefly in the straight tubes, etc. In three cases there were interstitial hemorrhages. The vascular distension was variable. Thus, along with degenerative lesions, there were others of an inflammatory and productive

character. These lesions are produced by the diphtheria toxins. Slight changes were also found in the liver, and sometimes in the pancreas. The author observes that the changes in all three organs were more common in cases of asphyxia.

Differential Diagnosis of Ileus.—Naunyn has an able study of this subject in the new periodical with the picturesque title: "*Communications from the Borderland Between Medicine and Surgery*" (*Mittheilungen aus den Grenzgebieten der Med. und Chir.*), page 38. In regard to operating, he reviews 288 cases, and states that the best results are secured if the operation is performed in one to two days after the commencement of the ileus, as the percentage of recoveries falls from 70 to 34 per cent. if the operation is delayed to the third day. Cases of ileus with hernia afford exceptionally favorable results. Of course he does not refer to strangulated hernia, but to ileus resulting from stagnation, adhesences and loops in the neighborhood of the hernial sac. The reason for this surprising fact is that the surgeon knows then exactly where to operate, which emphasizes once more the great value of correct local diagnosis. In differentiating ileus from simple obstruction, he notes that in the latter, gas can pass, and tympanites is absent. Vomiting and severe general distress are absent in hysterical tympanites also. Visible peristaltic action decides in favor of ileus, especially in a volvulus. It is very difficult to decide between ileus and acute primary peritonitis. Visible or palpable peristalsis favors the former, while the latter is suggested by commencing fever, continual vomiting and discovery of some etiologic points in the stomach complications, worm processes, etc. Indican in the urine has no diagnostic value. Naunyn describes in detail the important distinctions between acute and chronic ileus, and shows that peristaltic action, which is almost the only means of differentiating them, can also occur in a volvulus in acute occlusion. The exact location of the occlusion can only be determined when it is in the duodenum or upper jejunum, or in the descending colon. It is important to decide whether there is strangulation with the ileus, as an operation becomes imperative in that case; the diagnosis is founded on the rapid septic collapse, and a solid distended volvulus. A free serous hemorrhagic discharge seems to be a frequent accompaniment.—*Centralblatt für Chirurgie*, May 2.

Influence of Static Electricity on the Tension and Course of the Pulse.—Dignat has been making a careful study of the pulse of sixty-two patients before and after the electric bath, and notes a marked difference: 1, noticeable diminution of the amplitude of the pulsations after the bath; 2, greater regularity of pulsations after than before; 3, greater frequency of pulsations after franklinization; 4, decrease and sometimes total disappearance of diastolic and polycrotism. He was very careful to investigate the pulse always on the same side, with the patient always in the same position, the arm resting relaxed on a support, with a cylindric roll (always the same), held lightly in the fingers. He also verified before he began, each time, with the dynamometer of his sphygmograph (Dudgeon's) the exact pressure of the spring on the artery, and if there was any change from last time registered, he altered the spring until it showed the same figure as before.—*Journal de Méd. de Paris*, January 19.

Etiology of Leprosy.—According to the *Press and Circular*, Professor Kaposi has recently delivered some exceptionally interesting clinical lectures on leprosy, its varied manifestations and the diverse interpretations that have been placed upon its pathologic developments. For a long time the disease was conclusively shown to be hereditary, which was satisfactorily admitted from the histories obtained of families residing in districts where the genealogy of different stocks could be traced in the registers of different parishes. Danielsen and Boeck have spent much time in endeavoring to disprove or establish this doctrine. The latter followed healthy children, who had been born of leprosy parents, to America, who after a time had settled on that continent, and became afflicted with the disease. There may be a certain amount of error in connection with this question of heredity, as many of the families had intermarried and resided in the same neighborhood for generations, thus fixing the transmission temporarily, as we find it disappearing in many districts without any apparent cause, which would not occur if heredity was the base of transmission.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the ASSOCIATION living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, MAY 30, 1896.

MNEMONICS OF ANATOMY.

To the student commencing the study of anatomy the number and variety of details he is required to memorize is generally appalling. Not infrequently he abandons the effort in despair; sometimes he contrives to retain a certain proportion of these details by the use of more or less appropriate "catches" or mnemonics. This use of *memoria technica* dates back to the early classic writers and nearly every one, even at the present day, has occasion to use some form of them—at least that familiar one concerning the number of days in the months. But for anatomy few are in use in this country and the ones generally heard are that about "vexatious Timothy" and a suggestive one relating to the position of the bones in the carpus.

In the old country, on the contrary, and especially in France, every medical school has its series of "catches" and some of them are thought to be of sufficient importance to be introduced into the standard treatises on anatomy.

Something more than two centuries ago BIMET published a poetic osteology¹ which seems the first effort to apply the mnemonic method to the bones. The following is a specimen quatrain:

L'occipital ressemble au devant d'un navire;
Il paroît le plus grand et plus épais de tous,
Afin de résister plus fortement aux coups,
Qui sans cette épaisseur luy pourroit beaucoup nuire.

¹ Quatrains anatomiques des os et des muscles du corps humain, par Claude Bimet, 1664.

There are 339 of these quatrains in the osteology alone; that part relating to the muscles is much shorter. BIMET had been preceded in myology by QUARRE, who published his work,² a quarto volume, in 1638. Some years later than BIMET's work appeared another osteology in verse by ABEILLE.³ These verses are of irregular lengths and we find, from the one selected on the use of the trephine, that surgeons then as now were chary of applying this instrument over the sutures—as witness:

SUR LE TRÉPAN.

Si tu veux sur le crâne en vray praticien
Appliquer le trépan pour guérir les fractures
Prens d'abord le conseil d'un bon chirurgien,
Évite surtout les sutures.

Fais un bon pronostic et d'ailleurs ne crains rien.

Another work of this character was published in Italian.⁴ The latest attempt to combine poetry with osteology is by a French author, E. ARTANCE.⁵ This writer explains in his preface that he composed the work for his own use and that he offers the first part to his "condisciples," hoping it will be beneficial. "If it is received favorably," he says, "I will publish the other parts; if not, I will keep them for myself." Evidently the work was not received favorably, for only the first part was published, including the description of the bones, joints, teeth and organs of sense. The first few lines of the twelfth verse—on the sphenoid—will give an idea of the whole:

Cet os dont la figure est irrégulière
Ressemble en quelque sort à l'oiseau mammifère
Par dix ou douze points ossifiés d'abord
Il offre à d'autres os six faces, double bord;
Une face inférieure ou dite gutturale, etc.

CATTELL, in a recent article entitled "Some Anatomical Mnemonics,"⁶ points out the utility of the system and gives some of the "catches" usually employed, in addition to a few original ones. But the most important work on this subject which has yet appeared is that by WITKOWSKI,⁷ the inventor of the well-known iconoclastic manikins. This is in two volumes of 960 pages, with 955 cuts or illustrations, and covers the entire subject of anatomy, with some hundred pages devoted to physiology and the like. Some of the illustrations are quite ingenious, as, for instance, the one representing the *extensores radii* as two malefactors between a large and small gendarme (the long and short supinators). Others, including one on page 72 of Vol. II, are decidedly Gallic. It is characteristic of medical students that several of the "catches" that are in use in the French schools, especially that of Lyons, verge or actually trench on the domain of pornography.

More use might profitably be made of mnemonics

² Myographia heroico versu explicata, auctore Guillelmo Quarre.

in anatomy and their introduction into text-books would, undoubtedly, prove helpful to the student. Many teachers decry their use, but any one who instantly recalls the colors of the spectrum by repeating the familiar *vibgyor* will need no further argument to convince him of their usefulness.

A STUDY OF THE OPERATIVE TREATMENT FOR LOSS OF NERVE SUBSTANCE IN PERIPHERAL NERVES.

The far-reaching pathologic changes which result from loss of continuity in the peripheral nerves, and the relative frequency of such injuries, have for many years been the object of much study and research.

Clinical and experimental observations have long ago shown that the function of a severed nerve can be restored if the divided ends are brought into close apposition by means of a suture or otherwise, and that the outlook for a successful result is better the sooner after the injury approximation of the ends is secured. Return of function is possible even without careful suturing of the divided ends, as witness, for instance, the return of a neuralgia after resection of a nerve. The general rule remains, however, that severed nerves must be accurately sutured. Usually injuries to nerves are of such a nature that not much nerve substance is lost, the ends being readily united, but it occasionally happens that in lacerated wounds several inches of a nerve may be destroyed, that in the removal of tumors of nerves the resected ends may be far apart, that after extensive inflammation and suppuration following nerve injuries the stumps may become so imbedded in cicatricial tissue that it may be exceedingly difficult, if not impossible, to find the ends; in such cases resort to simple suture is out of the question, and a large number of methods have been suggested from time to time to obviate the difficulties connected with restoring the lost substance. Considerable experimental work dealing with these problems has been done, the most recent as well as thorough research in this direction being that of HUBER,¹ of Ann Arbor, who tried experimentally the various methods suggested for restoring lost nerve substance with a view to establishing their comparative value. HUBER's article is divided into three parts: 1, a review of the literature; 2, the author's experiments and physiologic observations; 3, the result of the microscopic examinations.

The various methods which have been employed in the treatment of nerve injuries with loss of nerve substance may be grouped under the following heads:

- Nerve stretching (*Schüller*).
- Implantation of a nerve segment removed from a recently amputated limb, or from a lower animal.
- Tubular sutures (*Vaulair*).
- Union of ends with catgut threads, or a bundle of catgut threads (suture à distance, *Assaky*).

e. Nerve flap from the central stump, or a flap from both central and peripheral stumps (autoplasie nerveuse à lambeaux, *Létiévant*).

f. Grafting of the central end of the peripheral stump of a divided nerve to an accompanying nerve trunk (greffé nerveuse, *Létiévant*).

g. Cross suturing the long central and peripheral stump in cases where two accompanying nerves are cut obliquely, and grafting the central short stump to central long one, and peripheral short stump to peripheral long one (*Létiévant, Tillmanns*).

h. Resecting the bone or bones in the extremity and suturing the nerve.

These various procedures have all been tried in practical surgery; in most cases the feasibility of the method was first demonstrated by experiments upon animals. A complete tabulation of the surgical cases in which a defect in a peripheral nerve was treated by operative means has not been made. HUBER collects twenty-three cases and the following table gives the general summary of the reported cases. It is almost unnecessary to add that it is an exceedingly difficult matter to give a correct summary of such complicated and often imperfectly observed or described phenomena as are dealt with in these cases.

TABLE GIVING SUMMARY OF REPORTED CASES.

Operation.	Nerve Operated Upon.	Operation.	No. of Cases Reported.	Successful.	Improved.	Failures.	No. Cases Observed 2 mos. or longer.	Observed less than 2 mos.	Incomplete Report as to Result.	Remarks.	Implanted segment necrosed once.	Report gives condition 16 days after operation.

It will be seen that the operation for nerve implan-

¹ Journal of Morphology, Vol. XI, No. 3, 1895.

tation has been performed fourteen times, eight times as a primary and six as a secondary operation. Of this number three are reported as successful, seven as improved and four as failures. In one of the cases at least, namely, ATKINSON'S, the report covers a period of but sixteen days after the operation, at which time sensation is said to have become fully reëstablished. HOWELL and HUBER show, however, that in man sensation does not return to the peripheral part of a divided nerve until three months after suturing. Hence there can be no doubt but that in ATKINSON'S case the sensory impulses were carried along one of the other cutaneous nerves distributed over the extremity. All experiments bearing on this problem show that the implanted portions always degenerate.

HUBER'S experiments were made on dogs. With but few exceptions the ulnar nerve was used. When implantation was made a segment was taken from the sciatic of a cat. The length of the piece excised varied from 4 to 8 cm. The details employed in experiments with other methods were simple and uncomplicated. In all cases asepsis and careful suturing were secured. The irritability of the nerves was examined by means of induction shocks from a DU BOIS REYMOND coil under such conditions that the results obtained admit of comparison. The final functional results obtained are shown in the following table:

Operation.	Number.	No. where 120 days or more intervened between operation and examination.	Cases observed 120 days or longer.			Failures.
			No. in which regeneration was complete.	No. in which regeneration extended to middle of forearm and to muscular branch of flexor carp. uln.	No. in which regeneration extended to just below peripheral wound.	
Nerve implantation. . . .	26	10	5	4	1
Bone tube implantation. . .	8	4	1 (sec. impl.)	2	1
Implantation of catgut threads. . .	7	3	1	1	1
Létiévant's flap operat'n	7	2	2
Létiévant's grafting. . .	1	1	1
Tillmans cross suturing and grafting. . .	1	1	1

A number of animals were sacrificed from time to time in order to study the changes that occurred in the nerves experimented upon. It was found that the best method for demonstrating the developing axis cylinder is to harden in MUELLER'S fluid and to stain with STROEBE'S anilin blue-safranin solutions. HUBER shows that after primary implantation of a nerve segment between the resected ends of a peripheral nerve, the entire peripheral stump and about three-quarters cm. of the central stump degenerates: the myelin and the axis cylinders of the implanted piece are absorbed within ten days after the operation. Regeneration begins in the central stump and proceeds centrifugally; it consists of a down-growth

of the axis cylinders of the nerve fibers of the central end through the implanted segment and the peripheral part of the resected nerve. It requires at least 136 days for the regenerating median nerves to reach the peripheral part of the trunk, and 149 days in case of the ulnar. The down-growing axis cylinders travel along and in the sheaths of the old and implanted nerves.

He further found that in the flap method, the nerve flap degenerates throughout its whole extent, that in the central stump were many degenerated fibers, due to the traumatism inflicted while making the flaps, and that the budding axis cylinders were largely lost in the connective tissue between the nerve ends.

Without going into further details it is evident that the results of HUBER'S experimental research are of great practical importance. The following conclusions are certainly warranted from his study of the literature of this subject as well as from his personal observations:

1. That it is possible to restore the functional activity in a nerve with loss of substance, if the ends are united with a segment taken from some other nerve trunk, with catgut threads or with a bone-drain or tubular suture.

2. Of all methods enumerated and tried the best results are to be obtained after the implantation of a nerve segment the two ends of which are sutured by several catgut sutures to the end of the resected nerve.

3. The regeneration of the peripheral end which always degenerates so that only the sheaths of SCHWANN are met with, is the result of an outgrowth of new axis cylinders from the central stump, the budding axis cylinders following the paths of least resistance through the substance interposed between the ends of the nerve, thus reaching the peripheral part of the nerve.

4. Since the fibers in an implanted nerve segment degenerate so that only the collapsed sheaths containing a small amount of nucleated protoplasm remain, and the catgut threads used in a suture à distance, and the bone tube employed in a tubular suture, are almost entirely absorbed before regeneration has occurred to any extent, it must be concluded that the implanted substances can serve only as a guide to the budding axis cylinders.

5. That the degenerated fibers of an implanted nerve offer more favorable mechanical condition for the down-growing axis cylinder than does the connective tissue replacing various other substances, is shown by the fact that the new nerve fibers have a much straighter course and more regular arrangement in the nerve implantation experiments than in the experiments with catgut and bone-drains.

6. The same results may be obtained with these methods whether used in primary or secondary oper-

ations. The return of function takes place more slowly in secondary operations.

7. Nerve-flap formation from central or peripheral stump is not recommendable, because: 1. the flap degenerates; 2. the union with the central end is not so favorable for the budding axis cylinders as in nerve implantation, and 3. the growing fibers seem to bud into the connective tissue and not into the reflected flap.

8. Regeneration through an engrafted connection between the peripheral part of a divided nerve and an accompanying uninjured trunk is not possible.

9. In the LÉTIÉVANT-TILLMANN'S operation (cross-suturing the long ends of two divided nerves and engrafting the short ends to the accompanying long stump) regeneration of but one of the peripheral segments of the two injured nerves can be hoped for; the other peripheral segment remains degenerated; as there is no reason why a regeneration of both the peripheral stumps may not be attained after the implantation of a nerve segment between the respective ends of the two injured nerves, preference should be given to the latter method.

MEDICO-LEGAL USES OF THE ROENTGEN RAYS.

The surgical application of the ROENTGEN rays is already an old story, at least as far as the surgery of the bones, more particularly in the extremities, is concerned. Their medico-legal utility is a later demonstration, though it might readily be inferred from any brief consideration of their effects. A young woman, an actress, broke her ankle while descending a stairway in an English theater. A suit for damages was instituted against the proprietor, on the claim that the accident was due to a defective step. This seems to have been proven or admitted as the defense was made that the injury was exaggerated. A ROENTGEN shadowgraph, presented before the jury, secured the plaintiff her case, the evidence being held to be incontestable.

It will be easily seen how the pictures obtained by these rays will figure hereafter in damage suits, but this is only one of their possible medico-legal uses. In the May issue of the *Annales d'Hygiène Publique et de Médecine Légale*, DR. T. BORDAS of the Faculty of Medicine of Paris gives illustrations of shadowgraphs of fetuses, which are especially illustrative as regards the development and arrangement of the bones, and he suggests that it may be possible to obtain facts as regards the condition of the lungs, etc., that will be of medico-legal value in certain cases. He also shows how these rays can be made useful in detecting the nature of suspicious packages, suspected infernal machines, without incurring the danger of opening them. Certain of the explosives used in these, the fulminate of mercury in particular, are quite opaque to these rays, and metal clockwork would naturally show in a shadowgraph. There is quite a

range for investigation as to the relative behavior of different chemicals under these rays, that may in the future come before the courts in one way or another, and still another possible value they may have will be in certain questions of identity. An old fracture that is of importance in settling this question, a bullet with a history lodged in the tissues, or some other possible known peculiarity may reveal itself in the ROENTGEN negatives. On the whole the possibilities of the medico-legal value of the discovery seem quite important, and as the unexpected is always what happens, they may make their appearance in unlooked for situations. The subject is at least a suggestive one.

THE PERMANENT LOCATION.

The members of the ASSOCIATION will receive in a few days a ballot and return envelope addressed to the JOURNAL office. In accordance with the rule of the ASSOCIATION passed at Atlanta, sealed ballots will be received from June 1, to July 31, 1896. Every member is requested to vote on this question, and to sign his name legibly to the ballot, with the name of the place and his post office. These ballots, after opening the envelopes and counting, will be preserved until the next meeting of the ASSOCIATION, but the result of the count will be announced in the issue of the JOURNAL next succeeding.

The Trustees have set apart \$3,000 to be placed at interest as the commencement of the building fund, and it is hoped that a much larger surplus may be set aside next year. Meanwhile before investment, it was necessary to take the wish of the ASSOCIATION as to a permanent place of publication. The proposed method is absolutely fair, and the JOURNAL itself will take no part in the matter, whether the vote shall result in the establishment of the permanent headquarters of the JOURNAL at the National Capital at Washington, or whether it shall remain in the metropolis of the West at Chicago or go elsewhere, is not a matter for concern or interference on the part of the present management of the JOURNAL. The management only hopes that members may vote solely with respect to the advancement of the interests of the ASSOCIATION, without regard to individuals or coteries. The recent growth of the ASSOCIATION in every State in the Union, and the rapid increase in the number of those who are active workers in the field of organization, gives every hope of a wise ballot, and cheerful acquiescence in the result.

CORRESPONDENCE.

The Second Pan-American Medical Congress.

A REPLY TO REFLECTIONS UPON THE MEXICANS AS PHYSICIANS
AND AS A RACE.

GALVESTON, TEXAS, May 16, 1896.

To the Editor: The approaching meeting at the City of Mexico of the second Pan-American Medical Congress, and the

appeal of our most efficient Secretary General, Dr. Charles A. L. Reed, to attend it, have aroused in me a variety of feelings impossible to describe at this moment.

Dr. Reed has stated: "The enthusiasm with which not only the medical profession, but the government of Mexico has taken hold of the proposed meeting, guarantees its success. The generous patronage which the Washington meeting enjoyed from our Mexican *confrères* places upon us a pleasant obligation to reciprocate."

Would that the whole medical fraternity of this country entertained sentiments similar to those expressed by Dr. Reed. But there are exceptions to be deplored, exceptions that tend to delay at least the unity of the profession on this continent, to judge from the attitude of some of the physicians of this country toward our southern *confrères*, and especially toward Mexicans. And sad to relate, the matter seems to be a question of national prejudices, a racial battle, as it were, this a stumbling block to true progress in all human affairs.

Although I have taken them for what they are worth in my humble estimation, and to a certain extent overlooked, pardoned them, I have not forgotten, nor perhaps will ever forget, the insults heaped upon my people by American physicians, and I deem this occasion an appropriate one to recall and resent these insults. In an article entitled "Clinical Notes on Typhus Fever of Northern Mexico," read before the Texas State Medical Association at the April (1894) meeting, and afterward published in the Transactions of the same, Dr. Clarence Warfield has this to say about the Mexicans:

"Morality (a thing unknown) is at its lowest ebb. When, from sickness, one of these people die, no matter how contagious may have been the disease, the neighbors crowd in to view the remains, even little half-naked children climbing in over the doorstep to satisfy their already growing morbid curiosity.

"A Mexican family may be ever so poor, but one or more dogs form a part of their belongings, which, when night comes, and the floor is strewn with forms of all ages and sexes, some covered and some uncovered, lie down also and fill up the intervening spaces. These people rarely undress, the same old clothing worn continuously and dirt hiding the original color of underclothing, uncleanness and germ-laden atmosphere, all tend to encourage sickness of every sort. *Incest is of frequent occurrence, many fathers having children by their daughters and all living together.*

"They are morbidly afraid of the 'aire' (air) and 'sol' (sun) as causative agents of disease, and water as an intensifier of the same when once established, every case of sickness being, from their standpoint attributable to either one or the other, and it is a foregone conclusion that water will not be used, except for drinking purposes, throughout the trouble. *As this belief is more or less encouraged by their physicians, no one can convince them to the contrary.*"¹

Dr. M. B. Ward published in the September (1894) number of the *Tri-State Medical Journal*, a paper entitled "Some Observations Relative to the Practice of Medicine and Surgery in the Republic of Mexico." The article contains many assertions unworthy of an impartial, dispassionate judge. Its tone is strictly non-ethical. Some of the remarks made in that document not only lack foundation, but are positively ungenerous, not to say defamatory, insulting to our brother physicians in Mexico. I will not quote from Dr. Ward's article for fear of making my communication too long.

Some one has wisely said that "an individual opinion is a very indefinite quantity, and may represent a great deal of knowledge or absolute ignorance." I will modify this sentence by saying that "an individual opinion is a very indefinite quantity, and may represent a great deal of knowledge, absolute ignorance or intentional malice." Granting that Dr. Warfield's effusions and Dr. Ward's assertions are based on the true state of medical practice in Mexico (and I can bring forth evidence to the contrary), the articles of these gentlemen do not show good judgment or discrimination on the part of the writers, nor do

they (the articles) as a whole reflect credit on the profession of the United States, even though the latter be not at all responsible for the single opinion of any one of its members.

Why such articles should have been allowed a reading before bodies of undoubtedly conscientious, grave medical men, as the members composing the Texas State Medical Association and the Tri-State Medical Society of Illinois, Missouri and Iowa respectively, and afterward publication. I do not understand. The whole matter, it seems to me, has been unfortunate.

Is conduct like that observed by Drs. Warfield and Ward, I wonder, a reason why many American physicians desire to have the Code of Ethics completely abolished? Because, to say the least, the papers prepared by Drs. Warfield and Ward seem to be, or pretend to cast, a slur on the Mexicans as a people and on the practice of the whole medical profession of a sister republic. If Drs. Warfield and Ward have a grudge against the Mexicans as a race, or against Mexican physicians for non-professional conduct, or what not, they should complain in the proper manner, and not simply make and publish charges when at a safe distance: for this procedure is not only non-ethical and impolitic but cowardly also. Apart from this, Dr. Warfield's onslaughts on the Mexicans as a race, and Dr. Ward's harsh criticism on the Mexican practice of medicine and surgery are unwarranted, uncalled for, even supposing to be true what they have dared to assert.

Without any mental reservation whatsoever, I regard the course taken by Drs. Warfield and Ward in this matter, not only thoughtless but eminently insulting to the profession of Mexico and to the people of that country in general. I do not care much for the opinion of the ignorant in affairs like the present, but it pains me to see educated professional gentlemen of this country, apparently without cause or provocation (which is still worse), assailing regular brother practitioners of medicine in other countries. It can hardly be believed that such conduct should be observed in a country where that magnificent document, a document pregnant with sound and healthy thought, the American Code of Medical Ethics, was created; in a country, indeed, that is noted for the general good sense and calm judgment of its citizens. Both Dr. Warfield and Dr. Ward are to be censured severely for their policy. My own satisfaction in the matter after protesting, as I do most emphatically against Drs. Warfield and Ward's attacks on my countrymen and professional brethren, is that their conduct will not be endorsed by the large majority of educated American physicians. I could with incontrovertible proofs correct each and every statement made by Drs. Warfield and Ward in their unfortunate articles, but I refrain from so doing, unwilling as I am to become involved in an unnecessary and probably angry dispute, or to impose on the patience of the reading public.

The noble efforts of the eminent American Physicians who first conceived the happy idea that tends to the unification of the profession on this continent, by the creation of the Pan-American Medical Congress, whose first meeting at the city of Washington in 1893 was crowned with brilliant success, will certainly not be materially aided by a policy such as that put in practice by Drs. Warfield and Ward. In his magnificent and eloquent discourse, the President of the Congress, Dr. William Pepper, made these concluding remarks: "Let us acquire here a closer touch with each other, a deeper faith in our profession and its noble destiny, and a stronger determination to labor in brotherly coöperation for the loftiest ideals of service to science and the race." Can this possibly be accomplished by maintaining now or in the future an attitude similar to that observed by Drs. Clarence Warfield and B. M. Ward.

The unbiased testimony of all scientific observers who have devoted special attention to the study of this subject, from

¹ Italics are mine.—D. C.

Humboldt to Brinton, shows that the Mexicans, unlike the various barbarous tribes of North American Indians, belong undoubtedly to a superior stock, and as evident proof of this there stands out in bold relief the immortal monuments which vividly interpret their remarkable advance in the arts, literature and science. But if, as the result of conquest, the energy of the Mexican race has been temporarily paralyzed as has similarly been the case with other nations of antiquity, like the Greeks and Romans for instance, my people, on account of physical, intellectual or moral characteristics, should not, can not be placed on the level with any of the truly inferior races. But what is to be expected from those blinded by prejudices, from those who are sadly wanting in logical reasoning? People there are so biased as to be carried to ridiculous extremes; people who, again, like unprincipled politicians of to-day, will say and do anything, no matter how degrading, for the sake of notoriety, or to gain certain selfish ends. The question is now being discussed in this State, for example, as to whether the Mexican is eligible or not to American citizenship! And why? On account of his origin. For it is claimed that he is neither a white man nor a negro! And what of it? But I will not enter into further consideration of so trivial a matter.

And as for the standing of medical science and the profession in Mexico, I will only say that serious observation by unbiased minds will certainly convey a better general impression of those matters than the thoughtless, ungenerous, not to say false, statements made by Drs. Warfield and Ward.

In conclusion, I sincerely trust that a large contingent of American physicians may attend the Congress at the City of Mexico on November next and, laying aside all prejudices of race or other prejudices (prejudices of any kind should not be entertained by scientific medical men), let those physicians see and study for themselves the characteristics of the Mexicans as an ethnologic element, and note whether they are not as capable of achievement in all the higher pursuits as our brethren north of the Rio Grande. I can assure the American physicians attending the Congress that, on their return, they will not imitate the conduct of Drs. Warfield and Ward (as they will have no true cause for so doing), or like a certain Mr. Lancaster of this State of Texas, say that the Mexican belongs to "a race more uncouth than the negro, less intelligent, less friendly, and more like a savage." Very truly yours,

DAVID CERNA, M.D., PH.D.

The Antivivisection Bill and the Senate.

The following informal and unofficial correspondence is self-explanatory:

CHICAGO, May 14, 1896.

The Hon. S. M. CULLOM, U. S. Senate.

Dear Mr. Senator:—The views of the AMERICAN MEDICAL ASSOCIATION, and of the profession generally, are so opposed to the bill now pending in the Senate for the restriction of vivisection that I venture to ask your powerful aid in defeating the measure, which I understand has in the Senate no less adroit an advocate than Senator Gallinger.

Nearly every notable advance in the science of physiology, *i. e.*, knowledge of the functions of the organs of the body, and the most valuable facts in connection with animal chemistry, and the effects of medicines, have been made and recorded in consequence of experimentation upon the lower animals, and we therefore look with alarm upon a bill which if it become a law, will relegate science in this country to a back corner. The people who make the greatest outcry are those who know least about the subject as a rule, and should their arguments be brought to a legitimate conclusion, we should close up the butcher shops and become vegetarians. I have great sympathy with our cattle, but at the same time I have an appetite for roast beef which vegetarian sentiment and a diet of turnips

and cabbage will not appease. When our antivivisectionists rise up and demand the passage of laws that they insist are for the protection of animals, let us insist that they prove that they are vegetarians and that by no weakness they sacrifice one of the lower animals to man's needs. Let us banish red snapper and pompano from the menu in the Senate restaurant, and as for the succulent canvas-back, the reed bird and the terrapin, let the *gourmet* die the death, unless he be willing to regale himself on beans and Boston brown bread instead. I can not conceive that the mighty fisherman from Maine or the gallant Nimrod from Missouri would consent to such a bill. The shade of Isaak Walton would rise in wrath to see any of his devoted followers forsake his paths at the first onslaught of a vegetarian enemy.

Can't you help defeat this imbecile offspring of the long-haired traveling physiologists, and let our laboratories teach the students in peace, unvexed by the nonsense of these dyspeptic sentimentalists?

Faithfully your friend, JOHN B. HAMILTON, M. D.

UNITED STATES SENATE.

WASHINGTON, D. C., May 18, 1896.

DR. JOHN B. HAMILTON, AMERICAN MEDICAL ASSOCIATION, Chicago, Ill.—Your favor of the 14th inst. is received and noted. I know so little about medical legislation, or the proper legislation in the interest of medical science and practice, that I have generally allowed such matters to go along without much interest upon my part. All I can say is, that I am in favor of whatever legislation may seem necessary and fair in the interest and progress of science and practice of medicine and the development of knowledge in the direction of physiology or a knowledge of the functions of the body. Just what the bill referred to by you means, I do not know, but I will try to give it attention.

I should be against any legislation that would interfere with the privilege of satisfying the appetite with a good roast beef, or mutton, or chicken, or duck, or terrapin, and if you can convince me that this proposed legislation is going to in any way abridge the rights of those who are fond of good things to eat, I am "agin" it. I am not so particular about red snapper as I am about canvas-back duck or terrapin. I could even spare the reed bird, but I shall insist upon all the other good things mentioned in your letter, and am opposed to any interference with their free use. While I am fond of Boston baked beans, and not particularly opposed to brown bread, yet I would not surrender a well prepared sirloin steak for either. I am not very familiar with the history and characteristics of Isaak Walton, yet I believe he was called an "angler" and his name has become immortal on account of his relation to his writings setting forth the delights of fishing, and charming those who have never become familiar with such recreation, by his works. I am one of those who have known very little about fishing—scarcely knowing how to put a worm on a fish hook—yet I have always had a fondness for shad in the spring and for white fish almost any time, and am, therefore, against any bill which would interfere with the freedom of those who are fond of fishing as a recreation—or of eating a good fish as a food.

So you may gather from what I have said that I am with you as against any legislation which will in any degree circumscribe the advancement of science or the enjoyments of eating meats or fish as a food.

Very truly yours, S. M. CULLOM.

Proper Title of a Medical Officer of the Army.

GROVELAND, MASS., May 4, 1896.

To the Editor: I notice in the JOURNAL of February 1 an article entitled "Some Remarks about Asepsis in Military Service," read, etc., by Lieut.-Col. —.

At first one would wonder what a military man might know about asepsis, and although there is little of professional instruction contained in the paper, I infer that this Lieut.-Col. for some reason or other ignores his professional title. This craze makes me tired, Doctor. Time was when the honorable title of doctor would be considered an honor for a prince. In point of fact, there is to-day no more honorable title, and no good reason why physicians who respect their profession should be willing to exchange it for a complimentary military title.

I send you a communication received recently from the Secretary of War. For the sake of the profession and to put a damper on bombast and militarism in the usually dignified and modest profession of medicine, you may deem best to publish all of this. Sincerely yours,

W. THORNTON PARKER, M.D.
GROVELAND, MASS., Jan. 26, 1896.

To the Honorable Secretary of War, Washington, D. C.

Sir:—I respectfully write for information concerning the commissions of medical officers in the United States Army.

In the U. S. Navy and in the Marine-Hospital Service, medical officers are known as surgeons, passed assistant surgeons, assistant surgeons, etc., and even in the armies of Europe, where the most radical system of militarism exists, under monarchical rule, medical officers are known as surgeons, assistant surgeons, etc. But in our republican form of government, where the rights of citizenship are asserted to be preëminent, our surgeons have of recent years placed their medical titles in the background, and are addressed as captains, colonels, majors, lieutenants, etc.

While our forefathers warned us that one of the greatest dangers to the life of the Republic would be the development of military aristocracy, there seems to be in our little army of the present day a most extraordinary movement in this direction. In the medical corps of our army, which contains so many foreigners, a prominent medical officer who has enjoyed the exceptional rank and pay which our medical corps furnishes for many years, has only recently, if the report be correct, qualified as an American citizen.

I write this merely to ask if this system at present existing in the medical corps of the U. S. Army has the approval of the Secretary of War and of the general officers of the U. S. Army. If it has I should like very much to know it and if it has not I should like to be able to answer foreigners who point at it as a grievous inconsistency in our republican institutions.

Very respectfully yours, W. T. PARKER, M.D.
(Brief.) GROVELAND, MASS., Jan. 26, 1896.

W. T. Parker, M.D., asks information as to commissions of medical officers U. S. Army. Says that in the Navy and Marine-Hospital Service medical officers are known as surgeons, passed assistant surgeons, etc., while in the Army they are addressed as lieutenants, captains, majors, colonels, etc., and asks if this system has the approval of the Secretary of War and general officers of the Army.

Second endorsement.

WAR DEPARTMENT, SURGEON-GENERAL'S OFFICE, Jan. 30, 1896.
Respectfully returned to the Honorable the Secretary of War.

Medical officers of the Army are commissioned as assistant surgeons with the rank of first lieutenant, assistant surgeons with the rank of captain, surgeons with the rank of major, deputy surgeons-general with the rank of lieutenant-colonel, and assistant surgeons-general with the rank of colonel. In all official communications they are addressed in accordance with these designations. It is customary in social intercourse to address medical officers by their professional titles, and in my judgment there is no objection to this form of address. Some of our medical officers, however, insist upon being called by their military title. This is in accordance with the usage in other staff corps. There seems to be no question as to the

propriety of addressing a paymaster or a commissary or an adjutant-general by his military title; but in the case of a medical officer, upon whom the degree of doctor of medicine has been duly conferred, it would appear that in social and professional intercourse this title should have the preference.

GEO. M. STERNBERG, Surgeon-General, U. S. Army.

Third endorsement.

WAR DEPARTMENT, Feb. 1, 1896.

Respectfully returned to W. T. Parker, M.D., Groveland, Mass., inviting attention to the preceding endorsement hereon of the Surgeon-General U. S. Army. JOSEPH B. DOE.

Assistant Secretary of War.

The Pneumatic Dilator.

PHILADELPHIA, May 21, 1896.

To the Editor:—My attention has just been called to a passage in Dr. W. E. Owen's excellent paper on the "General and Special Treatment of Tuberculosis," in your issue of Jan. 11, 1896, which unintentionally of course upon Dr. Owen's part, is liable to be misconstrued into a recommendation by me of a certain instrument mentioned in the paper, Dr. Hawley's "pneumatic dilator." This apparatus may be capable of doing all that is said, but as I have never seen or used it, I can have no opinion about it specially worth expressing. The passage referred to is on page 67 and reads as follows: "By it [the aforesaid apparatus] the cardio-vascular and the pulmonary capacities are greatly increased, and to use the words of Solis-Cohen, 'resulting in increased function, increased elimination of waste products of function; with increased buoyancy of spirits which is no mean factor in treatment; in a word, heightened vitality.'" The remarks cited as from me (which, by the by, are not quoted *verbatim et liberatim* but slightly paraphrased) might, from the context, be thought to apply to the instrument exhibited by Dr. Owen. They are, however, a portion of my conclusions concerning the effect of *altitude* in stimulating nutrition in the prophylaxis or treatment of pulmonary tuberculosis, as may be seen by reference to page 789 of my article on Tuberculosis in Vol. I of "A System of Practical Therapeutics," edited by H. A. Hare, M.D., and published by Lea Bros. & Co., Philadelphia, 1891, from which they are cited.

I have so often and so positively expressed myself in favor of the use of pneumatic measures, and especially the inhalation of compressed air with exhalation into rarefied air, in the prophylaxis and treatment of pulmonary tuberculosis, under suitable conditions and in proper subjects, that I should not like this correction to be misunderstood as opposing any proper method of securing pulmonary expansion by pneumatic devices, though theoretically I should think the usefulness of the instrument mentioned in Dr. Owen's paper to be rather limited, and should not wish the efficiency of pneumatic treatment in general to be judged by the results such an apparatus can probably produce. But, apart from this, I believe it better that words written in connection with one therapeutic measure should not be applied, without full explanation, to another.

I have been very much gratified to learn from various expressions in Dr. Owen's thoughtful article that the views concerning the causation and the proper treatment of tuberculosis and especially of pulmonary tuberculosis, which I have put forth in the work alluded to, have favorably impressed one so careful as an observer and so clear and forcible as a writer. The larger my experience becomes, the more firmly am I convinced that our great object in the prevention and in the therapeutics of this affection, should be to increase the vital, *i. e.*, the resisting and recuperative powers of the organism in general and of the pulmonary tissues in particular. Neither drugs nor antitoxins can effect this. They may help, but they are secondary in importance.

Very truly yours,
SOLOMON SOLIS-COHEN.

"Can Such Things Be?"

ATLANTA, GA., May 12, 1896.

To the Editor:—In an Atlanta daily paper of this date I find the enclosed item, which fully explains itself:

WHAT MISS CLARA BARTON SAYS OF AN AMERICAN INVENTION.

Constantinople, Feb. 21, 1896. —When in London the other day I received two packets from the United States embassy, each containing an Electropoise. To-day I received your kind letter and The Journal.

Allow me to thank you heartily and gratefully for the splendid little machines. As you remember, I am not altogether a stranger to the virtues of the Electropoise (saw its work in Jacksonville, Fla., in 1888), and I will take great pleasure in passing your offering to afflicted humanity through my medical staff. I feel assured the physicians will avail themselves of such valuable aid.

Very sincerely yours,

CLARA BARTON.

In reply to a letter asking permission to publish the above, Miss Barton writes under date of April 23, through her private secretary, the letter given below:

Constantinople, April 23, 1896. —Your letter of request was duly received. Miss Barton has no objections to your publishing her letter, if by so doing the wonderful little instrument will be still more gratefully received by suffering humanity.

Very truly yours,

G. H. PULLMAN, Private Sec'y.

The item closes with mentioning the agents' names and office, and with the statement that any information about the "splendid little machines" will be cheerfully given by said agents.

Every one admires Miss Barton for her noble work and life of self-sacrifice which she has been engaged in for many years. Her use and indorsement, however, of the very worst of the patent frauds is, to say the least, a new departure, and not a consummation devoutly to be wished by any means.

Yours very truly,

L. B. GRANDY, M.D.

Injection of Antitoxin.

WHEELERSBURG, OHIO, May 19, 1896.

To the Editor:—Referring to Eulenberg's contention, as reported in the last number of the JOURNAL, that the sudden death of a healthy child at Hoechst-on-Main after an injection of antitoxin, could not have been due to the virulence of the serum, but was perhaps the result of embolism, the puncture of a vein, or the introduction of air, may it not be pertinent to inquire whether ordinary hypodermic medication as heretofore practiced by all classes of physicians, has been followed by sudden deaths similar to those reported after the use of antitoxin?

JAMES L. TAYLOR, M.D.

PUBLIC HEALTH.

"Domestic Medicine" Popular in Prisons. —It is recorded that in one of the large English prisons the favorite book in the library for the use of the prisoners, was that of Buchan's "Domestic Medicine." At first the curious fondness of the inmates for such a work was not apparent, but subsequently it transpired that the prisoners, anxious to play the rôle of malingerers and so escape their tasks, laid themselves out, with the help of the volume, to study carefully the symptoms of certain diseases with a view to deceive the prison surgeon.

Something Tangible in Sanitary Administration against Tuberculosis (Bovine). The French government has decreed that all cattle imported into France from foreign countries must be tested with tuberculin at the frontier before being admitted. In those cases in which the characteristic reactions denoting the existence of a tuberculous process are revealed the animals are, after being marked, refused entrance into the country unless the owner gives his consent to immediate slaughter. The tuberculin test is not applied to cattle which are formally declared to be imported for slaughtering purposes. In these cases, however, proof must be forthcoming within fourteen days that the animals have been killed in the presence of an inspector.

Smallpox on the Isle of Man in the 18th Century.—Dr. Charles Steele, of Clifton, sends to the *British Medical Journal*, certain interesting extracts from the parish register of Ballaugh church, Isle of Man, which gives the deaths in that parish from 1704 to 1799 from smallpox and other causes. Within that period smallpox killed in this small parish 166 persons, while the deaths from all other causes numbered only fifty. In fact, three out of four persons whose burials were registered in the parish met their death from smallpox. And yet there are a substantial number of our population who wish to go back to the eighteenth century for our treatment of the disease.

Amendment of Colorado Pharmacy Law. Sections 10 and 12 of the pharmacy law passed in Colorado in 1893 were amended in 1895; the former, raising the penalty from \$25 to \$250 for any person other than a registered pharmacist retailing or dispensing drugs; the latter, by incorporating a provision that the pharmacist failing or neglecting to procure his annual registration, or any person making any false representations to procure for himself or for another registration, or any person violating any other provision of this act, shall for each and every offense be liable to a fine of \$100.

Provision for Lost Diplomas in Florida.—Section 806, chapter 4, of the Revised Statutes of the State of Florida, provided for the examination, by the board of examiners, of the applicant for a certificate of qualification to practice medicine, "upon the production of his medical diploma from a recognized college." This the legislature of that State amended in 1895, by adding in this connection, "or in the event said applicant shall have lost his diploma, or the same shall have been destroyed prior to the year 1870, then upon satisfactory evidence to such board of such loss or destruction."

California Coroner to Appoint Physician.—In counties of the first class, it was enacted in California in 1895, the coroner shall appoint a competent physician, whose duties it shall be to perform autopsies upon the bodies of all deceased persons when inquests are held. Such physicians shall, after the performance of such autopsy certify in writing his professional opinion as to the cause of death, which certificate shall be filed with said coroner. The physician so appointed shall receive as compensation for such services \$2,400 per annum, to be paid out of the general fund of the county in monthly installments of \$200 each.

Improved Health Rate of Rome.—The following note from the *Medical News* shows the vast strides of sanitary improvement that have been made at Italy's capital: "Roman fever is almost a thing of the past. From 650 in 1881, the deaths from malaria ran down to 254 in 1891, while for the last five years the average has been 149, the number in 1895 being 125. These figures are all the more significant in that the population of Rome has increased from 300,000 to 467,000 in fifteen years. An equally remarkable diminution has taken place in the death rate from all other infectious diseases, so that Rome, even in the traditional unhealthy season, is one of the most healthy capitals in Europe."

Sewer-Gas Dangers Affecting Tall Buildings.—Sanitary Engineer C. F. Wingate writes to one of the New York City dailies that he has observed a danger from tall buildings, that has not been noted by others, namely the discharge of filthy sewer-gases from soil-pipes of comparatively low houses into the windows and light-shafts of adjacent occupied rooms. He instances one striking instance where "the entire family of the superintendent of a large office building, occupying spacious rooms on the roof, surrounded by lower buildings, but with a magnificent outlook over the harbor, have suffered from severe forms of zymotic disease, including repeated attacks of malarial fever, so that the family have been nearly decimated, and have

been forced to abandon their apparently ideal quarters. Growing plants were destroyed by the virulent odors which penetrated their rooms, so that it was impossible to open windows, or to occupy the apartments for living purposes."

New York City Board of Health and Its Anti-expectoration Ordinance.—On May 12 that Health Board adopted the following ordinance, to disobey which is a misdemeanor punishable by fine or imprisonment or both:

SEC. 222. Spitting upon the floors of public buildings and railroad cars and of ferryboats is hereby forbidden, and officers in charge and control of such buildings, cars and boats shall keep posted in such public buildings and in such railroad cars and in such ferryboats a sufficient number of notices forbidding spitting upon the floors, and janitors of buildings, conductors of cars and employes upon ferryboats shall call the attention of all violators of this ordinance to such notices.

The full Board voted for the resolution.

Practical School Hygiene.—At the meeting of the Auxiliary Sanitary Association of the Illinois State Board of Health in Springfield, October 22 and 23, action was taken looking to a radical improvement in school hygiene. A committee was appointed to confer with the State Superintendent of Public Instruction and the several County Superintendents of Schools with a view to drafting an amendment to the State school law requiring teachers to qualify physically as well as mentally before receiving certificates entitling them to teach—that is to say, that they shall at least be free from the danger of conveying pulmonary tuberculosis to the scholars under their charge; making a thorough knowledge of school hygiene a requirement for the certificate; and placing all public schools under medical supervision to the end that children presenting symptoms of any contagious disease may be examined by the duly appointed school physician, and on his authority referred to the family physician, to be admitted to school again only on the certificate of the latter. As 101 County Superintendents are counted on as friendly to this proposed legislation there is ground for favorable action thereon by the next General Assembly.

The Iowa Public Health Association held its fifth annual session at Davenport, May 19-20. Interesting papers on sanitary and hygienic subjects were read and the following resolutions favoring the establishment of a National Bureau of Health unanimously adopted:

WHEREAS, The discharge of sewerage into streams, ponds, lakes or other bodies of water is a serious and rapidly growing menace to public health by polluting the sources of water supply to a dangerous degree, and

WHEREAS, The power of the State committee or municipality is wholly inadequate to check or in any way control the most pernicious method of sewerage disposal;

WHEREAS, We believe the authority of the Federal Government is absolutely necessary to put a stop to the growing evil, therefore be it

Resolved, That the Association most earnestly desires and would most heartily approve the creation of a National Bureau of Health, among whose functions should be the control of all rivers, streams, lakes, ponds or other bodies of water, with reference to their sanitary condition.

Resolved, That the State Board of Health of Iowa and the State Board of Health of Illinois and that of Minnesota be requested to take as promptly as possible such action as shall lead to the drafting and formulating of a petition to Congress asking that a National Bureau of Health be created, or otherwise putting the necessary machinery in motion that this very important end may be obtained.

Not American Stock this Time.—Close upon the most recent of the repeated interdicts of American meats by hostile foreign governments comes a cable dispatch announcing that the food purity scare which has been so tenderly fostered by the agrarian politicians of Germany has received a sensation fillip by the seizure last week of 400 pounds of food infected with tuberculosis at the Berlin Trades Exhibition in the institution devoted to the sale of cheap food to the public, where thou-

sands of persons eat dinners daily that cost a penny a head. The infected meat came from Mecklenburg, and not from America, which country the German officials profess to regard as the place of origin of all of the diseased meats in the world.

In spite of the dictum of Baron von Hammerstein-Loxton, Prussian Minister of Agriculture, Domains and Forests, that it is impossible to put a Chinese wall around Prussia to prevent the importation of foreign animals, the provincial Governors have one after another closed their boundaries against the adjoining provinces, on the ground that the animals raised in the proscribed provinces are infected with foot and mouth disease and ailments of that kind, and now the frontier of Prussian Silesia has been closed against Russian hogs.

The *Reichsanzeiger*, the official organ, publishes a notice issued by the Governor of Dusseldorf, in Rhenish Prussia, closing the markets of that province against sixty districts throughout the empire, among which are Hamburg, Königsberg, Breslau, Magdeburg, Lüneburg, Wiesbaden, Cologne, Aachen, Dresden, Leipzig, Carlsruhe, and Mannheim, besides provinces like Mecklenburg, Saxe-Weimar, Brunswick, etc. In fact, there has never been such a sweeping charge of infection printed in Germany.

Malarial Conditions in Eastern Carolina; Artesian Wells needed.—In the *Bulletin* of the North Carolina Board of Health, for April, Dr. Julian Baker of Tarboro, discusses the conditions of the eastern section of his State as follows:

"The topographic and meteorologic conditions in Eastern Carolina furnish a most suitable environment for the life of the malarial germ: so our effort must be directed primarily to the prevention of the development of the germ outside of the body, and then its entrance into the body. Notwithstanding the fact that Sternberg failed to find the germ in the marsh mud of Louisiana, the low marshy lands of the Roman Campagna, the bottom lands of Mississippi, Arkansas and Alabama, and the low lands of our section are too familiar as favorite localities for the worst forms of malaria to controvert the fact that heat, moisture and decomposing vegetable matter constitute the favorable environment which we must first remove in order to prevent the germ's development. It is inexplicable at presents that these marshes and low lands have been known to become healthy without apparent change in previously favorable conditions for development; it is highly probable, though, that the germ will never disappear unless the environment is changed. Clearing, draining and cultivation will accomplish this in a measure. Oxygen being necessary, as claimed by Crudeli, to the existence of the germ, close sodding with grass after drainage is the best sanitary cultivation. The Carolina poplar or cotton-wood tree, eucalyptus and several others, have gained a reputation as absorbers of the virus from miasmatic atmospheres."

Doubtless one tree is as good as another for this purpose, and the claim of those mentioned is referred to, only to deny it absolutely. In Eastern Carolina the water supply is principally from shallow wells, ten to twenty feet deep, in wet seasons the water rising very near the surface level. The question of prevention resolves itself into one of purifying the water from shallow wells, or getting purer water from some other source. By boiling the well water all vitality is destroyed and dead organic matter is harmless. This is the only safe rule if any well-water is to be used.

"The custom prevails in some malarial sections to boil enough water in the morning for the day's consumption. After boiling it should be placed in a porcelain cooler and closed up. By using only boiled water the malarial attacks may be reduced to a minimum. It is a matter of common observation that, in families using boiled water, those who, for some reason do not drink it have been known to have malarial attacks while the others escaped. Purer and better water can be obtained from deeply bored or driven wells and cisterns. When proper care is exercised in collecting, no better water can be procured than cistern water. The Board of Health has done great good in disseminating information in regard to bored wells. They are coming into more general use, and wherever used malaria prevails to less extent: but the pump gets out of order, is troublesome to repair, and doubtless too, after a while, unless very deep, these wells become contaminated and their use is discon-

tinued. Artesian wells, where practicable, will fill all the requirements of pure drinking water, except in very rare instances. Their use is beginning to attract attention everywhere. Experimental wells are being sunk in many places, and no good reason exists why artesian wells should not be generally used in our section. Eastern Carolina needs purer drinking water. This can be obtained by boiling ordinary well water, by using cistern water properly collected, deep bored or artesian wells. Let our people realize this and put it into practical operation, and Eastern Carolina becomes at once the healthiest, the richest and the grandest section of our Commonwealth."

Health Reports.—The following health reports have been received in the office of the Supervising Surgeon-General Marine-Hospital Service:

SMALLPOX—UNITED STATES.

Florida: Pensacola, May 20, 1 case.
Michigan: Ionia, May 16, smallpox reported.
Tennessee: Memphis, May 16 to 23, 4 cases.

SMALLPOX—FOREIGN.

Alexandria, April 16 to 22, 2 deaths.
Bristol, May 2 to 9, 4 cases.
Buda-Pesth, April 8 to 29, 9 cases, 1 death.
Bombay, April 14 to 28, 77 deaths.
Calcutta, April 4 to 18, 10 deaths.
Callao, January 1 to April 1, 141 deaths; April 1 to 19, 10 deaths.
Cardiff, May 2 to 9, 2 cases.
Gibraltar, May 3 to 10, 1 case.
Guayaquil, April 24 to May 1, 5 deaths; May 1 to 8, 5 deaths.
Madras, April 18 to 24, 1 death.
Madrid, April 28 to May 5, 13 deaths.
Naples, May 2 to 9, 7 cases, 3 deaths.
Odessa, April 25 to May 2, 27 cases, 2 deaths.
Prague, April 25 to May 2, 3 cases.
Rotterdam, May 2 to 9, 1 case.
Rio de Janeiro, April 18 to 25, 3 deaths.
Trieste, April 18 to May 2, 1 case.
Tuxpan, April 25 to May 2, 1 case, 1 death.
Warsaw, April 25 to May 2, 4 deaths.

CHOLERA.

Alexandria (Egypt), April 16 to 22, 7 deaths.
Bombay, April 14 to 28, 19 deaths.
Calcutta, April 4 to 18, 565 deaths.

YELLOW FEVER.

Brazil: Ceara, March 1 to 31, 3 deaths; Rio de Janeiro, April 18 to 25, 96 cases, 68 deaths.
Cuba: Sagua le Grande, May 11, yellow fever reported.

BOOK NOTICES.

Fifteenth Annual Report of the State Board of Health of New York. Transmitted to the Legislature March 6, 1895. Albany, N. Y. James B. Lyon, State Printer. Pp. 775, 8vo, cloth, with supplement containing 18 maps.

This report is one of the best that this Board has yet produced. The Board does not devote much time to pedagogics, but goes "straight on" furnishing aid to towns and local boards of health, a complete report whereof will be found in this volume, with the maps showing the plans of sewerage and sanitary improvements.

In 1894 the State Legislature appointed a special commission on tuberculosis in cattle in the State of New York, and in this report a statement of the operations of the commission is given. The report states:

"Tuberculosis causes one in every eight deaths in this State, according to the statistics of the State Board of Health. No other disease approaches this as a cause of mortality to the human family. There is a complete unanimity of opinion now, in the scientific world as to its communicability from man to man, and from animals to man, and man to animals. That milk and its products will convey it, has been proven repeatedly. This has now passed beyond the experimental stage, and is no longer open to doubt. It has also been proven that lower animals fed with tuberculous meat become tuberculous as a result of such feeding.

"It may be accepted as a fact that milk from tuberculous cows in which the udders are distinctly affected, contain tubercle bacilli, and that such milk is a dangerous aliment, and that sterilization would not render it a desirable nutrient material, because of other poisonous products contained in it as a result of the disorganization caused by the disease. When it is considered that milk is the principal aliment during childhood and enters largely into the dietary for all ages, it is a highly important question.

"The channel of infection is more likely to be through the alimentary tract, since recent investigations have shown that the sun's rays are inimical to the bacilli tuberculosis. The danger of infection through the respiratory tract is therefore lessened.

"The New York State Board of Health examined 22,000 cattle during the year, and one-half following the passage of the tuberculosis act, and of this number, caused to be slaughtered about 800. So important was the work thought to be that the commission on tuberculosis in cattle was constituted on the 31st day of May, 1894, to further inquire into the existence of tuberculosis in cattle. During the short time since its creation this commission has carefully studied, by a system of special inspection, the prevalence, distribution, mode of infection and general behavior of tuberculosis in cattle, confining part of its work to a given area, which was thought to be comparatively free from general infection from other sources. In this district 947 animals were examined, and out of this number 66 were condemned and slaughtered. A dissection of each animal showed it to be tuberculous, showing 6.96 per cent. diseased, and it is believed that this is fair average if the State were taken as a whole. A large proportion of these animals were common stock, which fact controverts the opinion which obtained very generally hitherto, that common bovine animals have immunity from tuberculosis. Tuberculosis is not a respecter of breeds. The disease once introduced into a herd, spreads with certainty throughout, and with a rapidity proportionate to the insanitary surroundings. Cattle kept in well-ventilated stables, with free admission of sunlight, are less prone to the disease, while those kept in dark, ill ventilated stables, amidst filth and insanitary environments, develop the disease rapidly once it is introduced.

"The investigations of this commission have shown that tuberculosis is, under certain conditions, congenital, but its general diffusion is due to contagion. But a very small proportion of tuberculosis is disseminated by transmission. All the facts in the possession of this Commission, as a result of investigation, show that tuberculosis spreads with certainty when diseased and healthy animals are housed together. The contagiousness of the disease is established beyond a doubt, for in most cases, it can be traced from herd to herd in localities where dairymen deal with each other in the purchase of cattle from infected herds."

Yearbook of the United States Department of Agriculture, 1894. Government Printing Office. 8vo, cloth, pp. 608. Washington: 1895.

Of all the departments of the Government, few have made more progress in general usefulness than the Department of Agriculture. This has been almost entirely due to its scientific Bureau. This yearbook is a new departure and will surely increase the popularity of the Department.

This volume is divided into three sections:

1. Report of the Secretary for 1894, giving a general account of the operations of the Department.
2. Essays and papers by chiefs of Bureaus and divisions, on their general work, and on special studies of interest to the farmer.
3. An appendix made up of statistical tables useful for reference.

The contents of this yearbook are: 1. Report of the Secre-

tary. 2. The Federal Meat Inspection by D. E. Salmon. 3. Education and research in Agriculture in the United States by A. C. True. 4. What Meteorology can do for the Farmer, by M. W. Harrington. 5. Value of Forecasts, H. C. Dunwoody. 6. Soils in Relation to Crop Production, Milton Whitney. 7. Water as a Factor in the Growth of Plants, by B. T. Galloway and A. F. Woods. 8. Mineral Phosphates as Fertilizers by H. W. Wiley. 9. Fertilization of soil as Affecting the Orange in Health and Disease, H. J. Webber. 10. The Geographic Distribution of Animals and Plants in North America, C. Hart Merriam. 11. Hawks and Owls as related to the Farmer, A. K. Fisher. 12. The Crow, Blackbirds and their Food, F. E. L. Beal. 13. Some Scale Insects of the Orchard, L. O. Howard. 14. The more Important Insects Injurious to stored Grain, F. H. Chittenden. 15. The Dairy Herd; its Formation and Management, H. E. Alvord. 16. Suppression and Prevention of Bovine Tuberculosis, Theobald Smith. 17. Pasteurization and Sterilization of Milk, E. A. De Schweinitz. 18. Food and Diet, W. O. Atwater. 19. Pure Seed Investigation, G. H. Hicks, and eight other articles peculiarly relating to the farm. The yearbook of the Agricultural Department has "come to stay."

Borderland Studies, Miscellaneous Addresses and Essays, pertaining to medicine and the medical profession, and their relations to general science and thought by GEORGE M. GOULD. Formerly editor of *Medical News*, Philadelphia: P. Blakiston, Son & Co. 1012 Walnut Street. 8vo, cl., pp. 380. Price \$2.

The profound scholarship, the keen judgment, and the humor which pervades Dr. Gould's writings are destined to make them popular. Although a shudder goes through one when some old time image is swept away by a single stroke of the sword, yet we must admit that if there were no iconoclasts there would be no progress in civilization. If there were no reformers there would be no reform; if there were no revolutionists, governments would go on forever, grinding the poor and laying additional burdens on the patriotic; the chains of the slave would clank to deaf ears, and the race become covered with the dust of antique custom.

There is another thing that is evident in all the writing of Dr. Gould, and that is the absolute sincerity of the man. No weak or foolish sentiment appears in any article; it is entirely clear that he believes what he writes, and equally clear that no motives of policy govern. Whether perpetrated by friend or foe a wrong is a wrong, and as such to be pilloried. A master of satire, he rarely uses it for personal punishment, but merely for decorative purposes.

In this book we find some of the more thoughtful of the editorial articles as published in the *Medical News*, and essays published in the *Monist* and the *Open Court*. This volume places them on permanent record; even when one can not agree with all of them he must feel that medical literature is enriched by their preservation and the standard of American scholarship sustained by able hands.

Twentieth Century Practice, an International Encyclopedia of Modern Medical Science by leading authorities of Europe and America. Edited by THOMAS L. STEDMAN, M.D., New York city. In twenty volumes. Vol. V. Diseases of the Skin. New York: William Wood and Company. 1896.

The contributors to this volume, with perhaps two exceptions, are well-known writers on dermatology, and several have text-books of their own. Surely, the duty of fairly depicting the state of knowledge on this subject could not have been intrusted to abler hands.

Charles W. Allen, M.D., New York; John T. Bowen, M.D., Boston; L. Brocq, M.D., Paris; L. Duncan Bulkley, M.D., New York; H. Radcliffe Crocker, M.D., London; James Nevins Hyde, M.D., Chicago; Moriz Kaposi, M.D., Vienna; H. Leloir, M.D., Lille; D. W. Montgomery, M.D., San Francisco; Arthur Van Harlingen, M.D., Philadelphia, and H. Whitehouse, of New York, are the contributors. The text is brought

up to date, the illustrations are excellent, and the publisher's part of the book is all that could be desired. This volume is a worthy companion to the other excellent ones of the series.

Transactions of the American Orthopedic Association, Ninth Session, held at Chicago, Sept. 17-19, 1895, Vol. VIII, 335 pages, 8vo, cl.

It is printed in clear type on fine paper, and illustrated with numerous cuts showing deformities and the apparatus for their treatment, some new to the profession. The society has fifty-two active and twenty-one corresponding and honorary members, and this list includes the names of many of the most prominent workers and writers on orthopedic surgery in the United States and foreign countries. The volume contains lists of officers and members, active, honorary and corresponding; constitution and by-laws, and thirty-eight papers by men of well-known ability.

The volume will be read with interest and profit by all surgeons interested in orthopedic work.

The following are the officers for the ensuing year:

President, Dr. Samuel Ketch, New York, N. Y.

First Vice-President, Dr. H. M. Sherman, San Francisco.

Second Vice-President, Dr. W. R. Townsend, New York, N. Y.

Treasurer, Dr. E. G. Brackett, Boston.

Secretary, Dr. John Ridlon, 103 State Street, Chicago.

City of St. Louis Health Department, eighteenth annual report of the Commissioner, for the year ending March 31, 1895.

This report of Dr. Homan is more than usually interesting. In addition to the report of the Health Commissioner the annual statements of subordinate officers, and of the superintendents of the City Hospital, Insane Asylum, Female Hospital, Poor House, and of the Physician to the Quarantine and Smallpox hospitals. "St. Louis," says Dr. Homan "is the focal point of all this drainage¹ and must bear the brunt of the attack as best she may, no place of any considerable size below drawing public supplies from the channel of the Mississippi, therefore the means of prevention and correction should be most diligently considered here and now." He therefore recommends the Smart bill to appoint a National Commission for the investigation of the pollution of water supplies where such pollution affects or threatens to affect the water supply of more than one State. It is to be regretted that the bill has not been favorably considered. That is one of the matters that the new department of Public Health will have to take up, when it is established.

Transactions of the New York State Medical Association for the Year 1895. Vol. XII. Edited for the Association by E. D. FERGUSON, M.D., of Rensselaer County. 8vo, pp. 603.

It contains a list of presidents and vice-presidents from the founding of the Association in 1884. Darwin Colvin, M.D., Clyde, is president, and E. D. Ferguson, M.D., Troy, secretary for 1895-96. Among the many valuable papers appears the address of the retiring president, Austin Flint, M.D., New York, on "The Coming Role of the Medical Profession in the Scientific Treatment of Crime and Criminals." E. H. Squibb, M.D., in his paper, "Brief Comments on the Materia Medica, Pharmacy and Therapeutics" of the year ending Oct. 1, 1895, gives in concise form a résumé of observations of effects of many of the newer additions to the pharmacopeia.

Obstetrical Accidents, Emergencies and Operations, by L. C. H. BOISLINIERE, A.M., M.D., LL.D. Late Emeritus Professor of Obstetrics in the St. Louis Medical College, etc. Illustrated. Philadelphia: 1896. W. B. Saunders, 925 Walnut Street. 8vo., cl., pp. 381. Price \$2.00.

This handbook comprises the essentials of the branches set forth in the title conveniently arranged and admirably stated. It seems to very happily present in a small compass the present teachings of the art. The publisher has well performed

¹ From the Illinois and Missouri Rivers.

his part of the book by furnishing excellent illustrations. It is a book which will be of great service to students, and as well to young practitioners, for everybody knows that the young obstetrician invariably has the most desperate cases.

A Compend of Gynecology, by WILLIAM H. WELLS, M.D., with 150 illustrations. Philadelphia: 1896. P. Blakiston, Son & Co. Price 80 cents. cl., pp. 262.

This is an excellent book of its class, well printed, profusely illustrated, and admirably compiled. Some of the larger books might study this book as an object lesson in the department of condensation.

A Compend of Diseases of Children, by MARCUS P. HATFIELD, A.M., M.D., 2d edition. Revised. Philadelphia: 1896, P. Blakiston, Son & Co. Cloth, pp. 220. Price 80c.

Another aspirant for classroom honors, is found in Dr. Hatfield's compend. It is with pleasure we note that the author has used the reformed spelling, and the metric system. There are few errors and the arrangement is excellent.

Proceedings of the Philadelphia County Medical Society, Vol. XVI, Session of 1895. ALFRED STENGEL, M.D., Editor. 8vo, cl., pp. 400.

It contains, in addition to lists of officers and members, forty-seven papers on the various branches of medicine and surgery, many of them valuable additions to the literature of the subjects on which they treat. The society now numbers nearly 700 members.

NECROLOGY.

ORIN D. TODD, M.D., of Eminence, Ky., died in Louisville on May 4. He had been ill for about six weeks. He suffered with a complication of troubles and died with symptoms pointing to serious lesion of the kidneys. Dr. Todd was 53 years old. His early education was obtained at the local schools of Eminence and his medical education was received at Jefferson Medical College at Philadelphia, graduating soon before the outbreak of the war, during which he served as a surgeon; at the close of it he settled in Eminence, residing there continuously until his death. He was a railroad surgeon of some prominence, and served as referee for the State Board of Health in Henry County since the passage of the Medical Practice Law a few years ago. He has been vice-president of the Kentucky State Medical Society and a prominent candidate for the presidency. No man had more friends than Dr. Todd and his death is a personal loss to many throughout the State as well as in his own county. No gathering of the State Medical Society was complete without Todd, and he was always down on the program to answer the toast of the "Ladies" or the "Absent Ones," which was always full of mirth and pleasantries, though he was unmarried. He was a most generous and noble soul, generous when it was to his interest to be otherwise; charitable always; happy, bright and cheery at the bedside of the sick; a comforting friend to the dying; a typical friend in need; generous and loving to his friends and kind and charitable to the stranger within his gate. His heart was a most genuine one, a lover of fun, a great, noble man with the heart of a great, noble boy. At his home there was no public gathering where Dr. Todd was not a welcome visitor; there was no private entertainment where his smiling face did not beam a welcome and a benediction. As a friend said: "There was no man among us so sincerely loved and no man so much deserved that love; how sadly he will be missed only the people of Eminence can tell, and all that section of country as well."

CARLTON PENNINGTON FROST, M.D., LL.D., dean of Dartmouth Medical College, at Hanover, N. H., May 24, of heart disease. Dr. Frost was born in Sullivan in 1830. He fitted for college at Thetford Academy and graduated from Dartmouth in 1852. In 1855 he graduated from Dartmouth Med-

ical College, and from New York Medical College in 1857, with the degree of M.D. The degree of LL.D. was granted him by Dartmouth in 1890. From 1857 to 1862 he practiced in St. Johnsbury, Vt. Thence he went to the civil war as a surgeon of the Fifteenth Vermont Volunteers and acted as surgeon of the board of enrollment from 1862 to 1865. At the close of the war he settled in Brattleboro, Vt., where he practiced until 1871, when he became a lecturer on science and practice of medicine in the Dartmouth Medical College, and was appointed professor of the same subject in 1871. He has served as dean for twenty-nine years, and since 1881 he had been on the college board of trustees. He had also been a trustee of the State Asylum and president of the State Medical Societies of New Hampshire and Vermont.

EMMETT THOMAS GAMMAGE, M.D., of Brooklyn, died May 9. He was born in Northampton, England, in 1840. He studied medicine and graduated from the Royal College of Physicians and Surgeons. He lectured throughout England in the interest of the charter movement, and was indicted for sedition, but was never tried. He came to this country in 1868, and settled in Brooklyn, where his work as a music composer and critic gained him some fame. He has been prominently identified with many musical societies, and was at one time president of the Brooklyn Choral Union. His widow and two children survive him. His daughter, Florence Maud Gammage, is well known as a concert singer.

AMOS H. JOHNSON, M.D., of Salem, Mass., died May 12, aged 65 years. Dr. Johnson was born in Boston, August 4, 1831. He was educated at Chauncy Hall School, Phillips Andover Academy, was graduated from Harvard in 1853 and from the Andover Theological Seminary in 1856. From 1857 to 1861 he was pastor of the Congregational Church in Middletown, Mass. In the spring of 1862 he entered the Harvard Medical School, obtaining his degree in 1865. In 1866 he settled in Salem as a practicing physician, where he had been located ever since.

ST. GEORGE BRIDGES, M.D., at Richmond, Va., April 20, of appendicitis. He had made a special study of appendicitis and was considered an authority on that disease.—Emil Custer, M.D. (University of Würzburg, Germany, 1845), at Manchester, N. H., May 18, aged 76 years.—Thomas F. Hines, M.D. (College of Physicians and Surgeons, Keokuk, Iowa, 1892), at Middle Creek, Ohio, May 13.

SOCIETY NEWS.

The Louisiana State Medical Society held its seventeenth annual session at New Orleans, La., May 12 to 15. P. E. Achmard, M.D., Acting President, delivered the annual address. The program included a clinic each morning at the Charity Hospital.

Pennsylvania State Medical Society.—At the annual session held at Harrisburg, Pa., May 19 and 20, the following officers were elected for the ensuing year: President, Dr. E. E. Montgomery, Philadelphia; Vice-Presidents, Dr. C. O. Shaw, Allegheny County; Dr. F. P. Ball, Clinton; Dr. T. M. Livingston, Lancaster; Dr. A. C. Wentz, York County; Secretary, Dr. W. B. Atkinson, Philadelphia; Assistant Secretary, Dr. Adolph Koenig, Allegheny County; Treasurer, Dr. G. B. Dunmire, Philadelphia; Members of Judiciary Council, Drs. M. A. Rhoads, Berks; John H. Packard, Philadelphia; John Curwen, Warren; delegates elected to Pan-American Medical Congress are J. M. Anders and Ernest LaPlace, Philadelphia; W. F. Bacon, York; R. J. Ramsey, Franklin County; A. M. Miller, Lancaster; E. M. Corson, Montgomery County; F. F. Davis, Venango County. The next convention will be held at Pittsburg in September, 1897.

MISCELLANY.

Reading Room for Students.—A Paris medical journal, *Médecine Moderne*, has founded a free reading room for the benefit of the medical students of the Latin Quarter, and the success of the new departure has surpassed all expectations.

The Medical Cricketer.—Mr. W. G. Grace, the adored champion of cricket in England, has been honored by national testimonial the value of which is not far from \$45,000. The major part of this handsome gift has been invested in income-bearing securities. Mr. Grace was admitted to practice as a surgeon in 1879.

Period of Gestation.—The supreme court of Nebraska held, April 7, 1896, in the case of *Davison v. Cruse*, that the probable duration of the period of gestation is a question of fact, to be shown by proper evidence in each particular case wherein that question is material. In this respect it says it is quite analogous to the existence of negligence as contributing to personal injuries.

Need Not Make Out Prescriptions.—A druggist who is a regular physician, the court of appeals of Kentucky holds, April 15, 1896, in the case of *Lindsay v. Commonwealth*, need not make out for himself prescriptions prescribed and filled by him as such physician and druggist for others, and preserve them as a protection from prosecution, as for example under the Kentucky law, for selling liquor without a license.

Sacral Eschar Following Vaginal Hysterectomy.—Both Legueu and Villar have called attention to this possible consequence of vaginal hysterectomy. In one case, four days after a tedious operation in which an enormous fibroma had been removed, the patient complained of pain below the kidneys, and a very large eschar made its appearance, suppurating and much distressing the patient, accompanied by incontinence of urine and feces.—*Bulletin Médical*, April 8.

The First Female "Master in Surgery."—Miss Louisa Aldrich-Blake has achieved the distinction of becoming the first Master in Surgery of the University of London. She has, by winning this distinction, capped an honorable career as a student at the London School of Medicine for Women, having distinguished herself in every part of her student course. Miss Blake is Curator of the Anatomic Museum at the Royal Free Hospital, London.

A Valuable Prize Divided Between Drs. Roux and Behring.—The French Academy of Medicine has divided the Prix St. Paul of \$5,000 between Dr. Roux, of the Pasteur Institute, and Dr. Behring, of Berlin, for their discovery of the anti-diphtheritic vaccine. The *Figaro* says that a large number of German and English savants have accused Dr. Roux of having wished to take to himself all the credit of this discovery. The truth is that Dr. Roux has constantly refused every prize or reward, unless a part thereof shall have been granted to Dr. Behring.

The Reason for the High Price of Eunuchs.—In Egypt lads from 7 to 10, are castrated by cutting off at one stroke the scrotum and penis with a razor, after which the child is buried in dry sand almost to his neck, to check the flow of blood, for four or five days. Another method is to sever the penis by means of a stout cord tied around it, the ends of which are violently pulled. The pain of each method is intense, and two-thirds of the children castrated succumb to these barbarous mutilations.—*Bulletin Médical*, April 15.

How the Attendant got the Bath.—The following narrative is taken from an English journal: In the west country, in Somerset, two women became insane during the same week. The relieving officer, with the assistance of a female attendant, removed them to an asylum. While the relieving officer and the medical officer were absent from the room, the nurses came and mistook the patients, for while one was taken to the bath-

room the other was left behind, and in her place the attendant who came with her, despite her protests, screams and oft-repeated statement that she was not the patient, was removed, stripped and bathed.

A Variety of Streptococcus Refractory to Marmorek's Serum.—Mery has succeeded in isolating a streptococcus from a patient with malarial fever, which proved extremely virulent on mice and rabbits, and yet resisted completely the effect of Marmorek's serum, tested again and again. It resembles very much the streptococcus found in strangles. Mery thinks that his discovery explains the variable action of Marmorek's serum, which has no effect on the new streptococcus, while destructive to the usual kind.—*Bulletin Médical*, April 22.

Clinical and Experimental Study of Infarction and Rotation of the Spleen.—Urso describes two cases he has operated upon for wandering spleen, and reviews the twenty-six cases on record of infarcted wandering spleen, combined with a twisted pedicle. He thus presents the anatomic and clinical picture of this complication of ectopic spleen. He also produced similar conditions in dogs by ligating the splenic veins, and found that the rotation of the spleen, when it occurs suddenly, may produce the symptoms of an acute strangulation. Twisting the pedicle sometimes produced infarction, of an embolic character. Infarctus of the spleen, he stated, is caused therefore by some interference in the circulation in the branches of the vena lienalis.—From *Policlinico*, Nos. 1-3, in *Centralblatt f. Chir.*, May 2.

A Great Benefactor, Mr. Ledger.—The *Independent* has the following brief personal note regarding the declining years of a true benefactor of his race: "One of the great, but not much talked about benefactors of mankind, is still living and in excellent health at Kenmore, Mr. Ledger, who about forty years ago after many trials and hardships, introduced that variety of cinchona calisaya known as Ledgerana, into the island of Java, when it began to be feared that the careless and destructive methods of gathering it by the natives of its South American home would wholly deprive the world of it. But this variety is very rich in quinin, and the great London firm that handles the main part of the product are afraid the world will not need all that now is produced. It is estimated that the quantity of bark now produced every year is fully ten millions of pounds."

"Taking Poison."—The supreme court of Illinois handed down two decisions March 28, 1896, in which it holds that the term "taking poison," as used in a policy of life insurance, means the voluntary taking of poison, or an intelligent and conscious act. In the first case, *Travelers' Insurance Co. v. Dunlap*, the death of the insured was caused by his mistaking a bottle of carbolic acid for peppermint. In the second case, *Metropolitan Accident Association v. Froiland*, death resulted from chloral being taken by mistake for distilled water. Here the policy provided, "I agree that this insurance shall not be held to extend . . . to poison in 'any way taken, administered, absorbed, or inhaled.'" The words, "in any way," the court holds relate to the mode or manner in which the poison is taken, and not to the motive of the insured in taking it. In both cases the supreme court affirms judgments, rendered for the respective plaintiffs, against the insurance companies.

Antitoxic Property of the Blood of Animals.—Phisalix announces that animals considered refractory to poisons (adders, vipers, frogs) succumb to large toxic doses, while on the other hand, animals considered susceptible resist small doses. It is therefore merely a question of degree. In the same way, the blood or serum of refractory animals is antitoxic, and can neutralize a large quantity of poison. Inversely the blood or serum of ordinary animals is not sensibly toxic, and yet ten to fifteen centimeters of the blood of a guinea pig added to a fatal dose of poison will retard its action. There exists, therefore, in the blood a small amount of some antitoxic substance, and conse-

quently the refractory condition of certain animals is merely an exaggeration of the normal condition.—*Bulletin Médical*, April 22.

Test for Albumin in Urine.—Dr. Adolf Jolles, of Vienna, according to the *Medical Press and Circular*, has brought forward a new test containing mercury, succinic acid and the hypochlorite of soda. He maintains that a good test for albumin should be free from color and sensitive in reaction, and thought the following fulfilled these requirements:

R Hydrarg. bichlorid.	5	ijss	10
Acid. succinici	5	v	20
Sodii hypochlorit.	5	ijss	10
Aque distillat.	5	xv	450

After filtering 4 or 5 c.cm. of the urine to be tested, 1 c.cm. of 30 per cent. acetic solution is added, with 4 c.cm. of the above reagent. The whole is well shaken and set aside to settle. In a second test tube, 4 or 5 c.cm. of the urine after filtration is treated with 1 c.cm. of the acetic acid as above and then set aside to settle in order to estimate the amount of mucin present. This eliminates any error from the absolute albumin present. The potassium ferrocyanid test is defective in this respect. The reaction is very sensitive and can detect 1 of albumin in 120,000 parts of urine. The reagent is free from color throughout, which is another advantage over the potassium ferrocyanid test. It is also superior to Spiegler's in defining accurately the amount present in the absence of chlorids.

A Missionary Hospital at Old Cairo.—The Church of England has through its veteran, Dr. Harpur, for several years conducted a little hospital of ten beds and a considerable dispensary work in the guardhouse of an old palace. Here from early morning often till late in the afternoon two doctors, English and Syrian, with their native assistants, are engaged in attending the sick and suffering. Since 1892 there has been a daily attendance of over 100, and during the past two years, of which a careful record has been kept, 10,849 persons have been treated, while 1,007 operations have been performed. The patients come from all parts of the country, even from as far as Suez, Assouan, Kafr-Zayat, Tantah and Zagazig, although, the largest number are from Old Cairo and the neighborhood. In 1894, 421 districts and villages were represented by the patients. In consequence of the large number of women attending the dispensary, the committee are sending out a lady doctor this year in addition to the present staff. The work is carried on under great difficulties, for the hospital is both inadequate and insanitary, and the whole accommodation of the mission is costly and uncertain. The committee of the C. M. S. have given a grant for the purchase of a site and for building houses for the doctors and lady workers, but a further sum of at least \$13,000 is needed for building the hospital and dispensary.

To Control Sale of Antitoxin in Connecticut.—A law was passed in Connecticut in 1895 that no person shall sell, offer, expose for sale, or shall receive or solicit any order for the sale or delivery, within that State, of any article known as diphtheria antitoxin, or any article prepared from the blood serum of any animal, and intended to be used for a medicine, unless the receptacle containing such preparation bears a label on which is placed the name and address of the producer, and upon such label, or upon a circular accompanying such receptacle, and inclosed with it in a sealed package, shall be printed or written the date of production and the value of the contents in antitoxin as measured by some generally recognized standard. Any person violating these provisions shall be fined not more than \$500, or imprisoned more than one year, or both. The State board of health may, from time to time, at its discretion, procure from any dealer in antitoxin or other blood serum medicine samples of such articles and cause the same to be tested, and if by such test it shall be found that the article tested is not such as it is represented to be on the package, but of infe-

rior quality, then the seller of such inferior article shall be punished as above. It shall be the duty of the county health officer in each county to prosecute violators of the provisions of this law.

Liability for Negligence in Making Examination.—The law does not exact from physicians and surgeons the utmost degree of care or the highest attainable skill in the practice of their profession, although they, by virtue of their relation toward patients, impliedly engage that they possess ordinary knowledge and skill, and that they will in the course of their employment exercise such proper care and attention as may be reasonably expected from members of their profession. Such is the statement of law made by the supreme court of Nebraska in connection with its decision of April 7, 1896, in the case of *Griswold v. Hutchinson*. This was an action brought against two physicians. The plaintiff alleged that he had employed them to treat his wife for what they pronounced an ovarian tumor, and that when they performed an operation therefor they found her only ailment was a fibroid tumor of the uterus, which fact they concealed from him. The court says that it was clearly established by the record that they were mistaken respecting its being an ovarian tumor. Some of the evidence in the case suggested that as careful an examination was not made as should have been for the purpose of determining on an operation. Indeed, the court says, on this point, that the testimony of the medical witnesses tended directly to prove the wrong alleged, viz., negligence in the examination, and the consequent unfortunate result thereof. On the trial, in the district court, judgment was entered in favor of the defendants on a verdict rendered in accordance with the peremptory instruction of the judge. The supreme court hold that this was error as to one of the defendants and reverses the judgment as to him. But as to the other defendant, Dr. Hutchinson, the court holds that the judgment in his favor was correct. When first consulted, he advised the plaintiff to consult some physician who was a specialist in that line, and his attitude toward the case after surrendering the patient to the other defendant was that of a friend and counselor only, and in no sense that of a physician or surgeon. On this ground the court exonerates him.

Practical Notes.

Favorable Influence of Strychnin in Chloroform Intoxication.—Evenchow states in *Wratsch*, No. 1, that in his experiments on dogs, he found that strychnin retards unmistakably the heart failure in collapse from chloroform, by its stimulating effect on the vasomotor center, which raises the lowered blood pressure.

First Trial at Kiev of Serum Therapy for Syphilis.—Wreden describes in the *Bolnitschnaja Gazeta Botkina*, No. 52, his experience with five young soldiers in the tertiary stage of syphilis, to whom he administered subcutaneous injections of mercurialized serum (10 c.cm.) It worked favorably from the first injection, diminished the pains and healed rapidly the ulcerations.

Alum Bougies.—Soak 5 parts gelatin in 35 parts water for 15 minutes, then add 10 parts glycerin and heat the mixture till it has evaporated to 40 parts. It must not boil, but can be kept at an even temperature by arranging the vessel at some distance above the heat. Add to this a warm solution of 1 part alum in 25 parts water, and heat until the mass become liquid again, and evaporate to 64 parts when it is ready to pour out. These bougies contain 12.5 per cent. alum.—*Bulletin de la Société de Pharm. de Bordeaux*, March.

Refuge for Pregnant Women and Mother's Milk Society.—These are two noteworthy benevolent institutions of Paris. In the former, women are received and physically cared for, while their work in a sewing-room attached, enables them to earn quite a little sum of money, which is given them when they leave. The children born average far higher physically than

usual. The other society supervises and assists mothers who have nursing children at their homes.

Retention of Dead Fetus. Labor Induced by Salicylate of Soda.—The fetus died at the fifth month and three months later the patient entered the hospital to be mechanically delivered. Nothing was done but to administer daily 6 grams of salicylate of soda for five days, when labor was induced and a natural delivery ensued. Vinay adds that medication alone is ineffective in inducing labor, unless the uterine contractions have already commenced, or unless some pathologic cause like the dead fetus, has produced a readiness in the uterus to respond. —*Gazette Médical de Liège*, April 30.

Straw Charcoal Recommended for Navel Bandages.—Wainstein describes in the *Shurnal bolesnej*, No. 10, a series of tests he has been making to determine the best material for navel bandages. The ideals of absolute cleanliness, rapid drying and healing are best secured by refraining from bathing, and by using the most absorbent bandage. This he asserts is straw charcoal (98 per cent.), after which come potassium permanganate and dry cotton. He also tried plaster of Paris, tannin, alum, glycerin and charcoal, and writes from an extensive experience, his views embracing the latest discoveries in regard to the superiority of hygroscopic bandages.—*St. Peters. Med. Woch.*, April 25.

Rectal Gonorrhea in Women.—Baer states that he has found this complication in 67 out of 191 cases of gonorrhea in women. He treats it with copious irrigation, using a 3 per cent. solution of boric acid, and to destroy the gonococci, a $\frac{1}{3}$ per 1,000 solution of argentamin. The erosions he paints with a 2 per cent. solution of argentamin. He has also found ichthyol effective.—*Deutsch. med. Wochenschrift*, February 20.

Tussol in Whooping Cough.—An epidemic of whooping cough gave a German physician the opportunity to test the virtue of tussol, which he found quite beneficial, in many cases restricting the duration of the disease to a couple of weeks. This JOURNAL, page 696, mentions another new remedy for whooping cough, chlorhydrate of phenocol. The practice of sending the little patient away from home is quite common, but it is strongly to be deprecated, as it often produces an epidemic in the place to which he is sent.—*Therapeutische Wochenschrift*, March 15.

Treatment of Wounds by Formalin.—Schleich announced at the Balneologic Society that he has discovered a new way of causing wounds to heal that renders the greatest triumph of modern surgery, antiseptis, entirely superfluous. With it there is no need for any carbolic or sublimate solution or iodoform gauze. The process consists in sprinkling pulverized gelatinized formalin in the wound, which produces some chemic change in the organism. The living cells take up the formalin, and it acts upon them in some way that has an accelerating effect upon the healing processes of the wound. Pus formations cease more rapidly than by any other method, while fever and inflammation subside immediately. He exhibited some patients operated upon a day or so previously, for various serious troubles, whose wounds had healed to a wonderful extent.—*Therapeutische Wochenschrift*, March 15.

Ether versus Chloroform.—Eisendraht has been studying the effect on 130 patients of the administration of these two anesthetics, testing the urine before and after, etc. He finds that preëxisting albuminuria is more frequently increased by the administration of ether than of chloroform. In healthy persons albuminuria is found in 25 per cent. of the cases after ether and in 32 per cent. of the cases after chloroform. Cylindruria follows the use of either in the same number of cases, 2 in all out of 130.—*Deutsch. Zeitsch. f. Chir. in Union Méd.* March 7.

Official Reports of the Antitoxin Treatment in Germany.—Replies

were received from 1,349 physicians to the circular sent out by the German government to collect statistics in regard to the treatment of diphtheria with antitoxin. The mortality in the 6,626 total cases treated, was 12.9 per cent. as a whole, and 19.5 per cent. in the hospital cases. There were sixty cases reported where the effect had been injurious, producing eruptions, albuminuria, pains in the articulations, cardiac troubles and nephritis, with three cases of general weakness. Forty-two of these recovered, and eighteen died. In 55.6 per cent. of the cases commented upon by the physicians, out of a total of 4,871, the beneficial effects of the serum were unmistakable. In 30.8 per cent. they were considered doubtful, and in 13.6 they were considered *nil*.

Non-Syphilitic Orbital Tumor Cured by Potassium Iodid.—Martin describes the case of a woman of 57, who applied to him for relief from pain in the orbit, more intense at night than during the day, with pronounced exophthalmus. The ophthalmoscope showed a venous stasis due to the compression of the optic nerve by a tumor. This pathologic condition had commenced eight months previously, after an attack of pleurisy. He supposed that it was a sarcoma, and as a waiting measure, he administered potassium iodid, one gram a day, intending to make an exploratory puncture and advise an operation later. But in one month there was marked improvement, and in two complete recovery. He adds that in similar cases this depuratory treatment should be followed, even when surgical intervention is necessary to prevent relapses, and states that not only potassium iodid is indicated, but possibly mercury, arsenic and various toxins, with whose properties we shall soon be better acquainted.—*Revue Gén. d'Ophtalmologie*, April 30.

Harrisburg.

THE PENNSYLVANIA STATE MEDICAL COUNCIL has rescinded its rules accepting licences from the New York Board of Medical Examiners. Physicians and surgeons who come into Pennsylvania hereafter from New York will be required to pass an examination before the State medical examining boards before they can practice, the same as those from other States and graduates fresh from medical and surgical colleges. The New York examiners have refused to accept the licenses issued by the Pennsylvania Council on the ground that the examinations in the State of Pennsylvania, are not up to the standard. A meeting of the council was held at which this retaliatory action was taken. The questions for the semi-annual examinations to be held June 16-20, were also prepared. The State Medical Board will conduct the examination in the senate chamber and house of representatives.

A HANDSOME PORTRAIT of the late Dr. T. J. Dunott, the Pennsylvania Railroad Surgeon and one of Harrisburg's best known physicians, who died in 1893, has been presented to the Harrisburg Academy of Medicine by Dr. J. F. Culp, of Steelton, Pa.

DR. HUGH HAMILTON of this city has been appointed secretary of the section on midwifery, diseases of women and abdominal operations in the second Pan-American Medical Congress.

Washington.

WEEKLY REPORT OF THE HEALTH DEPARTMENT.—The report of the Health Officers for the week ending May 16 shows: Number of deaths (stillbirths not included), 99; death rate per 1,000 per annum, 18.7; death rate per 1,000 per annum corresponding week last year, 17.1.

MEDICAL ASSOCIATION OF THE DISTRICT OF COLUMBIA.—The total membership of this Association is 358, not including 16 associate members.

MICROSCOPICAL SOCIETY.—At the twelfth annual reception, held on the 12th inst., seventy-five microscopes were in use, each exhibiting some interesting specimen, histologic or pathologic.

MEDICAL SOCIETY.—At the meeting held on the 13th instant Dr. Kerr read a paper on "Fractures of the Hip in the Aged,"

and Dr. V. A. Moore one entitled "Observations on the Number and Nature of the Bacteria Normally Found Present in Milk." At the meeting held on the 20th instant, Dr. S. S. Adams read a paper on "The Use of the Antitoxin of Diphtheria in Private Practice in the District of Columbia." Dr. Moore one on "Tuberculosis in Pigs," and presented some specimens showing the disease. The Society held a special meeting on the 18th instant to take suitable action on the death of one of its oldest and most respected members, Dr. Walter C. Briscoe, who died on the 16th instant at a sanitarium in Hopeworth, R. I.

DISTRICT HOSPITAL REPORTS.—The report of the Commissioner of Charities for the three months ended March 1, shows work done by the following hospitals:

The Central Dispensary and Emergency Hospital had 585 emergency cases, 89 ambulance calls and 10 autopsies; Columbia Hospital for Women had 499 medical and surgical cases treated, 87 operations performed and 1,335 prescriptions compounded; the Children's Hospital showed a total of 922 medical and surgical cases treated and 1,051 prescriptions compounded; National Homeopathic Hospital had 71 operations performed, 508 medical and surgical cases treated and 1,899 prescriptions compounded; in Freedman's Hospital there were 1,819 medical and surgical cases, and 1,340 prescriptions were compounded; the Women's Dispensary provided for 941 patients during the quarter; in the hospital of the Washington Asylum there were 171 patients received. Eight births occurred and 40 deaths.

WASHINGTON OBSTETRICAL AND GYNCOLOGICAL SOCIETY.—At the 247th meeting of the Society, held on the 15th instant, Dr. M. F. Cuthbert read a paper on the "General Management of Cases during Pregnancy and Confinement." Dr. Fry presented a uterus removed by abdominal section.

GEORGETOWN MEDICAL SCHOOL COMMENCEMENT was held on the 14th instant with eleven graduates.

CERTIFICATES OF HEALTH.—Senator Sherman has introduced a bill requiring all immigrants to the United States to exhibit upon landing in this country a certificate of health, signed by a medical officer of the Marine-Hospital Service, and providing that any immigrant who does not carry such a certificate shall be sent back to the port from which he came.

TO PREVENT CONTAGIOUS DISEASES.—Mr. Babcock has introduced in the House the bill of the Commissioners to prevent the spread of contagious diseases.

AGAINST THE VIVISECTION BILL.—Senator Gallinger presented a series of resolutions adopted by the AMERICAN MEDICAL ASSOCIATION, protesting against the passage of the bill regulating vivisection. Senator Proctor presented a memorial from Dr. Walter Wyman, Surgeon-General of the Marine-Hospital Service, and also a resolution adopted by the Pennsylvania Medical Society protesting against the bill, and there was also laid before the Senate a memorial from the Washington Chemical Society protesting against the passage of the bill.

DR. CARMICHAEL, of this city, who was operated upon at St. Luke's Hospital, New York city, on the 18th instant, for the relief of appendicitis, is improving rapidly.

Cincinnati.

CINCINNATI HOSPITAL.—The annual report of the Cincinnati hospital will be presented to the trustees next week, and will show an increase in work and usefulness. There is an effort being made to appoint an ex-boiler inspector superintendent of the hospital in place of Dr. F. M. Hendley. To those who will examine into the accounts, and the present condition of the institution in an unprejudiced manner it will be apparent that this would be a most deplorable move, for the staff would suffer the loss of several of its members who would resign in consequence, and surely the substituting of an inexperienced layman for a medical man of Dr. Hendley's experience and administrative ability would prove very detrimental to the hospital.

AN UNUSUAL CASE has appeared at Chillicothe under the care of Dr. S. Gorslene. A young man was bitten by a dog and in a few days began to manifest a most remarkable chain of symptoms. His skin resembled a week-old corpse, with general anasarca, marked dysphasia from laryngeal edema, articular inflammation, dyspnea and insomnia. He ranges from extreme violence to semi-consciousness. Other dogs who were bitten by this infected animal manifested the same symptoms as this case and they died in a few days in awful agony.

HEALTH OFFICER DR. J. W. PRENDERGAST has made several important recommendations in his annual report, among which are: The examination of cattle for tuberculosis by the injection of tuberculin; the establishment of an isolation hospital to consist of a number of small cottages located in the country, for the care of all city cases of diphtheria, measles, scarlet fever, etc.; and the erection of a disinfection station to be centrally located and where infected or suspected clothing, beds and furniture can be thoroughly sterilized by the most approved scientific methods at the expense of the city; dry air will probably be used.

THE WOMAN'S MEDICAL SOCIETY OF OHIO AND KENTUCKY was organized at a meeting held at the office of Dr. Ellen McCarthy, in the San Marco Building, May 22. The following officers were elected: President, Dr. Amelia J. Pryor, Cincinnati; Vice-President, Dr. Catherine Roebuck, Newport, Ky.; Secretary, Dr. Jessie Dillon, Cincinnati; Treasurer, Dr. Eliza Dickey, Cincinnati. The membership is limited to regular practitioners and the objects of the society are to encourage freer discussions of medical topics than are indulged in by the gentler sex at the Cincinnati Academy of Medicine, and to promote closer social relations between the members. The meetings are to be held bi-weekly.

THE BOARD OF MEDICAL EXAMINERS of the police department is wrestling with a knotty problem. Some months ago it ordered a number of policemen to exercise daily in the gymnasium in order to reduce their weight, and they have faithfully obeyed their orders, but in doing so a number have increased rather than diminished in weight, and now the question arises what influence will this have on the board when they pass on the fitness of the men for service?

THE LAURA MEMORIAL COLLEGE AND PRESBYTERIAN HOSPITAL held their annual meeting last Friday. The report of the medical department showed that 197 patients were treated in the hospital during the year. The receipts of the hospital from patients were \$3,303.98, making an average of \$32.06 from each patient. The expenses were \$6,317.29. A plea was made for free scholarships and better laboratory facilities.

ROBERT CAROTHERS has been appointed as one of the professors of surgery of the Laura Memorial College.

THE STATE BOARD OF MEDICAL EXAMINERS met at Columbus May 18 and discussed at length three important topics: The qualification of medical colleges; the licensing of opticians; and what constitutes the practice of medicine, this latter being left entirely to this Board to determine.

DR. W. H. DEWITT has been elected Medical Director of Christ's Hospital and Deaconess Home, to fill the vacancy caused by the death of Dr. C. G. Comegys.

THE MORTALITY REPORT for the week ended Friday, May 22, 1896, shows: Deaths from all causes 104; annual rate per 1,000, 15.42.

Detroit.

MEDICAL AND LIBRARY ASSOCIATION.—At the last regular meeting of this association, Monday, May 18, Dr. Guy L. Keifer read a paper on "The Antitoxin Treatment of Diphtheria," giving a general and brief report of cases which he had had under his personal observation. He verified the fact of its efficiency in prophylaxis, immunization and in treating after the disease is established, by the splendid results he had in his cases, and showed that it is not absolutely necessary to

have the treatment applied early, as in at least five of his cases the treatment was not applied until after the third day, when the disease had become well established. The Doctor cited a number of cases in which he had marked success, and in which he met with no deleterious effects with the exception of a slight localized pain at the seat of injection, and an eruption (urticaria) which appeared in some of his cases, from five to fourteen days after the injection, but disappeared rapidly. In order to give the serum treatment a thorough test he discarded all other treatment except the local application of a mild bichlorid solution, and such stimulants as he considered necessary. In all cases a milk diet was rigidly carried out. The mortality in the Doctor's cases which were not selected but treated in all stages of the disease, was one in fifteen or 6.66 per cent. In all the cases the temperature was reduced from one to three degrees within twelve hours after the use of the serum. In concluding his paper the Doctor said that in the future he for one would not feel justified in using anything but the antitoxin treatment, when he was convinced that he had a case of true Kleb's Loeffler diphtheria to manage.

THE WAYNE COUNTY MEDICAL SOCIETY, at its regular meeting, Thursday, May 21, listened to a very interesting paper by Dr. A. E. Carrier entitled, "Local Applications to the Skin." In the paper the Doctor pointed out the fact that pathologic lesions of the skin were identical in kind with those which occurred in other tissues of the body. The difference in symptoms being accounted for by a difference in structure of the organ in which the lesion occurs. Local therapy of the skin has two subjects in view, the relief of distressing symptoms, and the cure of the disease itself. He spoke of the great use that can be made of water. Tepid water macerates the epidermis. To prevent the parts from becoming sodden, we use salt, soda, or borax to increase the specific gravity of the solution, making it greater than that of the blood serum, and so preventing endosmosis. Water medicated with astringents, finds many opportunities for usefulness in parasitic affections, the water itself being of some use. On the other hand it is to be remembered that experience teaches us that many cases of eczema which will not yield to aqua solutions of certain preparations will readily yield the same preparations when used as ointments or powders. Soap finds a very valuable place in the treatment of skin disease. For simple cleansing, a neutral soap that has a slight excess of fat is the best. Soaps having an excess of alkali are very irritating and are to be used where we desire a stimulating effect. When used for this purpose the soap should be thoroughly rubbed into the part and then spread over it, and kept in place by a bandage for several hours. Soap may be the cause of many skin diseases. Ointments form a very valuable means of applying medicine, but they are something more than mere mixtures of fat and medicament. The coal tar products which form the basis of most salves are in themselves to some skins, irritants; but they have the valuable property of seldom becoming rancid. Decomposing salves or ointments work great harm. The consistency of the ointment is of great importance. It should be soft when we use it upon the scalp and should contain something to make it harder when we wish to get the prolonged action of the remedy. The ointment should not be used on surfaces containing an exudate as the effect of the drug is governed by the exudate. Powders are very serviceable preparations. Great care should be observed in preparing them, as from the mixture of the same, remedies of very different nature can be compounded. Powders are useful as protectives and absorbents.

HEALTH OFFICE REPORT for week ending May 23. Deaths under 5 years 25, total 70. Births, male 48, female 51, total 99. Contagious diseases: Diphtheria, last report 16, new cases 4, recovered 6, died 1, now sick 13; scarlet fever, last report 28, new cases 6, recovered 12, died 3, now sick 19; smallpox, none; measles, last report none, new cases 7.

Philadelphia.

UNIVERSITY OF PENNSYLVANIA.—Thomas McKean, Esq., Class of 1862, recently subscribed \$100,000 to the general fund of the University conditioned upon the raising of \$1,000,000 within a specified time. Provost Harrison has undertaken the task of completing the amount. Mr. Alfred C. Harrison has subscribed \$100,000 and J. William White, M.D., has promised to raise \$20,000. The annual commencement week is in June, and the examinations are now in progress.

JEFFERSON MEDICAL COLLEGE.—The 75th annual commencement was held at the Academy of Music. The address to the graduates was delivered by Prof. Theophilus Parvin, M.D., LL.D. The class numbered 227.

MEDICO-CHIRURGICAL COLLEGE.—The annual commencement of the college was held at the Academy of Music May 13, 1896, Dr. L. Webster Fox, Professor of Ophthalmology being the valedictorian. The number of graduates receiving the degree of M.D. was 54, in addition to which six took special courses.

THE SECTION ON GYNECOLOGY OF THE COLLEGE OF PHYSICIANS at its meeting on the 21st inst. had a varied and interesting series of papers. Dr. Robert H. Hamill presented a specimen and read the report on a "Case of Cesarean Section for Fibro-cystic Tumor Complicating Pregnancy, with Recovery of the Patient." By invitation of the Executive Committee, Dr. James F. Prendergast read a paper on "The Bicycle for Women." He considered that the advantages of this form of exercise when properly conducted, very greatly outweigh its objections and dangers. He stipulated, in the first place, that the person wishing to ride the bicycle should be taught a good method, so that the whole body should be exercised and not merely the lower extremities. Then a well adjusted saddle is of great importance, for women especially, and he praised the newer forms without any peak in front. Finally, the rider should not be permitted to indulge in the pastime to excess, at first, but should take up this form of exercise by degrees, so as not to cause undue amount of fatigue. With these precautions, he considers the bicycle a valuable adjunct to hygienic treatment and free from injury to the pelvic organs. Dr. Norris in discussing the paper, referred to a case of a patient suffering with lacerated perineum and relaxed muscles at the floor of the pelvis, who had refused operation and had become an enthusiastic rider of a wheel. A year later, he had again examined the patient and had found greatly increased tone and contractile force in the muscles of the pelvic floor, and such marked improvement that no operation was to be thought of. Dr. Longaker spoke of the height of the handles of some machines for ladies and condemned the very high handles equally with those which are too low. The handle-bar should be so adjusted as to allow the weight of the body to be distributed between three points, the pedals, the saddle, and the handles. In this manner of riding the exercise is extended to all the muscles of the trunk and limbs. Dr. Prendergast said that while a good saddle is not the only requirement it is a very important one, because very few women learn to support part of their weight upon the pedals in the act of riding on a bicycle. Dr. Richard C. Norris read the notes of "Three Cases of Tubercular Peritonitis" which had been subjected to operation. The difficulty of diagnosing this condition from ovarian cystomas was dwelt upon, and it was declared to be in some cases impossible to make out the condition positively before the abdomen is opened. The first case was submitted to celiotomy with removal of ovaries and tubes; universal peritoneal tuberculosis was found. She died in eleven hours, probably from tubercular toxemia, in the opinion of the reporter, although the possibility of a cryptogenetic infection, as suggested by Osler, was admitted. The second case, a colored woman 42 years of age, with symptoms of abdominal tumor and cachexia for a couple of years was subjected to laparotomy, removal of mass of tubercle and separation of adhesions between intestines, but the uterus and ovaries, being healthy, were not disturbed. Uninterrupted recovery followed. In the third case, a young colored girl, 17 years of age, a vaginal opening was made and tuberculous matter discharged; the symptoms having simulated a pelvic abscess. This patient also made a good recovery. The beneficial effects of operation upon peri-

toneal tuberculosis are observed in a very large percentage of the cases. The reason for this post-operative retrocession of the tubercular process in the peritoneum, and in the viscera of the abdomen was thought to be explained by the facts shown by experiments upon rabbits, that celiotomy is followed by increased resistance to infection and hyperemia, both of which are unfavorable to the further development of the tuberculosis. Dr. C. B. Penrose presented to the section a useful method of gauze drainage for the abdomen, which he had largely used during last winter, in at least thirty-five cases. He referred to the fact that the coils of intestine and the peritoneal surfaces adhere to the gauze and make it difficult to remove without the expenditure of an unjustifiable amount of force. His idea is to enclose the gauze drain in a thin rubber tubing made by cutting off the end of a rubber condom which is then slipped over the gauze and covers it where it comes in contact with the tissues, except at the extremity where the adhesions will be of little consequence. He had found it work very well in practice. Dr. B. C. Hirst, Chairman of the Section, read a paper on "Serum Therapy of Puerperal Septicemia." He had collected some thirty cases from current literature in which this method had been adopted. The serum employed was the anti-streptococcal toxin made in the Pasteur Laboratory in Paris by Marmorek, which he considered the best obtainable; he had no confidence in any form of anti-streptococcal serum made in this country which had been brought to his notice thus far. In the list of thirty cases, all of which had been treated by the Marmorek serum, there had been a mortality of 50 per cent., while the ordinary mortality of puerperal septicemia is only 25 per cent. Two patients, he declared, were evidently killed by the treatment, as their temperature record indicated that they would probably have recovered of their puerperal infection if the injections had not been given. Dr. Hirst further criticized the serum treatment by the anti-streptococcus serum by the statement that this at best was only claimed to be of use in streptococcus infection, but only 84 per cent. of clinical cases are of this character, the other 16 per cent. being distinctly something else, such as the staphylococcus pyocyaneus and ceruleus, pneumococcus, and so on. He had recently opened a large abscess after childbirth and had found it to contain only the pneumococcus. He therefore condemned the serum-therapy of puerperal septicemia as being not only inefficient but capable in itself of causing the death of patients who otherwise would recover. He believed that a more promising method of treatment was one which increased the number of white blood cells, causing a hyperleucocytosis, and referred to a recent paper in the *Centralblatt für Gynäkologie*, in which seven cases had been treated by this new method with very successful results.

THE PUBLIC SERVICES.

Army Changes. Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from May 16 to May 22, 1896.

Capt. Richard W. Johnson, Asst. Surgeon, granted leave of absence for thirty days, to take effect about May 11, 1896.
Lieut.-Col. William E. Waters, Deputy Surgeon-General, granted leave of absence for two months, to take effect on or about July 1, 1896.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending May 16, 1896.

Asst. Surgeon H. D. Wilson, ordered to examination preliminary to promotion.

Asst. Surgeon C. M. De Valin, detached from the Philadelphia Hospital and ordered to hospital at Chelsea.

Asst. Surgeon E. M. Shipp, detached from the U. S. R. S. "Vermont," and to the U. S. S. "Monongahela."

Marine-Hospital Changes. Official list of changes of station, and duties of Medical Officers of the U. S. Marine-Hospital Service, for the fifteen days ended May 15, 1896.

Surgeon R. D. Murray, to inspect quarantine ports on Gulf Coast of Florida west of and including Apalachicola and the coasts of Alabama and Mississippi, May 1, 1896.

Surgeon P. H. Ballhache, to inspect quarantine ports on the coasts of Connecticut, New York and New Jersey, as far south as Sandy Hook, May 1, 1896.

Surgeon George Purviance, to inspect quarantine ports on coast of New Jersey south of Sandy Hook and on Delaware bay and river, May 1, 1896.

Surgeon H. W. Sawtelle, to inspect quarantine ports on the coasts of Louisiana and Texas, May 1, 1896.

Surgeon H. W. Austin, to inspect quarantine ports from northern port of Maine, to entrance northern port of Rhode Island, May 1, 1896.

Surgeon George W. Stoner, to inspect local quarantine station at Baltimore, Md., May 1, 1896.

Surgeon John Godfrey, to inspect quarantine ports on the coast of California, May 1, 1896.

Surgeon H. K. Carter, to inspect Cape Charles Quarantine Station, and quarantine stations at Newport News, Norfolk and Richmond, Va., and quarantine ports on the coasts of North and South Carolina, Georgia, Florida and the coast east of Apalachicola, excluding Key West, May 1, 1896.

P. A. Surgeon C. T. Peckham, to inspect quarantine ports on the coast of Washington exclusive of ports on the Columbia river, May 1, 1896. Granted leave of absence for thirty days on account of sickness, May 15, 1896.

P. A. Surgeon Eugene Wasdin, granted leave of absence for two days, from May 14 to 16, 1896.

P. A. Surgeon G. M. Guiteras, to inspect local quarantine station at Key West, Fla., May 1, 1896.

P. A. Surgeon J. C. Perry, to inspect quarantine ports on the coast of Oregon and the Columbia river, May 1, 1896.

Asst. Surgeon E. K. Sprague, to proceed from Mobile, Ala., to Boston, Mass., for duty, May 1, 1896. To defer departure for Boston, Mass., until return of Surgeon Murray, May 6, 1896.

Asst. Surgeon H. S. Cumming, to proceed to Norfolk, Va., for temporary duty, May 12, 1896.

Asst. Surgeon H. S. Mathewson, when relieved at Boston, Mass., to proceed to San Francisco, Cal., for duty, May 1, 1896.

Change of Address.

Ashmead, A. S., from Norristown, Pa., to 210 W. 4th Street, New York, N. Y.

Adams, S. S., from 1632 K Street, N. W., to 1 Du Pont Circle, Washington, D. C.

Brown, H. M., from Hillsboro, to 2362 South Elm Street, Walnut Hills, Cincinnati, Ohio.

Burr, Albert H., from 163 State Street to Room 1106 Reliance Building, Chicago, Ill.

Eaton, R. K., from Lowell to Ithica, Mich.

Egan, F. A., from 451 Faye Street to 510 Graceland Avenue, Chicago, Ill.

Grote, H. W., from Hyde Park Hotel to 40th Street and Cottage Grove Avenue, Chicago, Ill.

Gregory, J. H., from Chicago to Cave-In-Rock, Ill.

Harding, Geo. W., from Chicago, Ill. to Twelve Mile, Ind.

Hogan, D. D., from Chicago, Ill. to Arena, Wis.

Hardesty, T. O., from Chantilly, Mo. to Kampsville, Ill.

Ketcham, L. Y., from 1535 2nd Street to 6th Street and University Avenue, San Diego, Cal.

Knight, F. C., from Libertyville to Waukegan, Ill.

Kinyoun, J. J., from 210 New Jersey Avenue to Marine Hospital, S. E., Washington, D. C.

Krusemark, Charles, from 125 to 94 E. 22d Street, Chicago, Ill.

McNary, H. F., from Princeton to care Central Insane Asylum, Lakeland, Ky.

Partell, E. J., from 146 Huron Street to 157 Michigan Street, Milwaukee, Wis.

Robinson, L. A., from Chicago to Glenwood Springs, Colo.

Schram, A. W., from Chicago, Ill., to 200 24th St., Milwaukee, Wis.

Turek, F. B., from corner Clark and North Avenue to 555 Dearborn Avenue, Chicago.

Wood, E. S., from 628 Jackson Boulevard to 524 Michigan Avenue, Chicago.

Washburn, W. H., from 803 to 726 Grand Avenue, Milwaukee, Wis.

ORIGINAL ARTICLES.

SURGICAL STERILIZATION AND STERILIZERS IN PRIVATE PRACTICE.

Read by title in the Section on Surgery and Anatomy, at Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 7-10, 1896.

BY EDUARD BOECKMANN, M.D.

ST. PAUL, MINN.

Last May I delivered an address in Buffalo, N. Y., before the "Association of Military Surgeons" of the United States, on "Asepsis in Military Service." This address printed in the transactions of that society and also in our own JOURNAL, Nos. 4 and 5, Vol. 26 (January 25 and February 1, 1896), considers at length the principles of sterilization, and gives at the same time a number of practical points just as applicable in operations in private practice as in operations in military service, for which reason I take the liberty to refer you to that for details.

With regard to the mechanical and chemic phases of surgical sterilization I have not much to add to or take from what I said last year. Supported by further experience I can this year more strongly than last recommend the 1 to 2 per cent. solutions of lysol at 120 degrees F. for combined mechanical and chemic disinfection of the operator's hands and the patient's skin.

Lysol possesses the undeniable advantage of being at the same time antiseptic and aseptic; it is a happy combination of a powerful disinfectant and soap (saponified cresol). It has the dissolving and penetrating properties of an alkali substance. I know of no agent which at the present time is better adapted and more reliable in the disinfection of the skin than lysol, with the possible exception of alcohol, which certainly, with good reason, receives the support of the world. Heretofore we have viewed alcohol in the light of a purely mechanical agent in the disinfection of the skin; this can no longer be successfully maintained. Alcohol is certainly a potent solvent of a great number of substances, sparingly however of fats. Alcohol must be viewed as a strong antiseptic, possessing the same significance for the skin as for anatomic preparations, taking up its moisture, penetrating and hardening them; a decided advantage over ether and turpentine, which certainly dissolve fat much more readily but which are much less hydrophile. In order to obtain the greatest possible antiseptic effects of alcohol it is obvious that the skin must be dried, and strong, preferably absolute alcohol used, and the skin energetically rubbed for some little time. Since experience has taught me that the germicidal principle in lysol acts as a powerful antiseptic in the above mentioned strength, and as a prolonged friction with absolute alcohol makes my skin uncomfortably hard and brittle, I reserve the alcohol for the field of operation only.

The last act in my sterilization of the skin consists in impregnating it with sterilized lanolin. By this procedure it is my intention to restore to the integument its fatty protective, which has been removed to the greatest possible extent by the preceding chemico-mechanical disinfection; at the same time I aim to cover up the remaining, inaccessible bacteria. Lanolin, which is rich in bacteria, is sterilized simply by heating the anhydrous article over the fire in an enameled vessel to about 350 degrees F., whereupon it is either run into collapsible tubes (sterilized in boiling water) or mixed with four to five parts of anhydrous ether, as soon as it has cooled below the boiling point of the latter, and then put into patent stoppered, sterilized glass bottles. Lanolin contains a great many impurities not soluble in ether, and which sink to the bottom as a voluminous, white sediment; only the clear, yellow solution is used.

Provided with lysol, absolute alcohol and ethereal solution of sterilized lanolin, we are enabled to disinfect the skin, the most dreaded bearer of infection, as safely, I imagine, as is possible at this time; and with as few and simple agents as can be demanded in operations in private practice.

While I practically occupy the same standpoint with regard to chemico-mechanical disinfection, I must take up the thread where I dropped it last year, as far as thermic disinfection is concerned. It is quite natural that surgeons who occupy themselves with operations in private practice, not only are interested in portable sterilizers, but also prefer such as are constructed for combined boiling in water and its steam. Inventive geniuses have also from time to time, at short intervals, endeavored to satisfy this popular demand, but they have all, as far as I know, up to the present committed the error of constructing their apparatus for under-steam, which streams through the sterilizing chamber from below upward; that is, a stream, which neither expels the air, nor penetrates the articles to perfection, and which consequently results in deficient condensation, besides leaving the articles moist. All sterilizers for streaming steam must necessarily be constructed for over-steam; the reasons being fully given in my article previously referred to. Personally I am not particularly in favor of combination sterilizers even when scientifically constructed, chiefly because boiling and steaming are different processes requiring an unequal time, steaming at least three times as long as boiling, not to speak of the time required to dry the dressings after sterilization. This entails the practical disadvantage, that instruments, for which boiling is our method of choice, suffer unnecessarily in the prolonged boiling but, as this can be avoided as I will explain shortly, I have in deference to the apparent popular demand revived the idea of a combination apparatus, which I described in the *Medical Record* a couple of years ago, and it is my improvement upon that apparatus which

I take the liberty to demonstrate upon this occasion.

My combination portable sterilizer consists, as you see, of four parts: 1. the boiling pan; 2. the hood; 3. the instrument tray, and 4. the steam chamber.

The boiling pan is made oval for the sake of the instruments; convenient dimensions being four to five inches high, eight inches wide and sixteen inches long. Around the upper border on its outside is constructed a groove half an inch deep. The center of the bottom is perforated by a small opening, into which is fastened a tube, which extends to the level

FIGURE 1.

of the upper border of the pan; under the opening at the bottom is placed the iron plate, familiar from my other sterilizers.

The hood, which fits closely within the outer lip of the groove of the boiling pan described above, and whose height is adjusted to that of the steam chamber, above which it extends half an inch, has a sloping roof, whose extreme top is perforated and fitted with a short tube or chimney. The hood is supplied with handles and can be fastened to the boiling pan by means of two hooks.

FIGURE 2.

The instrument tray is made to fit accurately within the boiling pan, the corners are cut off to allow for the legs of the steam chamber, the bottom is of galvanized wire and the frame is provided with two handles.

The steam chamber is of the same form and dimensions as the boiling pan: the chamber extends downward in a sloping bottom, whose lowest, perforated point is on a level with the upper border of the pan; into this opening is fastened a tube, which fits accurately outside that described in the boiling pan and

FIGURE 3.

which is of the same length; at the juncture of the steam chamber and its sloping bottom is placed a diaphragm of galvanized iron; between this and the opening beneath is a small square tin plate; the chamber rests upon four legs, is provided with handles and a sloping cover, perforated at the top underneath a handle.

Directions for use. The boiling pan is filled with a sufficient quantity of water, care being taken to fill

the groove at the same time; the hood is adjusted, and the whole placed over any good fire. While the water is heating, the instruments are arranged on the tray, and the dressings, etc. (previously washed) in the steam chamber; needles, drainage tubes, ligating and suturing materials are put separately in a small metal box (sterile catgut is brought along in hermetically sealed envelopes). When the water boils, the hood is removed, the steam chamber put in, whereupon the hood is replaced with a cork in the upper tube. The steam will now ascend between the hood and the steam chamber to the top; the cork at the top and the water in the groove and in the pan acting as locks, the steam is forced to work its way through the opening in the cover of the steam chamber into

FIGURE 4.

this, through the articles contained, and out through the tube in the boiling pan. In the course of a quarter of an hour the sterilization is completed; the hood is removed, also the steam chamber; the instrument tray is now put in, the steam chamber is replaced, the hood likewise, *but without its cork*. For the preservation of the instruments a little soda or soap has been added (lysol serves the same purpose). In the course of five minutes the instruments are surgically sterile; during this time the steam will escape continuously through the open tube of the hood, both that delivered by the water and that contained in the steam chamber: simultaneously a draught of hot air will enter the chamber from below and when this is

FIGURE 5.

removed, its contents are not only sterilized but also dry. A combined sterilizer of the dimensions above mentioned can without difficulty be transported in a suitable wooden case and as the preparation and sterilization of the necessities is an easy matter, there is no possible excuse for resorting to mercantile antiseptic goods in operations in private practice. The surgeon who relies indiscriminately upon antiseptic wares, which he buys, is a dangerous man!

Articles adapted to sterilization by steam can safely be transported to the place of operation in various ways. Bloch's method in double filtering paper being preferable; it is, however, always safer to sterilize on

the spot, and, as only half an hour is required for the whole procedure, it is also practicable. In urgent emergency cases a surgeon ought never to be taken by surprise and as time is valuable in such cases he should always have on hand a supply of sterilized articles.

One more remark with regard to operations in private practice; I will most emphatically impress upon all surgeons, with the possible exception of those few, who are masters both in surgical technique and in asepsis, to consider every wound at the end of an operation of some duration as slightly infected, and therefore to combine their asepsis with a judicial antiseptis. Thus I am in the habit of repeatedly dipping my hands during the operation in a weak, sterile solution of lysol ($\frac{1}{2}$ per cent. or even less). The small amount of antiseptic which in this way is carried into the wound, I have yet failed to find objectionable, and I use lysol, because it is at hand, and because it is alkaline like the fluids of the tissues. And when the operation is completed, I apply next to the wound an antiseptic dressing not exactly the customary iodoform gauze, because its preparation requires extraordinary facilities, but antiseptic and at the same time aseptic, hydrophilic ointments. Anhydrous lanolin absorbs moisture greedily; it is first sterilized, mixed while cooling with 2 per cent. lysol and run into tubes. A generous quantity is expressed over the wound, and over this the ordinary dressing is applied. Changing this dressing is unattended by the disturbance of the wound or the patient's comfort, as it does not stick like a dry dressing.

In the foregoing it has been my aim to dwell upon the most essential points in surgical sterilization and sterilizers in private practice, points, which I could stamp with some degree of originality.

SOME MECHANICAL CAUSES OF INTERFERENCE WITH THE ACTION OF THE STOMACH AND THEIR SURGICAL RELIEF.

Read in the Section on Surgery and Anatomy, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY W. J. MAYO, M.D.

SURGEON ST. MARY'S HOSPITAL, ROCHESTER, MINN.

Mechanical interference with the action of the stomach naturally divides itself into two classes: 1, those which act from within the cavity of the stomach or its immediate connections, such as a tumor, cicatrix or a foreign body which may obstruct its inlet, outlet or prevent its normal muscular action; 2, those which act from without the stomach and interfere either by pressure or adhesions, obstructing its inlet or outlet or fixing some portion of its wall, thus preventing its functions.

Methods of diagnosis: For practical purposes the history, the physical examination, the distension with air and the test meal, constitute our main diagnostic resources. A careful history includes the early symptoms, pain, tumor or swelling, vomiting with its character, and such other evidences as suggest themselves. The distention of the stomach with air to facilitate mapping out its outline is an exceedingly important factor in the diagnosis. With an ordinary stomach tube and a valve syringe of the enema pattern, air can be easily and safely pumped into the stomach and it readily escapes upon disconnecting

the syringe. The test meal is of importance in the diagnosis of cancer. From a considerable experience I feel sure that the slight or non-presence of free hydrochloric acid is of some service, in the differentiation of chronic obstruction due to cancer, when taken into consideration with the physical examination and history, although of itself having corroborative value only. Many new methods of examination of the stomach have been reported. The use of a small electric light to illuminate the gastric cavity, also complicated apparatus for the purpose of reflecting or measuring the interior of the stomach, etc. All of these have little value to the practical surgeon at the present time, although possibly of future usefulness. The examination of the urine for the finding of certain products supposed to be indicative of cancer is interesting, rather than important.

Mechanical obstructions of the cardiac orifice of the stomach or the esophagus are most commonly due to malignant disease or the cicatrization following upon the action of caustics; more rarely to aneurysms or tumor pressure from without. The diagnosis of the location of the obstruction by means of esophageal bougies is easy and needs no comment, while the history and rational signs and symptoms point to the pathologic nature of the obstruction.

The treatment of those forms due to stenosis as a result of scar tissue is exceedingly trying. Some of the less resistant ones when seen early can be dilated by means of bougies used through the mouth, but after failure of catheterization in the usual manner the opportunity of more direct manipulations afforded by external esophagotomy has been pointed out by Sonnenburg, and should be borne in mind. In two out of three cases of cicatricial stenosis of the esophagus of my own this was well illustrated. One a male aged four, in which I was unable to pass a probe through the mouth, yet succeeded through the external esophageal incision. If unable to pass a bougie, retrograde dilatation by means of gastrotomy, is a rational procedure and with the string method of dividing the stricture introduced by Abbe, which I have used in two reported cases, enables us to deal with otherwise hopeless conditions. In the gradual dilatation which is so necessary in the successful after-care of these sufferers, I have found the olive tipped whalebone bougies the ones of most value and after the treatment is well advanced, the use of probes having several graduated bulbs on one stem as recommended by Solis-Cohen, is of great service.

Gastrotomy for the purpose of retrograde dilatation, is perhaps best done by Fenger's oblique left lateral incision through the abdominal wall, which brings this opening more directly in line with the cardiac orifice. For work on the pylorus or the removal of foreign bodies or gastric exploration, generally, the central incision above the umbilicus has many advantages.

Gastrotomy for the removal of foreign bodies, accidentally or purposely swallowed, or slowly collected such as hair balls, is an operation of great efficiency. Much credit is due Maurice H. Richardson for his work in this field.

Gastrostomy for the purpose of feeding necessitated by cardiac or esophageal obstruction when done by Fenger's method is subject to great annoyance in the way of leakage. This was particularly marked in a case under my care. Fortunately for the comfort of the little patient the purpose of the opening was

shortly obviated by relief of the obstruction. The necessity of repeated attempts to penetrate the strictured portion of the lower esophagus as well as for feeding purposes, made Fenger's operation, in this case, the only one available.

Other methods of operation while giving better closure, would equally prevent ready access to the cardiac orifice. Both the Witzel method and that of Frank are free from this annoyance and for temporary purposes the Witzel method is of the greatest benefit, as immediately after removing the tube the fistulous tract closes at once. In one instance in which I operated by this method this was so well marked that the accidental slipping out of the tube was followed in a few hours by great difficulty in reinsertion. Frank's spout method as it requires no tube is undoubtedly the best for permanent feeding, and as it is an operation which can be speedily performed it readily classes with the Witzel as far superior to that of Hahn, Van Hacker or Fenger in preventing leakage.

Obstructions at the outlet of the stomach are exceedingly common and too often pronounced malignant, without proper examination. This is especially true of the pyloric stenosis secondary to ulcer, and as even a tumor may be found, in the latter condition due to the peritoneal thickening over the cicatricial area, much care should be given in the diagnosis to determine the nature of the obstruction. The history of long previous ulceration with the presence of free hydrochloric acid and its slower course are among the readier means of differentiation and it should also be borne in mind that a non-malignant polypoid or valve acting tumor, at the pyloric orifice, may be the cause of the obstructive symptoms as well as a cancerous growth. For the relief of non-malignant stricture at the pylorus, Lorretta's method of divulsion is open to the objection of strong probability of recontraction, so common in other strictured mucous passages, such as the urethra.

The Hoenke-Mukuelitz pyloroplasty operation is the one of choice and is wonderfully well adapted to the average case. For example, I will briefly report the following case: M. M., age 46, has suffered from severe and painful gastric symptoms for seven years, for which he has been treated almost constantly, obstructive symptoms gradually becoming more prominent, and for the past eighteen months, he has daily vomited almost the entire amount of food taken and has lost eighty pounds in weight. Just above the umbilicus a small tumor could be felt, which was more or less movable and on dilating the stomach with air this mass moved to the right and upward, while the air-dilated stomach filled almost the whole abdominal cavity. By making pressure on the dilated stomach and listening with a stethoscope over the enlargement, a hissing of gas passing through a fine orifice could be heard. Test meals showed the stomach contents to contain free acid. Celiotomy showed, as expected, a cicatricial obstruction of the pylorus due to former ulceration. Pyloroplasty was readily performed, and as the patient took the anesthetic badly he was allowed to come out from under its influence and complained of no pain during the introduction of the Czerny-Lembert sutures in the stomach wall but required further anesthesia in closing the external incision. This lack of sensitiveness in the visceral peritoneum has been pointed out by Greig Smith. His recovery was prompt and the gain in weight remarkable.

For inoperable obstruction such as advanced malignant disease, gastroenterostomy is the operation of choice. Anastomosis by means of bone plates inaugurated by the master surgeon, Senn first popularized this operation, may however be open to the objection of too small an opening with too large a coapting surface for future contraction. The suture method is slow with danger of leakage and as the average patient is only too frequently at the point of collapse, from chronic starvation, the Murphy button even with the disadvantage of its possible passage backward into the stomach rather than onward into the intestine, is a quick and safe method. I have employed the button in three gastroenterostomies with two successes and one death, and in the latter case the union was perfect, although the patient on the verge of collapse from starvation due to advanced malignant obstruction succumbed to exhaustion on the fifth day. Of the two that recovered one is alive and well with a gain of forty pounds in weight at the present time, one and one-half years after the operation. This case was suffering from acute starvation and his condition would not warrant a pylorotomy, which a tumor of unknown nature indicated. In making a gastroenterostomy the jejunum should be caught at its origin and a loop formed with the direction of its peristalsis in the same direction as the stomach to prevent impaction of the upper portion, or as Kocher recommends, transversely to the axis of the stomach, thus allowing gravity to aid the passage of the food in the proper direction. The curetting of gastric cancer through a gastrotomy wound as advocated by Bernays has little to recommend it. Pylorotomy is but infrequently done. Its frightful mortality in malignant disease without reported permanent cures is not encouraging. The reason for this great mortality lies in the debilitated and starved condition of the patient at the time operation is resorted to, although Kocher has recently reported five primary recoveries out of seven pylorotomies. In the case previously referred to of tumor of doubtful nature obstructing the pylorus in which I joined the stomach and jejunum with Murphy's device, it was my intention to wait until the patient was in better physical condition as a result of the gastroenterostomy and then at a secondary operation resect the pylorus and close completely the end of the duodenum and the stomach utilizing permanently the existing fistula. He received so much relief from the first operation that he declined to submit to any further interference. I fully believe that preliminary gastroenterostomy would put the patient in much better condition for the major operation and by allowing permanent closure of both duodenum and stomach at the points of section would largely reduce the mortality. In any case it is better, as pointed out by Bull, to carry the gastric opening well away from the dangerous suture line.

Brandt has treated dilatation of the stomach caused by chronic catarrh, by plecting its anterior wall with a Lembert suture and he reports great benefit from this procedure, the object being to relieve the dependent portion allowing gravity to aid the gastric contents to work toward the pylorus. Cases of chronic dilatation of this character are usually due to some form of pyloric obstruction and this operation is therefore rarely indicated.

Interference with the stomach from without its cavity: Among the external causes of interference with the stomach, adhesion of the pylorus or duode-

num to the gall bladder due to the inflammation excited by gallstone, is not infrequent. In some thirty operations for gallstones, I have seen at least three cases in which the colics were infrequent but in which the gastric distress was constant and found to be caused by such adhesions, and relief was undoubtedly due more to the liberation of the adherent viscus than to the removal of the stones.

Adherent omentum: The most common cause of external interference with the action of the stomach is the fixation of some portion of the omentum in a hernial ring producing traction upon the stomach, and of these incarcerated omental hernias, the least often recognized are the button-like protrusions through little defects in the median line above the umbilicus. I have operated upon a small number of such cases with marked relief to gastric symptoms.

Irreducible omental hernia of any variety, are almost always accompanied by gastric distress and it is the rule that this disappears after the radical cure of the hernia. Not only do omental adhesions cause distress but they may fix or distort the stomach to an astonishing extent without symptoms directing attention to the hernial protrusions. In one instance a male, 54 years of age, had suffered for seventeen years from gastric pain and chronic indigestion. Test meals showed free acid. On dilating the stomach with air it was found to expand in a remarkable degree downward and to the right; careful examination revealed an old irreducible omental hernia of small size on the right side, which he had had for years. Radical operation on the hernia with liberation of the omentum promptly relieved the symptoms. These cases are common. Chronic gastric distress following abdominal operation is not infrequently due to post operative adhesions of bruised or ligated omentum and may necessitate secondary operation for their liberation.

DISCUSSION.

DR. ALEX. HUGH FERGUSON, Chicago—There are some very interesting points in this paper and it is a very clear representation of the surgery of obstruction of the esophageal and pyloric ends of the stomach, both by disease of those regions or by external violence. I do not think that I have ever heard of so much condensed into a paper, occupying but fifteen minutes to read, and I congratulate the author upon the mature opinions expressed and the manner in which he states the case. I fully agree with him in his opinion of treating non-malignant and malignant stricture of the esophageal end of the stomach and with the palliative treatment that he recommends for malignant disease of this region, discarding curettement and recommending Frank's operation as superior to Witzel's and Fenger's. This is certainly the proper operation and will give the patient considerable comfort, but it is only palliative. We are sorry that some radical means of extirpating the cancer can not be discovered, but disease in this locality, where the vessels are so closely approximated, is extremely hard to get at and a radical operation is a difficult question. Now we come to the pyloric end of the stomach, and I agree with the Doctor in his remarks about forcible dilatation. In preference to this, I believe the best operation is a pyloroplasty, making a longitudinal incision and enlarging the opening if necessary. That part of the paper was very interesting. Next to this comes gastroenterostomy which is a recognized operation. Dilatation in pyloric disease of the stomach can be done in several ways. Gastroenterostomy can be done in two classes of cases, first, those that are weakened and could not stand pyloroplasty, and secondly, where it is expected to be cured palliatively. It may also be done as a preliminary step of the complete removal of the pylorus. If the disease is well limited, I see no reason why the pylorus should not be removed. The Doctor spoke of cases of pylorotomy performed in America, eight of which have died and five recovered; of this eight six died from shock, one from imperfect suturing and one from a sponge being left in the stomach. I believe in encouraging pylorotomy for several reasons, not that I do not fully realize

the gravity of the operation and not that I am not aware of the mortality that follows. Supposing we have a diseased condition that is hopeless for any other form of treatment. The medical treatment for cancer of the pylorus has a mortality of 100 per cent., which is as much as any one could wish for; therefore if you can do a pylorotomy, it would be preferable to the palliative means. Pylorotomy permits of cure within certain limits, first when we know that the cancer is limited to the pyloric end of the stomach. Of over 900 cases reported, in 19 per cent. of them the disease did not reach the peritoneum. In 19 per cent. the patients died of starvation when the disease had not extended to all the coats of the stomach. We know from the same report that 43.7 per cent. of deaths take place while the disease is still local, that is before it has gone into the lymphatics and while the pylorus is movable. We know too from the same report that about 50 per cent. of them recover from the operation of pylorotomy, and a great many of the cases that have been operated upon have not been proper cases for operation as the disease has been too extensive. The ultimate result of pylorotomy, although not so very encouraging, is more encouraging than is the operation of gastroenterostomy. Some cases after this operation have run on for years. I know of one case which went on for three years and is to-day able to work on a farm. I agree with Dr. Senn in the remarks I heard him make this afternoon and also in those I have heard him make before. In order to have an indication for performing pylorotomy, we must have the disease limited and our patients not too much weakened by starvation. When we suggest operation in such a case, making sure that the patient can stand it, a pylorotomy is the rational and reasonable one to perform. We all know that it used to be taught that cancer of the breast was not a justifiable operation, but we know better now.

DR. DONALD MACLEAN, Detroit—I listened to Dr. Mayo's paper last night with about the same kind of pleasure that a father listens to a good epoch on the part of his son, as that is about the relationship which exists between Dr. Mayo and myself. I have had the pleasure of watching him develop from a green Western boy to one of the ablest of the younger American surgeons. So far as this paper is concerned, I agree with the other members of this section who had the pleasure of listening to it last night. As far as the treatment of gastric surgery is concerned, it would be out of place for me to undertake to discuss it to any extent, as it does not come in my way to do this kind of surgery. I have dabbled in surgery in various parts of the body for many years, and I have a firmly grounded belief that if the actual statistics of cases of operative interference for diseases of the stomach were put before us, it would be rather humiliating. I believe that a good number of operations are performed in cases in which, as a matter of fact, the patient should have the privilege of dying without any assistance from surgeons. I would be the last man to discuss any legitimate and proper effort to prolong life where there is a chance of doing so. Dr. Mayo's views on the subject are of a decidedly conservative nature and he does not advocate operating because the patient would die anyway. This, I consider a very poor argument and does not redound to the benefit of the patient or the honor of the surgeon. When surgical interference is decided upon in cases of organic disease of the stomach, my view is that it should be done after a most careful examination and because it holds the prospect of relieving the patient of suffering and prolonging the life. I think we, as the Section on Surgery, should record our belief that this is the proper doctrine and the proper idea to go upon.

DR. MAYO in closing the discussion said he did not wish to take up the time of the Section any further.

LIGATION OF EXTERNAL CAROTID ARTERY IN CONJUNCTION WITH EXSECTION OF JAWS, AND THE INOPERABLE DISEASES OF THE SAME.

Read in the Section on Surgery and Anatomy, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY WILLIAM PERRIN NICOLSON, M.D.

PROFESSOR OF ANATOMY AND LECTURER ON CLINICAL SURGERY,
SOUTHERN MEDICAL COLLEGE,
ATLANTA, GA.

A survey of the literature of surgery will demonstrate the fact, that of all the great vessels that we have dealt with, the external carotid has been less frequently subjected to ligation than any other, if we except its companion the internal. This has largely

due to the fact, that prior to the advent of the present era of surgery, the anatomic distribution of the branches of this vessel acted as a bar to its closure, on account of the danger of secondary hemorrhage at the time of the separation of the ligature. Since the advent of the antiseptic practice, which has rendered it safe to leave a ligature *in situ* without fear, this has ceased to be an objection, and this vessel has become one of those most accessible, and whose ligation is practically free from subsequent danger. When we consider its territory of distribution, and the structures supplied by it, we can well understand that a wide field of usefulness has been opened up by our ability to control the circulation through its various branches. We are thus enabled to cut off the blood supply from one, or both, sides of the head and face, as may be necessary, without interfering with the cerebral circulation; and without producing an anemia of any vital structures.

Reasoning along this line, six years ago I made use of this operation as preliminary to, and co-incident with, the removal of the upper jaw, and a further experience has confirmed all that I hoped to accomplish by it. After an experience of four operations in the removal of the upper jaw, and one of the lower jaw, I am convinced that the following facts can be claimed for the operation:

1. It absolutely prevents danger from hemorrhage, which, though not usually great, has been known to prove fatal in the hands of the best operators.

2. Shock is thus largely prevented.

3. The time of the combined operations is in most cases no greater, if not less, than that required for extirpation alone.

4. The return of the growth, when malignant, is materially lessened, if it may not be prevented.

As illustrating the application of the operation, with its immediate and remote results, I beg to submit the following cases:

Case 1.—Mrs. A., white, age 40, consulted me for tumor of the right upper jaw of about one year's duration. The occurrence of pregnancy had materially hastened its growth, and I was called to see her about the eighth month, with an urgent request for operation. At this time there was a development of the tumor pressing down the hard palate, preventing closing of the jaws, and seriously interfering with her nourishment. Not feeling that the condition was sufficiently urgent, I declined to operate until the completion of her pregnancy. On May 21, 1890, seven days after her delivery, the patient was transferred from the parturient bed to the operating table, and the operation performed with the assistance of Drs. Elkin, Purse and Stewart. The external carotid was ligated between the superior thyroid and lingual branches with catgut, and the wound closed with catgut sutures. On account of the deep neck, and enlarged veins, this was an operation of some difficulty, and occupied more time than has been required in any subsequent operation. The jaw was then removed without tying a single vessel, though there was profuse venous oozing during a part of the operation. The wound was closed with catgut, with the exception of that through the upper lip, which was closed with silk. Primary union occurred, and within two weeks the cavity was closed. The cancerous cachexia was quickly relieved, and the patient rapidly restored to robust health, which lasted more than one year. About the thirteenth month there was a recurrence which shortly ended her life.

Case 2.—Sarcoma of the upper jaw. Emeline H., colored, female, 64. Enlargement in the upper jaw about two years ago, and progressed slowly until a few months since, when it took on a very rapid growth. When seen by me there was a very large tumor, projecting forward in its principal line of growth, and also pressing down the hard palate, and filling up the mouth. The operation was performed at the Grady Hospital on March 8, 1894, with the assistance of the resident staff of the Hospital. The external carotid was tied immediately in the bifurcation with catgut, and the neck wound closed by

deep and superficial catgut sutures. The patient did excellently well, and at the end of six days the wounds were all healed; when she was seized with a stroke of cerebral apoplexy, and died the following day.

Case 3.—Mrs. J., age 54, white, brought to me by Drs. Crawford and Henley, of Abbeville, Ga., with the following history: Six months before she suffered from an abscess of the antrum, which was opened through the socket of the molar tooth, and treated in the usual manner. The abscess refused to heal, and in a short time the bone began to enlarge. This enlargement continuing, a diagnosis of necrosis was made, and a point opened for purpose of drainage and removing some bone, but there was very little discharge. When I saw her there was a large tumor apparently pointing through the center of the cheek, the skin adhering over its entire center. Yielding to the view that there might be possibly some necrosis, the case was held in suspension for a few weeks, though I expressed the opinion that it was a sarcoma. At the end of this time, on account of the rapid continuation of the growth, there was no doubt as to the diagnosis. Operation was performed Jan. 5, 1895, at the Grady Hospital. The external carotid artery was tied as in the other cases immediately in the bifurcation and wound was closed in a similar manner. In attempting to remove the jaw it was found that the adherence of the skin rendered it necessary to leave quite a circular opening in the center of the flap. The entire jaw was removed, including a complete removal of the floor of the orbit. The wound in the neck was dressed with a strip of iodoform gauze and collodion. The healing of the face was complicated by the opening, which was left to granulation, and by the peculiar and persistent edema of both upper and lower lids, requiring the puncture every other day for the purpose of removing the serum. I know of no condition that will illustrate the appearance of the lids better than the large effusion sometimes seen in the prepuce. This condition continued for a number of months, but finally disappeared. The wound in the neck healed under one dressing, and on the eighth day the iodoform gauze scab was removed, showing complete union. Though this was a most malignant case, the patient at this time is enjoying perfect health, sixteen months after operation.

Case 4.—Eliza N., colored, aged 30. This patient was seen at the clinic of the Southern Medical College in November, 1895. Large tumor of the upper jaw beginning four years ago, taking on rapid growth within the last few months, presenting the typical appearance of a sarcoma. The patient was operated upon at the surgical clinic Nov. 25, 1895, with the assistance of Dr. Elkin and the corps of students. The external carotid was tied with catgut in the bifurcation; the wound closed as in the last case with iodoform gauze scab, and the upper jaw removed without ligation of any vessel. Time of carotid ligation fifteen minutes—entire operation forty minutes. Patient made rapid recovery, the neck wound closing under first dressing, iodoform scab being removed on the seventh day; discharged from treatment two weeks after operation. History since that time is not known.

Case 5.—Emma H., colored, age 18, with the following history: Right side of the lower jaw beginning to enlarge about eight months ago. This enlargement has been continuous until the present time; has a tumor the size of a small orange, extending from just in front of the angle of the jaw, forward to near the symphysis. Diagnosis sarcoma. Operation at the Southern Medical College clinic Dec. 10, 1894, assisted by Drs. Elkin, Hurt and Davis. External carotid was tied in the bifurcation as in preceding cases. Wound closed with iodoform gauze and collodion. Right half of lower jaw removed from symphysis to articulation without ligating any vessel. Carotid wound healed under first dressing, scab being removed on the seventh day. The patient left for her home in Alabama twelve days after the operation, with all wounds healed. Up to this time there has been no recurrence of the disease. The time of the operation was forty minutes.

Case 6.—Illustrating the effect upon inoperable conditions produced by cutting off blood supply, the following two cases are reported: W. C. J., white, male, arrived at the surgical clinic of the Southern Medical College in December, 1895, with a typical and rapidly growing sarcoma of the right upper jaw. It was designed to make a combined operation as in the previous cases, but when the patient was placed upon the table, it was found that the universal adherence of the skin to the entire tumor rendered its removal impracticable; so it was determined to ligate the external carotid artery, with a view of starving out its growth. The vessel was tied as in previous cases, and the wound closed with iodoform gauze scab. The patient made a rapid recovery, being confined to bed only three days. Previous to the operation the right eye had been closed entirely by the pressure of the growth for the past three

months, and the nose pushed over to the opposite side by its encroachment. At the end of seven days, when he left for his home, the tumor had receded sufficiently to permit a perfect opening of his eye, and it also receded from its pressure upon the nose. It was estimated by a casual observation, that the growth had lost within one week, fully one-third of its size. This patient has not been heard from since he was discharged from treatment.

Case 7.—Mrs. F., white, age 54, a patient of Dr. Vaughn, of Fairmont, Ga., consulted me in December, 1895, for an ulceration inside the right cheek. There was a history in this case of a small sore forming in the mouth about eight years previously and gradually extending, until at the time of consulting me it had extended from the last molar tooth forward to the angle of the mouth where its elevated surface could be seen projecting, making a typical cauliflower excrescence. There was also an enlargement of the lymphatic glands of the neck. The diagnosis of epithelioma was made and patient advised to have the external carotid ligated in order to cut off the supply of nutrition from the growth, as it was clearly impossible to remove the diseased tissues. On Dec. 10, 1895, assisted by Drs. L. B. Grandy and W. B. Vaughn, the external carotid artery was tied in the bifurcation as in the former cases. On account of fat neck and high division of the vessel, this was about the most difficult operation of the kind that I have ever encountered, it being necessary to tie the large trunk of the facial and lingual veins, as they crossed just below the bifurcation. The exuberant growth of the ulcer was curetted away and the cavity packed with iodoform gauze. Time of carotid ligation one hour. The patient recovered without any disagreeable symptoms, except a persistent cough and some peculiar hoarseness, which I attributed to some temporary injury of the pneumo-gastric nerve. She left the city on the eighth day of the operation, wound nicely healed and the ulcerated surface rapidly closing up. Reports from the patient's physician state that she is in perfect health since, and with the exception of a small spot, the ulceration has disappeared. She reports her health better than for five years.

These cases serve to illustrate that the ligation of the external carotid is not a dangerous or very difficult operation, but some points in connection with the work are worth mentioning, as little is said upon the subject in text-books. The incision should be from two to four inches long, according to the depth of the neck, though I believe it is better to begin with the former and extend it if necessary. With a thin neck and a normal division a two-inch incision is ample. The center in this incision should be at a point parallel with the "Adam's apple." After the skin and deep fascia have been passed, the work is largely done with the handle of the scalpel and finger. In this way the vessel can be rapidly approached without danger. The chief obstacle to be encountered is the crossing of the vessel by the facial, lingual and superior thyroid veins, their combined trunks making, in some cases, an enormous vessel. These can be pulled aside when the division is at the normal point, but sometimes they must be cut between forceps and tied. The ends should be tied at once, as in one of my cases the forceps were, in the confusion of some accident, removed, with the result of a fearful hemorrhage for a few minutes. In only three cases have I seen the internal jugular vein, and this was when the common carotid was followed up to the dividing point. When the artery is reached it should always be remembered that the external carotid is the nearer to the median line, and should any doubt still exist, the first branch given off will decide the issue, as the internal carotid does not give off branches in the neck. In one case in which I operated the external carotid lay immediately above the internal. In the cases reported the point of division varied, in several cases being as much as an inch too high; it has never been too low. In my opinion this decides the difficulty of the operation; a high division, especially when combined with a deep neck, making a difficult one.

The point of ligation in my cases has varied somewhat. In the first case I tied the vessel above the inferior thyroid, though I did not tie any adjacent branches. This is unnecessary. In the last six cases I have placed the ligature immediately in the bifurcation, and below the superior thyroid branch. In preparing for the introduction of the aneurysm needle between the trunks it should be remembered that they are always bound together by a very tough areolar tissue.

As regards the material for ligature and sutures, as reported in these cases, I have used catgut, and making what is known as the "Ballance and Edmonds" knot. In the last six cases the only dressing applied by me has been the iodoform and collodion scab, and in each of these instances union has occurred absolutely under the first dressing, not a single one requiring a second dressing.

In conclusion I would say that in my opinion this class of work is now in its beginning, and that the future will demonstrate great benefits to be derived along the lines that I have set forth.

DISCUSSION.

DR. PARKER, New Orleans—My experience in ligation of the external carotid artery has been limited. I have seen it done several times for malignant growths. I was very much surprised at the length of time within which the growth diminished after ligation of the external carotid in Dr. Nicolson's case. The cases that I have seen have been where the anastomosis was so free that the rapidity of the growth was delayed but a short time. As to the knot to be employed I think the "Ballance and Edmonds" is the best. Lately I have employed kangaroo much more frequently than catgut. Another point mentioned by Dr. Nicolson was illustrated by a case I recently saw. When we come to ligate the external carotid artery and control hemorrhage in the removal of tumors of the superior or inferior maxilla, we should ligate the artery and remove the maxilla at once. I saw a case recently in which the external carotid had been ligated three days preliminary to removing the maxilla for a sarcoma. The hemorrhage was so free that I thought the patient would bleed to death on the table. If we are to ligate the carotid, we should do so at the same time that we remove the growth. I would like to hear the opinion of some of the gentlemen who have ligated the artery to prevent or delay a growth. In cases that I have seen it has not worked.

DR. EDMOND SOUCHON, New Orleans—There is a very important point in this paper which has not been touched, whether it be for a growth or for a hemorrhage, and that is the ligation of the two carotid arteries. I saw this operation performed once in New York for the removal of a very extensive sarcoma of the upper jaw. I notice in Dr. Nicolson's paper that sometimes the ligature was applied above the lingual artery. When the artery is ligated on one side, the location of the ligature is an easy matter, but when it is ligated on both sides, it is a question where we should ligate. It should be above the origin of the lingual artery and great care should be exercised in the use of the ligature. On account of the hemorrhage which may take place if the ligature is drawn too tight so that the coats of the artery are ruptured there is considerable risk and one should be very careful in order to avoid a secondary hemorrhage.

THE CHAIRMAN—I regret that Dr. Nicolson did not describe his incision. I am in favor of ligating the common carotid because it is easily gotten at. The gravity of the operation is not materially increased, but I do believe that the growth is delayed. I believe the collateral circulation is helped by ligating the common carotid.

DR. PARKER, New Orleans, said he had seen three or four cases in which both linguals were ligated for epithelioma of the tongue and in all of these cases the ligation did not seem to materially decrease the rapidity of the growth.

THE CHAIRMAN said there was a time when we thought that there was some prophylactic value in the ligation of these vessels, and unless such is the case, it seems to me that other operations are simpler and answer the purpose better.

DR. NICOLSON, in closing the discussion, said: As to Dr. Parker's remark concerning the lessening of the growth of the tumor, he can not be more surprised than I was, and I regret that I do not know how long this improvement continued. When I first him the man's eye was entirely closed by the

growth and the next week it was open. The anastomoses are so free and the blood supply so rapidly restored that I very much fear that this improvement did not last long. In reference to Dr. Souchon's remark about tying both carotids, I believe the time will come when the maxillæ will not be resected without tying both arteries. I performed an operation yesterday and intended to tie both arteries, but for fear that something might happen, I only ligated the one on the worst side of the neck. I did this on account of the lymphatic glands. When I reached around with my finger and brought up one of the glands, the external jugular vein came with it. The separation of this gland from the vein took some time and I had to discontinue after tying one vessel. I shall tie the external carotid on the other side within a few days if the patient will let me. In reference to ligating above the lingual, I could imagine nothing that would go further in preventing me from accomplishing what I want. To tie both arteries in the bifurcation is a good point. As seen in Dr. Parker's case, in three days the hemorrhage was so great as to require transfusion, and if one performs this operation expecting it to be a bloodless one, he will be very much surprised. The first time that I did the operation I was satisfied that I had tied the wrong artery. This extensive bleeding, however, can be quickly stopped by sponging, and I have never been called upon to apply ligatures in these cases. Healing has always been very complete. In reference to Dr. Souchon's remark about rupturing the coats of the artery, I was very much afraid to take up too much of the time of the Section and left out of my paper this and other points. I have been careful to avoid rupturing the coats, and always draw the ligatures until, placing my finger above, I find the circulation has been controlled. The knot I employ seems to be far more satisfactory than any others. (The author illustrated the "Ballance and Edmonds' knot.") In reference to the incision, one surgeon says one thing and one another. With a thin neck and the head drawn well back, all that is needed is a two inch incision. I was foolish enough to go around calling this a minor operation when I first performed it, but have since changed my mind, although I have completed it in less than ten minutes. The incision I have made has been parallel with the border of the sterno-cleido-mastoid muscle. When you get inside you can be guided largely by your finger. In my operation yesterday when I had my finger in position, I could perceive no pulsation. With the rapid breathing of the patient, feeling the pulsation is much easier to describe than to do. As to tying the common carotid, I dislike to take exception to this point. The claim of the external carotid over the common is its effect upon the superficial circulation. The mortality in the operation of tying the common carotid was 25 per cent., while that of the external is practically *nil*. Dr. Bryant, of New York, has done some work in this line and has said that the ligation of the common carotid when removing the upper jaw is unjustifiable. In a case where there is a malignant disease of the upper jaw, if on account of the glandular enlargement, it is impossible to reach it, I should not hesitate to put the patient to the risk of tying the common carotid.

VERDICTS OBTAINED THROUGH PERJURY.

Read at the Second Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Ill., Sept. 25-27, 1895.

BY C. B. KIBLER, M.D.

TREASURER AMERICAN ACADEMY OF RAILWAY SURGEONS, COREY, PA.

In presenting briefly a line of thought that might perchance be the means of bringing out a theme for discussion from the Fellows present, I present a subject that has not, to my knowledge, been even briefly presented before any body of railway surgeons, or before any medico-legal society up to this time. If such has been the case, I am free to say it has entirely escaped my observation.

It is barely possible that the theme lacks in interest, and perhaps is untenable. Yet it has occurred to me upon many occasions, when a claimant has procured a fat verdict from some innocent corporation, with the merits of the case built entirely upon air, together with the malingering symptoms set up by the claimant, prompted by the ever ready advice of his unscrupulous legal adviser, who perchance has taken the case on commission, or on the coöperative system,

that when the claimant has obtained his verdict and divided up the proceeds as best appeases the scruples of his attorney, which amount, by the way, is not always the lesser of the two halves, the astonishing rapidity with which the prosecutor regains his former good health prompts one to say that the verdict was rendered, not upon the true merits of the case, but that it depended and resulted from the unscrupulous testimony of plaintiff's apparent great suffering of pain, but strictly ephemeral in character, and from non-use, often showing atrophy of muscles.

With sympathetic friends as witnesses, who are quite prone to an elastic conception of the truth, at the same time quite forgetful of any important fact that might be at all advantageous to the defendant, and that ever-ready expert, who for a large consideration and statistics, might presumably be induced to so shape his views as to fortify the case against the corporation—with such an army, it is almost impossible for the sympathizing jury of twelve true and honest men to see any other way than to present a verdict which is supposed to be arrived at without bias, in such sum as will satisfy the claimant and make him comfortable for the balance of his natural life.

Corporations receive no respect or mercy at the hands of the ordinary jury of to-day. It matters but little how much merit or demerit any case for damages at the present time may possess. The usual result is quite probable to mulct the company for large damages.

Let it be clearly understood that no reference is here made to that class of cases in which corporations are honestly liable. This latter class almost invariably can be adjudicated through the proper claim department of any company, and generally with much better compensating results to the claimant than through the courts. It is to the malingering class I now wish to draw your attention.

It is true that it is often difficult to work out the wheat from the chaff in this line of cases, but when you see a claimant who has been so entirely incapacitated from the performance of any and all kinds of work appertaining to his vocation, before the case comes before the courts, and his ailment and symptoms greatly magnified and increased while the case is on trial, who, when the jury rendered a large verdict in his favor, and almost simultaneously with the receipt of the check for the payment of his supposed wrongs, proceeds to the almost magic recovery of his former good health—of this class of fraudulent claims I desire to speak, and can see no reason why, in a court of equity, such cases of fraud can not be made to convert to the rightful owner the proceeds of the verdict so fraudulently obtained.

I am not aware of any effort ever having been made by any corporation to recover in a court of justice in such cases, and I think, should it be proven that the attorney in the case accepted the pushing of all such cases before the courts, upon a commission to be paid him from the proceeds of the verdict, and it can be shown afterward that the case is fraudulent, that he would be equally co-respondent with the prosecutor, and likewise amenable to the same treatment as the claimant.

In the recovery of money so obtained he should, in fact, be made a co-defendant in such cases in courts of equity. If possible to recover in a few well-conducted cases, is it not possible that it will point out

the way whereby those who now present such cases in court would hesitate before pushing such alleged injuries into litigation, and thus be the means of eliminating from damage accounts vast sums of money now unlawfully and wrongfully obtained?

The question might be propounded: How are we to prove the fact that the recipient of such favors by the courts of litigation are malingerers? "Out of the fullness of the heart the mouth speaketh." Only by his actions, and this is quite easy of accomplishment. Let us suppose the claimant in his declaration alleges total disability of one of the extremities. By proper coaching in auto-suggestion he will carry out the play entrusted to him by his informant, but will he do so after he has obtained the balm of a good sized verdict that can alone soothe the pangs of imaginary pain? Think for a moment that he can not, by any process of law, be compelled to return any part of the proceeds of his ill-gotten gains. No! And thus in a very short time he will so forget himself that his own actions will be sufficient to furnish such proof as would be needed to convict himself.

There is but little use in reviewing individual cases before the Fellows of the Academy. We have only too many such examples of perfidy upon the records of almost every court in the land.

This question of perjury is one that does not carry its import and penalty deep into the minds of the majority of litigants who are unscrupulous enough to accept a large reward from corporations for the settlement of malingering claims. If a few well marked examples of such cases of perfidy could be carried to a successful issue and to a conviction, it would be well worth the time and means expended upon the subject, for the penalty in almost every State is so great as to debar the perjured person, upon conviction, from many of the rights of citizenship.

In Pennsylvania it becomes a misdemeanor and, upon conviction, a fine of \$500, imprisonment by separate and solitary confinement at labor for a term of years, and it forever disqualifies him from being a witness in any matter of controversy.

While doubtless this subject belongs to the legal department of railways, it is yet true that the aid of the surgeon must be called into the study of the surgical consideration of the same, hence making it a medico-legal one, and as such can be rightly considered and discussed by the Academy.

We are trespassing upon virgin grounds and, perchance, are ill fitted to consider and bring out a sufficient number of points, convincing in character, to maintain the position taken. With some degree of truth it can be said that such action would be beneath the dignity of a large corporation. We hold that when right and truth are on the side of the latter, nothing can be adduced by the malingerer to balance the scales in his favor. For right and truth should and must prevail.

With this brief recitation of this somewhat intricate subject, I desire not to prolong it, but gladly submit the question to the Fellows of the Academy who are more learned in legal lore than I.

DISCUSSION.

MR. BECKER—Although not a member of the Academy, I will simply make a suggestion: That the claim for injuries may be handled to more advantage in those States where statutes have been passed permitting an examination by physicians of the plaintiff before trial. It was long doubted whether the sanctity of the person was such that it would be unconstitu-

tional to adopt such statute. That matter has been put at rest by the U. S. supreme court, and by the court of appeals of New York, which have held that there was no constitutional prohibition, at least in the State of New York, which forbids the adoption of such statutes. There is now in force a statute in the State of New York in which it is the right of any defendant in a case founded upon personal injuries, to have an examination of the plaintiff before trial by competent physicians. I lately had occasion in practice to put that in effect in a case very closely allied to this referred to by our learned friend in his paper, and discovered with very little difficulty that no such extensive injuries existed as was claimed. It seems to me that the remedy is easily to be found there. In very few cases of a proper examination before trial would fraud escape detection, and the extent of the examination is largely in the discretion of the court. I know of no other State that has adopted that statute except New York; there is such statute in New York that permits the examination of the party, describes how it should be taken, in the presence of a referee, by a physician duly qualified. There is, however, a ludicrous feature about it. Some generous-hearted individual in the legislature secured an amendment to the statute, providing that in a case where a lady is the plaintiff, she is to be examined by a physician of her own sex. It is a ridiculous thing in the statute. A good many speak of it as a kind of joke; it was so regarded at the time it passed, but it slipped through without objection.

DR. HATCH—I represent the Burlington & Quincy. There is a case now pending, a threatened lawsuit. These parties were injured about six weeks ago and they demand damages from the railroad company, and they employed an attorney. I represented the company, told them that if the company was liable and they were injured it was not our desire to have any litigation and I demanded an examination of the parties which they absolutely refused. I contend that as a representative of the company I have a right to do this.

MR. BECKER—The supreme court of the United States held that the right does not exist independent of the statute. There is no right unless there is some statutory action that permits it.

DR. GARDNER—I can relate a case similar to the one my friend here relates. It is the case of an injury on the Southern Pacific last October. As chief surgeon of the company I was sent down by our chief attorney to investigate the case and asked for an examination of the case by our physician at Los Angeles. It was refused. The request was made by Dr. Ainsworth through me and I was to be present. The case finally came to trial and in that case the request, such as my friend Dr. Hatch spoke of, was placed in court as a request of the company to show that we wanted to treat them fairly and to make the examination by not only myself, but a physician in the employ of our company. As a result the case was non-suited and finally was disbarred entirely. The moment you place the fact before a jury that a man refuses to be examined by a competent physician, who is recognized as reputable in the neighborhood and in the city in which he lives, it bears a certain weight with the jury and invariably the verdict is the other way.

DR. MAYNARD—My judicial friend on the right here has presented this case well, but I object to papers of that character being read and printed by this Academy. I have had twenty-odd years' experience with railway companies, and I know there is no gentleman in this room who does not know that the general managers or the claim departments of the different roads are inclined to use us simply as adjuncts to the claim department, and I do not propose in my railway service to be held in any such light. The more papers we have in that line, and the more discussion we have printed, the more we will be likely to be regarded as adjuncts to the claim department of the different roads. Our motto is: "The higher the order of railway surgery the greater the protection to the employé, the

passenger and the company." and I think we ought to confine ourselves exclusively to that, and not make ourselves, any further than we can help, fifth wheels of the claim department.

DR. GARDNER—I take exceptions to those remarks. In my instructions in my department, I will not allow a surgeon in my service to appear as an expert under any circumstances but purely to testify as to facts. It is a procedure I have adopted in my service and I insist upon it. I shall never compromise, and a man in my employ who goes up as an expert loses his job.

DR. DALBY—I do not see very much relevancy between the remarks of Dr. Gardner and our friend from Cheyenne, so I expect we are all in line. I think Dr. Kibler's paper is a good paper. The question as to the merit or demerit of its publication in our proceedings is one for the Association itself to determine. I think that our relationship with the various attorneys and railway organizations is a very close one. No railway organization can go into court with a suit without depending and relying more or less upon the officers of that company. I do not believe that they look upon us as the fifth wheel or the seventeenth wheel of the claim department, but they certainly do look upon us as being able to give them some information which we do have and which I think it is proper for us to give. Speaking on the question of getting damages on perjured testimony, it is something that those connected with a railway have often seen. It is brought about by various conditions. In Salt Lake City, invariably every man, woman and child bring suit against a railroad company, it makes no difference whether they have any visible mark or not, the suit is brought and the jury will invariably find for them in various amounts. I recall now, among several instances, a case involving an examination of the injuries. Six or seven months ago we had a suit brought against the Union Pacific Railway on the part of a mother and daughter. The mother was a lady of middle age, and the daughter somewhere in the vicinity of 20. The mother claimed damages for injury to the spine, the daughter brought suit for a fracture of the nose. Neither of these cases had been treated at any time by any surgeon who had any connection with the company proper at all. They were each suing for \$5,000 damages. The solicitors of our road asked permission of the court to grant me the privilege of examining them, as the company itself had no evidence or no idea as to the extent of these alleged damages. The court finally permitted me to examine the daughter for a fractured nose, in company with her attending physician, but denied me the privilege of examining the mother. Where the distinction came in I do not know. But in carrying out the ideas of the paper that the doctor just read, obtaining verdicts on perjured testimony, there was a girl who had been enticed to go into court for a claim of \$5,000 for a fractured nose. Her attendant physician claims he examined her nose and found some irregularity in the nasal passage; in other words, the nasal passages were not alike. He described very graphically during the trial of the case the condition of the girl. As a matter of fact, and as he agreed with me in the examination I made with him, there was a turbinated bone, which merely loosened up the one muscle. That was where he found his fracture, and that was all that existed. At any rate the jury returned a verdict for her mother for \$5,000 and the daughter for \$2,500, and I got the reputation of being a railway hireling for my own testimony.

Otherwise All Right! Doctor: "Well, madam, how are you to-day?" Madam: "Oh, doctor, I have frightful pains all over my whole body, and it seems impossible to breathe; of course I can't sleep, and I have no appetite at all." Doctor: "Um—er well, otherwise you're all right, aren't you?" *Medical Press.*

CEREBRAL SYPHILIS, WITH REPORT OF CASES.

Read before the Chicago Pathological Society, April 13, 1896.

BY WILLIAM HESSERT, M.D.

Attending Surgeon German Hospital; Instructor in Medicine, Northwestern University Medical School.

CHICAGO.

I need offer no apology for the introduction of a subject such as this, as it is well deserving of our attention by virtue of its high degree of importance in diagnosis and treatment. The frequency of syphilis of the nervous system is becoming more and more appreciated, thus securing for it an earlier recognition and the establishment of a more definite train of clinical phenomena than formerly. Gray, writing only four years ago, would make no more than a tentative diagnosis of cerebral syphilis, unless there were present, 1, undoubted specific infection; 2, convulsions or hemiplegia, or 3, marked success of specific treatment. Gowers, in his great work, allots to nervous syphilis no special chapter, referring to it among causative agents in the production of endarteritis, cerebral softening, hemorrhage, insanity, etc. I need not dwell upon the widespread prevalence of syphilis, which is one of the most important diseases with which we have to deal. Additions are made daily to the already enormous literature. How many of these cases of syphilis have undergone treatment which can be called approximately curative? Those that submit to the proper régime are certainly in the minority. Only too many of them are lulled into a state of false security by the rapid disappearance of tangible evidence of the disease, and discontinue treatment despite the admonition of the medical attendant.

A chancre of doubtful nature heals under indifferent treatment, or perchance is cauterized; no "secondaries" follow, leaving the individual in doubt whether he is syphilitic, until a subsequent nervous affection is undeniable evidence thereof. Fournier says that just those cases in which the manifestations on the skin and mucus membranes are scanty or absent, are prone to be followed by nervous lesions later on. Especially does this seem to obtain in women, who also are often infected unknowingly, a circumstance which provokes distressing errors in diagnosis, especially among the better classes.

On the other hand, a conscientious course of treatment for one and one-half to two years or more does not necessarily insure immunity from further trouble. Recognizing, then, the ubiquitous nature of syphilis, we should ever be on the alert in cases of nervous, especially cerebral, disease, to establish a possible etiologic connection. It will appear that an early diagnosis of these cases of cerebral syphilis, before irreparable secondary changes have been wrought, is of incalculable importance. After secondary degeneration and softening have become manifest, treatment will avail but little, and can not be compared to the success achieved in cases where the alterations are limited mostly to the membranes and arteries. It is for us to heed the warning note that is sounded by the appearance of prodromal headaches, irregular palsies of cranial nerves or slight aphasia, and not wait until a greater calamity overtakes the patient.

A maxim to which I heard Max Joseph, of Berlin, allude is a good one, *ubi dubio, suppone luenem*, and safely applicable in medicine generally, as it can do no harm and may be the key to the solution of a perplex-

ing problem in diagnosis. Various well defined types of nervous disease, foremost locomotor ataxia and dementia paralytica, are said to occur with relative frequency following syphilis. Storbeck, of Leyden's clinic, has recently published a table showing the percentage of syphilitic cases in tabes according to forty-eight authors, from the 0 per cent. of Mayer to the 97 per cent. of Déjerme. In his own cases (108) about 30.6 per cent. had syphilis, which he thinks is not higher than might be expected from the frequency of the disease. Leyden is loth to admit any causative relation between syphilis and tabes. The relation of cause and effect in these cases has thus far been only statistical and not based upon pathology, nor supported by the results of treatment.

The cases to which I will refer are due to a direct involvement of the brain and its investments by the specific proliferative changes. These changes are the same in the brain and cord and cause outward symptoms in so far as they produce local anemias with their sequelæ or interfere with nerve conduction by pressure. The nervous involvement of syphilis is usually classed among the late manifestations, yet it has been known to follow infection from a few months to thirty years thereafter. According to Naunyn, nervous syphilis occurs most frequently during the first year following infection, and decreases year by year thereafter. Many cases have been reported of late, occurring within the first year and during the period of efflorescence (J. Hutchinson and G. F. Lydston). Most cases, however, develop after the lapse of several years. I will say that the tendency now is such as to disregard the arbitrary division of syphilis into "secondary" and "tertiary" periods, since the manifestations thereof are found to intermingle to a degree not consistent with any such classification.

Age is variable, averaging 30 to 35, youthful individuals being more often stricken, and males preponderate. To Sternberg (1860) and Heubner (1874) belong the honor of having first identified certain cerebro-spinal meningitic and arterial changes with syphilis. Save minor details their works still enjoy acceptance. Rumpf also asserts that syphilitic disease of the nervous system originates primarily in the blood vessels.

Syphilitic lepto-meningitis, like the tubercular, is prone to affect the base of the brain, about and posterior to the optic chiasm, whence it spreads to the convexity. Separate foci in different stages of development may coexist. The pia and arachnoid are primarily involved; as they span the interpeduncular space they appear thickened, opaque and pultaceous. The mass is granulation tissue, which becomes fibrous, sometimes cheesy. The membranes adhere to the cortex, which suffers to a variable degree. The new growth fills out the sulci, thereby smoothing the markings of the convolutions. The cranial nerves and cerebral arteries traversing these masses can not escape involvement, but they are often independently affected. The nerves are infiltrated with round cells producing nodular gummatous thickenings; eventually nerve atrophy occurs. Owing to their situation the optic, third and sixth nerves are first to be attacked, the others escaping more or less.

The arterial changes are those of an endarteritis obliterans; the intima becomes enormously thickened by the growth and organization of round cells, which invade to a lesser extent the other coats. There results progressive narrowing of the lumen and even-

tually complete occlusion of the same by the cell growth or by thrombosis. As in the nerves, small gummosities occur in the vessel walls. Aneurysms and hemorrhage are uncommon, thrombosis being the most frequent event. Section of the brain sometimes reveals no changes save the arterial. There is never any pus formation and gummata in the interior are infrequent. The effects, secondary and remote, produced in the central ganglia and internal capsule are of vital importance. The arteria fossa sylvii, which supplies motor regions of vital function, is commonly involved by endarteritis. By the narrowing of the lumen, aided by the varying degree of blood pressure, there are produced vacillating states of anemia, until finally occlusion by a clot produces ischemia in areas of variable size with resultant monoplegia, hemiplegia or aphasia. These latter, rarely hemiplegia, are also evoked by pressure of meningitis overlying motor centers; convulsions may then precede paralysis. If the deprivation of blood be not soon relieved by collateral supply or perviousness of the thrombus, softening with its sequelæ is inevitable.

All writers agree upon certain factors which enhance the tendency to nervous involvement. These are inebriety, venereal excesses, emotional disturbances, worry and overwork; sometimes trauma to the skull.

The character of the pathologic lesions, manifest by their insidious, vacillating and irregular growth and regression—the simultaneous involvement of widely separated areas—the far-reaching influence of impeded blood supply—all these elements obtain in determining a clinical picture of varying aspect. This irregularity, however, is one of the points of identification, together with phenomena which are uniformly constant. Headache is among the first fore-runners, often nocturnal and periodic and frequently localized. Its severity may reach an agonizing degree, accompanied by great sensitiveness to percussion of the skull. The cephalalgia may be accompanied by nausea, vomiting or vertigo. This may be the only complaint for weeks and months, even years, until superseded by the first signs of paralysis. There is usually an early psychic involvement, evinced by a change of character, the individual becoming moody, morose, sullen and hypochondriacal. He is, too, drowsy by day and wears a stupid sleepy look, but is restless and wakeful at night. The keen intelligence is blunted and the memory fails; he shuns society suspiciously. Sooner or later an inability to read and write is noticed and finally the first signs of paralysis appear. It is claimed that with the onset of paralysis headache and vertigo subside.

The palsies are very various, from a paresis of an ocular muscle to complete hemiplegia. Aphasia is frequent and may be the only motor disturbance. The speech, at first irresolute and halting, resembling paralytic dementia, finally becomes inarticulate and the function is completely suspended. The meaning of words is understood, as the aphasia is of the motor type.

I have already referred to the early affection of the optic, oculomotor and sixth nerves, less frequently the fifth, seventh and others. The optic disk reveals neuritis varying from a reddening and blurring of the contour with venous engorgement and swelling of the papilla, to complete atrophy, with a tendon like aspect of the nerve. Vision may be much reduced, and hemianopsia bitemporal or bilateral and

diplopia also occur. Oppenheim calls attention to the fleeting and transient nature of the subjective eye symptoms, especially the hemianopsia and contraction of the field of vision. The pupils may be sluggish and unequal and not react to light nor accommodation. Ptosis and strabismus are very common, more so than facial paralysis. The tongue is protruded to the side and the uvula is drawn from the perpendicular. Deafness is rare. These paralyses are often so disposed as to defy localization at one focus. The graver forms of paralysis, monoplegia and hemiplegia, may be of sudden apoplectic form onset or may develop after hours or days. Consciousness is usually retained, the patient experiencing the more or less rapid loss of power in his limbs. Death during such an attack is not the common outcome, but convulsions and coma are usually fatal. Polydipsia and polyuria occur in some cases, also atony of the bladder and rectum, generally transient. Paresthesias and anesthetics occur where sensory tracts are implicated. Fever is usually absent, although there may be some rise in temperature sometimes.

The course of the disease depends largely upon the gravity of secondary changes at the time of commencing treatment. Some cases continue for months or years with only headache or slight mental alteration, perchance paresis in the distribution of some cranial nerve. Others progress rapidly to convulsions, dementia and coma. Some are stricken with hemiplegia, terminating in contractures and atrophy. There may be periods of quiescence, but relapses are possible.

I can not too much emphasize the enormous importance of an early diagnosis, upon which the whole future of the case hinges. If recognized and treated early, the outlook is generally good but becomes progressively worse the later treatment is begun. According to Naunyn the prognosis is favorable during the first four weeks, and after the commencement of treatment, the bulk of improvement will have occurred by the end of the second week thereof. These are two valuable points to bear in mind when rendering prognoses.

The success of treatment is entirely dependent upon the amount of damage done to nervous substance secondary to the development of specific changes in membranes and arteries. If limited to these latter complete recovery can be assured. If the granulations be by treatment brought to absorption before the secondary alterations are of long standing and permanent, restitution is probable. Buzzard tells of an artery that had been almost occluded, tested by the sphygmograph, and yet it was again made patulous by proper treatment. Irreparable degenerative processes in brain and nerves, with muscular degeneration and atrophy can not be much improved.

We should be suspicious of the presence of brain syphilis under the following conditions:

1. Headache, periodic, nocturnal or localized, accompanied by nausea and vertigo, or the development of mental symptoms described above.
2. Isolated irregular paresis of cranial nerves, especially the third, preceded or not by the above or accompanied by aphasia, alexia and agraphia.
3. Hemiplegia, in youthful individuals occurring slowly or sudden, with no loss of consciousness.
4. Coma and convulsions excluding opium, epilepsy, alcohol, diabetes, uremia and trauma extending over days.

Naturally, our suspicions are confirmed by a clear specific history or the simultaneous appearance on skin or mucous membranes of typical lesions.

Is complete recovery possible? Mills says "it is possible to remedy some of the effects of nervous syphilis or to remove some of its symptoms; it is even possible that a cure may be effected; but this, as Gowers asserts, has never been proved." The fallacy of this statement is evident and shown by cases reported by Gray, Althaus, Lydston, Diller, Hutchinson and others. Three of my cases recovered completely; one was greatly improved when last seen; one, seen late in the disease, died; one is still under treatment, much improved. I believe that if the proper conditions before mentioned are present, that a speedy and absolute recovery can be secured in a large majority of the cases but that a relapse, as Fournier says, is possible, unless treatment be continued at least two years.

The treatment is that of a syphilis in general, but should be vigorous and the remedies should, when necessary, be pushed to the limit. The "schools" are divided on the relative merits of mercurials and iodids. Gowers claims that on the whole the iodids are the most useful and certain of the two. This opinion is upheld in America generally, and enormous doses of iodids are given, an ounce or more of iodid of potash in the twenty-four hours. Germans rely more on inunctions of mercury, but all use the "mixed treatment." I agree with Lydston as to mercury "first, last and all the time." His suggestion, however, as to its mode of application is as unique as it is impracticable, viz., to rub the patient's scalp and neck with blue ointment so that the seat of trouble may be sooner reached and more directly! This suggestion is totally at variance with the teachings relative to the absorption of mercurial ointment. The opinion has spread, based on experiments of Lewin, Müller, Joseph and others, that most of the mercury applied to the skin is in reality absorbed by the lungs, the lesser portion finding access directly through the skin. It is sufficient to apply the ointment without any rubbing, avoiding the hairy regions of the body. Spread upon cloths and hung up in syphilitic wards, patients therein recovered from milder symptoms without any other treatment, meanwhile excreting abundant mercury with the urine.

The cases to follow were treated with one drachm of unguentum hydrargyri and a drachm more or less of iodid of potash daily. In all of the cases, except the female, the question of syphilis is positive. Collectively they illustrate most of the variations of the subject under discussion and are typical cases of their kind.

Case 1. Male, age 28, chancre eight years ago. Aphasia, slight dementia, agraphia, alexia, unequal pupils, paresis of lower facial; recovery in four weeks.

The chancre, eight years since healed under indifferent treatment and had no characteristics of syphilis. No eruption nor sore throat followed. Five years later had a periostitis of sternal end of left clavicle. The present illness began with change in character: he became sullen and morose, walked the floor nights on account of headache and insomnia, whereas by day he was sleepy and would doze during conversation. After a few weeks an alteration of speech became apparent, it was slow and halting, finally becoming inarticulate. It was then found that he could not read nor write. Pupils reacted sluggish, right dilated; slight paresis of right lower facial branches; uvula deviated to left; tongue in median line. No sensory disturbances. Treatment was at once instituted, after three days its effects were apparent, and at the end of four weeks all signs had disappeared except an impairment of the mental

faculties, which remained somewhat dull and lethargic. For six months he used inunctions and ever since he has taken iodids off and on. At present, after nearly three years he is apparently perfectly well, does office work but is still eccentric. At no time during his disease were there any palpable signs of syphilis other than the nervous. In this case the meningitis affected chiefly the speech center, to less extent the base.

Case 2.—Female, married, age 43. No specific history; nocturnal headache and vertigo very severe for four weeks; then left hemiplegia and optic neuritis; recovery almost complete in three weeks.

This patient had five healthy children, two still births; youngest child about eight months old and healthy. Denies infection. No previous illnesses. Began four weeks ago with severe headache, worse at night, located in vertex and right temporal region; vertigo, vomiting and general malaise. Then she developed a left-sided hemiparesis, coming on in the course of a few hours with consciousness retained. Unable to walk, left hand grasp feeble, face somewhat drawn to right, sensation on left side impaired. No convulsions; speech unimpaired; pupils equal and react. Had complained of dimness of vision for few days previous; neuro-retinitis right side. Great sensitiveness to percussion over right temporal region. Treatment begun immediately after onset of paresis. Headache gone on third day and great improvement after one week. In three weeks muscular power almost restored, sensation returned; no headache; neuro-retinitis abating. She was feeling very well and passed from observation. Subsequent history not known. She also, when seen, had no signs of syphilis, but the character of the illness was highly suspicious of syphilis and was corroborated by the brilliant results of anti-syphilitic treatment.

Case 3.—Infection seven years ago. Complete right hemiplegia and aphasia without loss of consciousness; polydipsia and polyuria; complete recovery.

Patient was a male, age 42; acquired syphilis seven years ago; had slight eruption and sore throat. Was treated for eighteen months with inunctions and pills of protoiodid of mercury with iodids. He considered himself cured and took no treatment since. Patient is addicted to excesses in alcohol, tobacco and venery and owing to the speculative character of his business his nerves are continually on a high tension; he is of a violent and excitable temper. Returning home late one night after a turbulent celebration in honor of an important business transaction, he suddenly felt a sense of weakness in right side of body and tottered to the nearest support. He had had no headaches recently and was feeling as well as usual. He did not fall to the floor nor did he lose consciousness. After regaining his composure he found that he was not completely paralyzed, and a physician who saw him soon after was able to get a history from him. He also complained then of a headache on the left side. Next morning paralysis and speech worse, and in the afternoon, about eighteen hours from time of onset the condition was as follows: Complete motor aphasia; right pupil larger than left, reaction sluggish; tongue protruded to right; complete right hemiplegia and impairment of sensation. Atony of the bladder and rectum. Sensorium in a somewhat dazed condition. Knowing absolutely his previous history, he was immediately put on anti-syphilitic treatment and improvement progressed after the second day. After two weeks speech was normal; he could walk with support, sensation slightly blunted, flexes fingers and moves arm slightly. Sensorium clear, sleeps well, no headache; has great appetite and thirst, and voids large quantities of urine, which contains no albumin nor sugar. After four weeks, walks about and moves right arm freely, but not with former power yet; face symmetrical, tongue in middle line, pupils equal. Sensation and speech restored. After this, recovery was steady and uneventful and at the present time, nine months after the onset, patient is conducting a large business concern and says he never felt better in his life. He still takes mercurial pills. This case illustrates how after a fair initial course of treatment cerebral syphilis may follow later; that absolute recovery is possible.

Case 4.—Chancre eleven years ago; headache for last year; aphasia getting worse for two months with agraphia and alexia; improved.

Patient is a male, age 33, clerk, acquired syphilis eleven years ago. Habits regular and moderate. For the last year or so has suffered periodically with headaches, sometimes worse at night; no vertigo. Eight weeks ago while traveling on business he became aware of a heaviness of speech with defective memory. He would forget his destination, neglected his business and lost his former sharpness in business dealings. He gave up and returned home and sought relief in various quarters, but his condition became worse. None whom he

consulted treated him for syphilis, as he, like the preceding cases showed no palpable signs; one advised him to marry. After eight weeks his condition was the following: Patient could utter scarcely intelligible words; the foregoing history was obtained from his father. His expression was stupid and dull in contrast to his former brightness. All movements were slow and languid. Marked tremor of face and hands. Pupils equal and react. No paralysis anywhere save the speech; can not read nor write. Physical examination negative except very slight general adenopathy. Was at once put on specific treatment, but after a few days developed iodism and the drug was stopped, but the inunction continued. After about four weeks' treatment he is back at work, talks, reads and writes as usual; memory as before; tremor entirely disappeared; no headaches—in fact, he feels as well as he ever did, but is still using inunctions. He was apparently quite well for about ten days and then according to the family, he changed again. He became forgetful again, said many foolish and untrue things, was restless at night, squandered money carelessly; in fact, his character quite changed. He is using inunctions and increasing doses of iodids.

Case 5.—Papulo-pustular syphilid; headache, paresis of left arm and leg with no loss of consciousness; optic neuritis; in four weeks almost complete recovery excepting the optic neuritis.

Patient is a male, age 43. No previous illness; uses alcohol moderately; denies a chancre. For nine weeks he has suffered with headaches, worst at night; vertigo at times recurring in paroxysms and becoming worse. A few days ago he first noticed a weakness in his left arm and leg accompanied by a tingling sensation and numbness. This loss of power came on gradually and he was at all times conscious. Speech unimpaired, mental condition as usual. He says the paresis and the skin eruption appeared about the same time. On examination pupils were equal and react; face symmetrical; tongue protruded somewhat to left. Marked weakness of left arm and leg, but some motion is retained, as he can walk dragging his left leg. Knee reflex equal but pronounced; ankle clonus on left side. Hyperesthesia, especially of left arm. General macular, papular and pustular syphilid and mucous patches in mouth. General adenopathy; internal examination was negative. He complained of dimness of vision. Ophthalmoscopic examination showed on the right side venous engorgement, papilla reddened and blurred, slightly swollen. On left side the changes were less marked. Treatment was then begun and its effects were very evident by the end of a week in the cessation of headache and returning power on left side. In four weeks eruption had disappeared; both sides about equal in strength, reflexes equal, no clonus, sensation normal. The optic neuritis had abated considerably, but vision was still impaired. At this time he passed from observation and the further course is not obtainable.

Case 6.—Evidence of syphilis; headache and dizziness; change in temperament; drowsiness deepening into coma; optic neuritis; paresis right facial and left arm and leg; ptosis slight on left side; death in coma on tenth day; autopsy, no gross lesions disseminated endarteritis.

Patient, a male, cook, age 38, was already semi-stuporous when first seen, so that a good previous history was not to be had. He had some kind of skin eruption one year ago. For some weeks preceding present illness he is said to have had headache and vertigo, and his mild temper changed to a violent and irritable one with emotional outbreaks. His drowsiness deepened rapidly of late. Examination reveals patient semi-comatose, but he can be aroused sufficiently to answer some questions. Slight ptosis on left side; movements of eyes free. Pupils irregular and immobile; under atropin they dilated irregularly, tearing up iritic adhesions to lens. Interstitial keratitis on left side preventing examination of fundus. Optic neuritis on right side of moderate degree. Paresis in distribution of right lower facial. Tongue dry and protruded irregularly. Slight paresis of left arm and leg with hyperesthesia. General adenopathy. Reflexes normal. Involuntary defecation and urination. Temperature normal, pulse 95 to 90. The urine contained albumin with hyalin and granular casts and abundant leucin crystals, but no tyrosin: the amount could not be estimated. On the usual treatment he improved for the first five days—he became brighter, the paresis of left arm and leg disappeared, but the ptosis and right facial palsy remained. He can give a few simple answers, but is still very dull and sleeps a great deal. No tenderness on percussing skull. Urine contains less tyrosin. Occasional projectile vomiting. No convulsive twitchings were noticed. On the eighth day the drowsiness again deepened and patient died on the tenth day in deep coma. Autopsy: Slight meningeal thickening at base of brain; no fresh inflammation. Cranial nerves apparently nor-

mal. Endarteritis obliterans of anterior and middle cerebral arteries, but no complete occlusion nor thrombosis was found. No aneurysms nor hemorrhage. No gross macroscopic lesions of brain. Of the other organs of interest the kidneys showed a condition of subacute parenchymatous nephritis.

I believe that we have sufficient proof of syphilis in the keratitis, iritis, adenopathy and clinical course of the disease, although the post-mortem findings are not conclusive, being limited in the brain mostly to the arteries. I will not deny that there may also have been a uremic element in the case. I will offer no explanation for the presence of leucin in the urine, occurring as it does most commonly in acute yellow atrophy of the liver, phosphorus poisoning, leukemia and various infectious diseases.

DISCUSSION.

DR. MOYER—It needs no emphasis at this time to point out the immense importance of syphilis as a causative factor in disease of the brain and spinal cord. There is, however, a trifling misconception growing out of the mere use of terms. I see the doctor has labeled his paper, cerebral syphilis with report of cases, and he referred to the fact that Gowers had no chapter in his work on this subject. He would probably not find one upon syphilis of the spinal cord, and yet most of our German confrères have a chapter devoted to these subjects. It is not, however, that the English and American neurologists and the practitioner of general medicine do not recognize the importance of syphilis in the etiology of these disorders. The term cerebral syphilis and syphilis of the spinal cord, as used by our German confrères, is incorrect, as it puts into the nomenclature a new pathologic entity, like chorea, tabes, etc., a something which is caused by syphilis. We do not think it is possible to distinguish clinically the cases of tabes and parietic dementia having their origin in syphilis from those caused by other conditions. There is no doubt that most of the cases occurring in the meninges along the base of the brain, involving one or more of the cranial nerves, or a cerebral peduncle, or perhaps a single branch of the third nerve, or those which occur with a comparatively abrupt onset of symptoms, those cases are almost without exception syphilitic, but I do not think this justifies the term cerebral syphilis; I should say rather they were such and such conditions, affecting certain portions of the brain as the case might be, which were caused by syphilis. There was one case described in the paper which to my mind might justify the term cerebral syphilis. It was the one in which a diffuse endarteritis was found, but no local lesions. I believe that makes a clinical type that perhaps ought to have a chapter in works upon practice labeled cerebral syphilis. I have seen several such cases in which there was a rather abrupt onset with scarcely any local paralysis, early interference with speech and sluggishness of the pupils; some exaltation of the mental functions, rapidly passing on into mild delirium, stupor and death. At the post-mortem, the findings are not different from those described by the doctor; but, as I say, this discussion really relates to terms and not to facts. The great importance of the doctor's paper is in directing our attention very pointedly to the influence of syphilis in these affections, and particularly in the cases that he describes, those presenting irregular manifestations and those with a comparatively abrupt onset, but this has been recognized for the last twenty years. Within the last eight or ten years, there has been an increasing importance attached to syphilis in the slow progressive degenerations, the ordinary cases of parietic dementia and tabes, and we must now admit, although

still denied by a few, that syphilis causes 80 or 90 per cent., or even more of these cases. There is, too, a striking difference in regard to treatment in this class of cases. Those with an abrupt onset are usually quite amenable to treatment; those in which the symptoms come on slowly and insidiously are most rebellious to treatment, no matter how energetically pursued, and I think the reason is found in the fact that the changes in these other conditions are really secondary. Take, for instance, an endarteritis that leads to a rupture of an artery or thrombosis. The secondary conditions are not amenable to anti-syphilitic treatment. The same applies to cases of insidious onset, in which specific treatment does so little and yet it is undoubtedly true that they are of syphilitic origin. The reason of it is that this slow, progressive syphilitic endarteritis has set up the secondary changes, sclerotic in character, and when those changes are once set up, it makes no difference what the cause is, the treatment is practically *nil*, no matter how energetically pursued. But coming to the practical point; the evidence is now so strong that in all these cases it is the duty of the practitioner, even in the absence of a history of syphilis and even where it is denied, to give an energetic anti-syphilitic treatment. I prefer the mixed treatment, but give the iodids in relatively very large doses.

DR. WM. HESSERT—I think that Dr. Moyer and I agree, only that we express our views in different ways. I meant to say that the subject of cerebral involvement by syphilis has been described as an entity under a special heading of late by German authors; especially Oppenheim in his last work gives a classic description of cerebral syphilis, meningitis and inflammation of the cerebral cortex. I admit certainly that the subject of cerebral syphilis is as old as the subject of syphilis itself, and thousands of years ago we may say that mankind was affected with the cerebral involvement just as they are now; but the point is that it was not recognized as of late years.

PNEUMONIA; THE NON-ALCOHOLIC TREATMENT.

BY THOS. P. SCULLY, M.D.,

ROME, N. Y.

Contrary to all that has been written showing the pernicious effect of alcohol on the system in health and disease, and contrary to the admonitions of some of the greatest lights of the medical profession, past and present (a few of whom I may mention, viz., Sir Astley Cooper, Prof. Willard Parker, Dr. Benjamin Ward Richardson, Dr. Wm. B. Carpenter, Dr. N. S. Davis and numerous others equally as well known), as to its deleterious effects in disease, and notwithstanding the fact that the mortality rate from pneumonia is higher than fifty years ago, still we persist in using alcohol in pneumonia crouposa.

You can scarcely pick up a text-book or journal for reference as to the treatment of pneumonia, without being confronted with the fact that you must stimulate your patient with alcohol.

We boast of the great advancements made in surgery and medicine, and contrast our knowledge of to-day with that of fifty years ago. The contrast is certainly very great; our knowledge of materia medica and therapeutics is certainly very extensive; in diagnosis we have become very proficient, and we differentiate one disease from another with that degree of certainty that if some of the lights of the medical profession who lived fifty, or even twenty years ago, were to come to life, they would be amazed at the advancement made in diagnosis alone.

In treatment of disease their surprise might not be so great, because of the fact that we do not differ materially from the various ideas entertained in the past.

In pathology we have made the greatest advancements, and inasmuch as this article has to do only with pneumonia crouposa, we shall dwell on it more or less from a pathologic standpoint in order to show

why alcohol is contraindicated, and why it should not be used in pneumonia.

Pneumonia crouposa is distinctively an inflammatory disease, and as in all cases of inflammation occurring in any part of the body, so in the first stage of pneumonia we find a hyperemia or increased vascularity; engorgement.

In the second stage we have exudation, red hepatization, in which the alveoli and bronchioles become filled with a sero-plastic exudate, and that portion of the lung affected becomes partially solidified, and in it the blood current is apparently stopped.

The third stage is the one in which we find fatty degeneration of the exudate, and an extrusion of the same. It is called the stage of resolution.

Space will not permit, nor need we make a more elaborate description of the various minute pathologic changes that take place in the affected lung in order to prove the theory I advance. It will suffice to say, for all practical purposes, that we have an inflamed condition of lung to deal with, a congested, engorged condition of the blood vessels of the part affected, and later on a state of solidification in which all blood is excluded.

Now then, inasmuch as the foregoing statements are beyond dispute, having been accepted by all, we shall endeavor to prove from the above facts why alcohol is contraindicated in this disease.

In the first stage we find on microscopic examination the blood vessels to be distended with blood; that is to say, the volume of blood has been enormously increased and the capillary network surrounding the alveoli is greatly enlarged and all adjacent portions of bronchioles are similarly engorged; thus we have a hyperemia marking this stage of the inflammatory process, lasting from twenty-four to thirty-six hours.

We will now see what affect alcohol has on the system and compare it with the above.

According to the latest views, the physiologic action of alcohol on the arterial system is that it causes the heart to beat faster but not stronger. The increased heart beat is attributable to the dilatation of the arterioles; that is, there is less resistance to overcome and the heart therefore beats faster. It also, through its action on the vasomotor nerves, paralyzes the minute capillary vessels, and fills them with blood. In other words, it produces an hyperemic condition substantially the same as we find in the first stage of pneumonia.

Now then, if alcohol produces in health this condition of affairs, why is it not contraindicated in an already congested lung? Does it not assist in complicating a difficulty we are endeavoring to overcome?

Again, it is a well established fact that alcohol in the system diminishes oxidation, and inasmuch as the oxygen needed in the blood is received from the pulmonary air cells by the hemoglobin and serum of the blood, and in them conveyed to the systemic capillaries, where it comes in contact with and exerts its influence on every cell and structure of the body, and furthermore the feeble affinity it manifests for oxygen is offset by its strong affinity for water, albumin and hemoglobin. Therefore if alcohol is introduced in the circulation, instead of uniting with the oxygen, it manifests its strong affinity for the hemoglobin and sero-albumin, and consequently interferes with the reception of oxygen from the pulmonary air cells. In this manner the presence of alcohol prevents the hemoglobin from being converted into oxy-hemoglobin in

the pulmonary arterioles, and in the same ratio diminishes the amount of oxygen conveyed to the systemic capillaries, and in the same ratio the nerve sensibility and metabolic changes diminish.

Alcohol, as can be demonstrated, is a narcotic poison in large doses, and kills through suffocation by its paralyzing influence on the respiratory nerve-centers, and in small but continued doses it produces the same result by the structural changes which it produces in the organs and tissues of the body. By its action on the blood cells it checks oxidation by limiting their power of eliminating carbonic dioxid and of absorbing oxygen.

Therefore, if, as is above shown, alcohol prevents the elimination of carbonic dioxid and the reception of oxygen by the blood cells, how can we expect by introducing it into the circulation, that it is going to afford any relief to an already congested lung which is endeavoring to rid itself of an overabundance of carbonic dioxid, and to obtain more oxygen?

During the stages of red and gray hepatization up to the point when resolution takes place, we find the area of lung involved almost solid. The venous circulation falls abnormally and the right heart weakens from over-work, and as a result of this condition the patient has a flushed, anxious and slightly dusky countenance. We have substantially asphyxia, and in many cases the patient is in a semi-comatose condition. This condition is the result of carbonic dioxid poisoning and a lack of oxygen. The asphyxia is not necessarily due or dependent upon the amount of lung tissue involved, nor to any change in the heart muscle, but rather a toxemia which undoubtedly weakens the heart.

It is also an established fact that all natural molecular or metabolic changes, nutritive, secretory and disintegrating, taking place in the living tissues, are absolutely dependent on the presence and movement of blood containing its natural proportion of oxygen. Consequently it must follow that when this free movement of blood is interfered with, as it is in the solidified portion of the lung (as we find it in the second stage of pneumonia), the metabolic molecular changes taking place in the lung are interrupted, and as a result the blood is loaded with toxins. It is very evident, therefore, that we should direct our treatment so as to assist the system in ridding itself of these toxins.

Can we, by administering alcohol, accomplish this? I say unhesitatingly, no. I say so because of the fact that it is contraindicated, for the following reasons: The effect of alcohol in the system is to paralyze the minute capillary vessels and fill them with blood, thereby substantially producing a stasis. The removal of toxins, which have been produced by the diseased condition of the lung, is interfered with, and we have as a result a systemic poisoning.

How often have we observed, during the second stage of pneumonia, when a patient is apparently dying from asphyxia, the subnormal temperature, pulse hardly to be felt, cold perspiration, respiration labored and stertorous, a cyanotic appearance of the face and a more or less comatose condition? How often do we attribute all of the above symptoms to the venous stasis and carbonic dioxid poisoning, resulting from the diseased portion of the lung, to which it is true they may be due? But as a rule what have we been doing for the patient during this time? Filling him up with alcohol in order that we may, as

we have been taught, tide him over this condition by stimulating him.

The question now arises: How much of the above condition can we attribute to the disease and how much to alcohol? We shall answer the question in the following manner: The imbibition of small doses of alcohol produces through its action on the cerebro-spinal system a relaxation of all terminal capillaries, and there is no rise in temperature. In large doses or a very frequent repetition of the small dose, there is a partial paralysis of the terminal capillaries, a lowering of temperature, loss of muscular power, lack of coördination and finally more or less delirium, anesthesia and collapse. In larger doses it is a true poison.

Now then, inasmuch as the physiologic efficacy of alcohol is considered to be one ounce well diluted, taken in divided doses during twenty-four hours, any considerable quantity taken above this amount may be considered toxic, and being a true poison note the effect it produces on the system. In complete alcoholic poisoning, the temperature is subnormal, pulse hardly to be felt, cold perspiration, respiration labored and stertorous, pupils do not react to light and the lips are blue.

Observe the similarity of the symptoms of alcoholic poisoning and those of carbonic dioxid poisoning of the second stage of pneumonia, then ask yourself if you are justified in giving alcohol in any form in this condition. No more dangerous, pernicious treatment has ever been adopted or advised than to give, in this critical stage (or any other) of pneumonia, alcohol in any form or quantity. You are no more justified in administering alcohol in pneumonia than you would be in giving it in a case of alcoholic poisoning.

Dr. Henry Hartshorn stated in a paper read before the College of Physicians of Philadelphia, 1888, that pneumonia was much more fatal then than when the practice of venesection prevailed; and that the increased mortality could not be explained by change in type or change in constitution, and that it must be due to change in treatment; *ergo*, the modern treatment must be wrong. Then he goes on to prove, by statistics taken in Great Britain and Europe, and also this country, that the mortality from pneumonia was relatively twice as great then, than it was fifty years previously. It would be inferred from Dr. Hartshorn's article (as he says) that the reason for this greatly increased mortality, was we had dropped venesection and taken up a new line of treatment, and that, *ergo*, this new line of treatment was wrong.

Dr. Hartshorn is not alone in thinking that the modern method of treating pneumonia is wrong. Many of the older members of the profession will tell you that when they began the practice of medicine forty or fifty years ago, when it was customary to give a dose of calomel and bleed for almost everything, they did not have such a high death rate as we do to-day.

Dr. N. S. Davis, at the AMERICAN MEDICAL ASSOCIATION meeting in 1888, during the discussion on pneumonia, stated that it was a curious fact that the mortality was greater then than it was forty-five years before. He referred to the statements of a Canadian physician, "who stated that during a practice of thirty years he had adopted three plans of treatment. During the first decade the treatment consisted of blood-letting; the second decade constituted the transition from the blood-letting to the expectant plan; and the third the stimulating method. He found in

footing up his records that the mortality was least during the first decade and greatest during the last."

Although I must agree with Dr. Hartshorn and those older members of the profession as to the high mortality rate, still I can not attribute the higher mortality in this age to the lack of venesection. Some recent writers advocate venesection in special cases. I have never seen a case where I felt justified in venesection. I never could see any reason in blood-letting, particularly in pneumonia. I have noticed that those who do advocate blood-letting in pneumonia do so only in the early stages. The object, apparently, in venesection early in the disease is to relieve the over-loaded venous circulation, thereby assisting the right heart.

There are those of us who have never done any blood-letting, who have had sufficient experience in the treatment of pneumonia to warrant us in saying we do not think it should ever be resorted to. We have seen cases get well without being bled, that had they been attended by one who advocated blood-letting, and bled, the result would undoubtedly be attributed to the blood-letting.

The question of venesection has been so thoroughly discussed in years past, that we of this generation have considered it settled, and relegated to the past, but ever so often it seems we have to be reminded of the fact that it still has its advocates. We have such authors as Ziemssen, Hare, Austin Flint, Bartholow and others of equal note, to be cited as against venesection in pneumonia; consequently we say, do not bleed in pneumonia.

I attribute the favorable results in pneumonia of fifty years ago chiefly to two things: First to the almost universal use of calomel, and second, to the very limited use of alcohol. Calomel was used generally from the first to the last stage of the disease. The effect of this administration as a rule was to cause the bowels to move freely, oftentimes causing watery discharges; thus the physicians of those days were unconsciously using a remedy sanctioned by the leading lights of the profession of to-day; particularly by those who believe that pneumonia is a germ disease. Binz and others claim that calomel partly becomes converted into corrosive sublimate in the digestive tract, there unfolding its powerful antiseptic action. This disinfection and its coexisting purgative action, cleans the bowels to a very great extent of whatever germs may be present.

Whether we view the use of calomel from the standpoint of its being a germicide or not does not matter, but we do know that acting as a purgative it increases intestinal secretion, and has an indirect effect on the circulation by lowering the pressure of blood in the blood vessels, thus substantially producing what may be called a physiologic blood-letting, without the venesection and without the shock. It is not necessary that we should use calomel; any active cathartic or purgative would do as well; but the free movement of the bowels at the onset is indispensable, in fact is one of the cardinal principles in the treatment of pneumonia.

It is generally understood that if no complications set in, pneumonia (crouposa) is a very regular and typical disease. It is self-limited, and inasmuch as it is such, our chief aim should be to not interfere too zealously in natural processes, but by judicious handling bring about a favorable termination. Generally speaking the less medication the better.

Fothergill used to say that about every new remedy had to be used in pneumonia. The chief remedy in this disease is plenty of air. Liebmester (Ziems-sen's cyclopedia) says: "A patient with a high temperature can not take cold." Do not be afraid of too much air; good fresh air will be found beneficial in any case; but be careful to avoid drafts. See that your patient has plenty of nourishment, preferably in liquid form.

Do not give alcohol in any form during any stage of the disease. I firmly believe that the use of alcohol has been the chief cause of the high mortality in recent years. Let the fever alone. The danger is not from the fever but rather the heart, and inasmuch as all of the recent antipyretics act as heart depressants, we should be very cautious in their use in pneumonia. Stimulate your heart if necessary with digitalis, using a good reliable fluid extract; strychnia or nitro-glycerin. Oxygen should always be thought of when there is a tendency toward cyanosis. I have seen such excellent results follow its administration that I unhesitatingly say: Use oxygen in cyanosis and use it freely. I have never taken very kindly to cold packs or compresses and have resorted to their use only in a few cases. Still in those cases where I have used the cold compresses I was pleased with the result. Poul-tices are disagreeable things at best, and only tend to worry and fatigue the patient.

I use the chlorid of ammonia in preference to the carbonate, and use it up to the crisis and during convalescence.

OBSERVATIONS ON GUMMA OF THE HY- POPHYSIS; AND PRIMARY CARCI- NOMA OF THE URETER.

Read before the Chicago Pathological Society, April 13, 1896.

BY LUDVIG HEKTOEN, M.D.

CHICAGO.

GUMMA OF THE HYPOPHYSIS.

In hereditary syphilis, the hypophysis may be enlarged and indurated, due to connective tissue proliferation.¹ In acquired syphilis, gumma of the hypophysis has been described by Troisier,² Weigert,³ Barbacci,⁴ Birch-Hirschfeld⁵ and Sokoloff.⁶ In these cases there can not be much doubt concerning the truth of the diagnosis. In Troisier's case the origin of the gumma is referred to the capsule of the hypophysis. Boyce and Beadles⁷ detail a case of granulomatous infiltration of the hypophysis which they regard as tuberculous, but without having shown tubercle bacilli to be present. The same uncertainty of diagnosis is attached to Wagner's⁸ case of "tubercle of the pituitary," which he observed in a girl aged 13 years, without tuberculosis elsewhere.

The following case of gumma of the hypophysis consequently merits report on account of the rarity of the lesion:

Woman, age 45, died on the same day as she entered the hospital without being able to give any information concerning her history. The post-mortem was made twenty-four hours after death.

The anatomic diagnosis reads: Chronic interstitial nephritis; chronic perihepatitis and perisplenitis; syphilitic cirrhosis of the liver with gummata; gumma of the hypophysis; thick skull; chronic interstitial myocarditis. Bacteriologic examination showed the heart's blood, the lung, the liver, the kidney, and the spleen to be sterile. Only the liver and the hypophysis need to be described at this time.

The liver weighs 1,570 grams. It is adherent to the diaphragm, especially along the falciform ligament. The adhesions are firm and fibrous. The surface of the organ is irregular and in the vicinity of the falciform ligament are puckered cicatricial depressions in the bottom of which the tissue is firm and whitish in color. The consistence is firm. On the cut surface there is observed a marked but irregularly arranged increase in fibrous tissue, but this is also best marked about the insertion of the falciform ligament; here the substance of the organ contains whitish nodules or areas that are inclosed in puckered capsules of fibrous tissue from which trabeculae radiate in all directions. Larger, homogeneous districts are also present.

The hypophysis is about twice the usual normal size; it is firm, rather homogeneous and grayish-red on the cut surface; the walls of the sella turcica are rough. The hypophysis weighs 1.8 grams.

The skull, which is plagiocephalic, is unusually thick, measuring, at the line of the incision to remove the calvaria, from 8 to 10 mm. in thickness, its bone being very dense, the diploë almost entirely absent, or replaced by compact tissue.

Microscopic examination of the hypophysis shows the entire organ the seat of a diffuse round-cell infiltration, throughout which are scattered numerous multinucleated giant cells. Only in a few places are indistinct remnants of follicles present. There are present a few irregular areas of necrosis in which the substance is homogeneous or finely granular. Blood vessels are sparse and their walls are often diffusely infiltrated. There are no miliary tubercles at the periphery of the mass. Under high power the nuclei of the cells are seen to be oval, spindle-shaped and stained but lightly; or smaller, round and deeply colored. Irregular shaped nuclei are also present. The giant cells show the protoplasm to be red (eosin), finely granular or homogeneous, the nuclei being heaped up mostly at the periphery. Large, distinctly epithelioid cells are not present. The ground substance is homogeneous or freely granular with but slight filtration. In the distinctly necrotic districts are nuclear fragments of all shapes and sizes. Eight slides were examined carefully and repeatedly for tubercle bacilli (carbol-fuchsin) but with negative results.

The liver shows marked thickening in Glisson's capsule with areas of diffuse cell infiltration in which are giant cells and encapsulated necrotic districts. This is most marked near the surface of the organ. There are no tubercles in the sections. Tubercle bacilli were not found.

From this examination it is believed that the diagnosis of gumma of the hypophysis is justified upon the following grounds:

1. The absence of typical tubercles and of tubercle bacilli, the structure being that of a degenerating granuloma.
2. The presence of a distinctly syphilitic process in the liver.

⁷ Journal of Path. and Bact., Vol. i, No. 3, p. 359.

⁸ Arch. f. Heilkunde, Bd. ii, 1862.

3. The absence of tuberculosis in all of the organs ordinarily examined in a thorough post-mortem.

In this case the gumma was not large enough to give rise to any symptoms. In Birch-Hirschfeld's case (loc. cit.) the walnut-sized gumma gave rise to pressure symptoms. The present case is the only one associated with evident increase in the thickness of the skull and this association may very likely have been simply accidental or due to the same cause as the gumma, namely, the syphilitic infection. Gumma of the hypophysis is of evident clinical importance because the consecutive pressure effects ought to be removable under appropriate antisymphilitic treatment.

PRIMARY CARCINOMA OF THE URETER.

While it is not unusual for the ureter to become invaded by carcinoma extending from the uterus, the rectum or the urinary bladder, primary carcinoma of the ureter is very uncommon. Recent systematic works on surgery and on tumors contain no mention of carcinoma of the ureter. Indeed, the entire list of primary tumors of the ureter described in the literature is very short.

Lebert¹ describes a polypoid fibroma; Thornton,² a papillary fibroma, upon which a calculus was situated; Neelsen,³ a typical papilloma of the upper part of one branch of a partially reduplicated ureter causing a large hydronephrosis of the corresponding half of the kidney. Chian⁴ records a so-called cholesteatoma of the ureter, and Ribbert,⁵ a myosarcoma. Orth⁶ credits Litten⁷ and Hartman⁸ with having observed carcinoma of the ureter. Wising and Blix⁹ describe a case of primary carcinoma of the right ureter with secondary tumors in the mesenteric glands, the rectum and the liver, with hydronephrosis, in a woman 41 years old, whose urine did not contain anything abnormal. There was a hydronephrosis containing 1,000 grams of fluid. The upper 12 cm. of the ureter was spirally twisted, hard and thick, converted into a solid string the size of the little finger. On the cut surface there was no lumen, but in place of it a loose, yellowish gray disintegrating neoplasm. The wall of the rectum was the seat of multiple, submucous nodules due to extension from the metastasis in the retroperitoneal glands. The structure was that of a medullary carcinoma. Hedenuis¹⁰ describes hazel- and walnut-sized carcinomatous nodules in the mucous membrane of the pelvis and the ureter which were situated in the mucous membrane and pronounced by Hedenuis to be a primary carcinoma.

The following case concerns a married woman 50 years old, who had been in fair health until eight months before death, at which time she became aware of some pain about the right hip which was regarded as rheumatic. The pain gradually increased and soon the right lower extremity became swollen, and a swelling appeared in the right inguinal region. There was no history of any injury. Examination about one month before death showed marked emaciation, the heart and lungs apparently normal. Filling the lower right quadrant of the abdomen was a soft mass which seemed connected with the right ilium; the mass had

an irregular outline, and in the vagina it could be felt that the uterus was pushed to the left. The urine was normal, sp. gr. 1015. Death from exhaustion about eight months after the first painful symptoms appeared and after being bedridden for three months. The clinical diagnosis was osteosarcoma of the pelvis.

Anatomic Diagnosis.—Tumor of the pelvis involving the right ureter; hydronephrosis and atrophy of the right kidney; atrophy of the heart; pulmonary emphysema; chronic adhesive peritonitis; fibromyoma of the uterus.

The body is that of a senile woman, poorly nourished; rigor mortis present. The peritoneal cavity is empty; there is a retroperitoneal mass filling right half of pelvis and presenting on its pelvic aspect small, whitish, firm excrescences; the cecum is adherent to the tumor mass by means of firm, fibrous bands. The pleural cavities are empty and free from adhesions. The pericardial cavity is empty; the pericardial layers are smooth. The heart weighs 210 grams; the endocardium is smooth except that there are some whitish areas in anterior mitral valve. The heart's flesh is brownish and of uniform, rather firm consistence. The coronaries are normal.

The aorta is quite smooth. The lungs are very spongy and light; they contain but a small amount of blood. The bronchial glands normal. The spleen weighs 110 grams; its capsule is nodular and thickened. The liver weighs 1,200 grams; it is brownish in color. The pancreas and the gastro-intestinal tract are normal. The uterus contains a walnut-sized, submucous fibromyoma attached to the posterior wall of the fundus by a rather slender pedicle.

The tubes and ovaries are normal, the ovaries being small. The vagina is normal. The adrenals are normal.

The left kidney weighs 140 grams; the capsule is free, the surface smooth, the consistence firm; the cortical markings not distinct. The right kidney is not present as such; in its place is a cystic cavity containing about 800 c.cm. of a slightly turbid, grayish, thick fluid; the walls of this cavity, whose inner surface is smooth, are quite thin and directly continuous with the post-peritoneal tumor mass about to be described. The tumor appears to spring from the inner surface of the right ilium. It forms an irregular mass about the size of a child's head. On the cut surface it is whitish-gray in color; its consistence is soft and it contains numerous, small irregularly shaped cavities, filled with creamy semi-solid material. The ureter can not be identified at the upper limit of the tumor. A probe, passed upward from the opening in the bladder, becomes arrested about 2.5 cm. above. Careful dissection shows the ureter to be entirely lost in the tumor tissue. Upon removal of the tumor it is found that the inner surface of the ilium is eroded. The retroperitoneal glands are not enlarged.

Microscopic examination shows the structure of the tumor to be that of a typical medullary carcinoma. Throughout the section are large and small islands and districts of epithelial cells imbedded in a connective tissue stroma, which is composed of loosely arranged fibrillated connective tissue with but very few vessels. Only the smaller masses of epithelial cells are free from degenerative changes. The larger carcinomatous districts show a granular disintegration in their center, which might in some instances be mistaken for epithelial pearls; in many places the degenerative necrosis is very extensive and results in

¹⁰ Upsala Läkarförenings Föhr., Bd. 13, H. 1, quoted by Wising and Blix, loc. cit.

the formation of small cavities surrounded by a narrow zone of epithelial cells. The epithelial cells in the smaller, recent nests show innumerable, poorly preserved (twenty-four hours, post-mortem) karyomitic figures. The nuclei are rich in chromatin. The general characters of the cells in these recent districts of proliferation are those of the transitional epithelium of the ureter and the bladder, the cells varying greatly in their form, being oval, spindle- and club-shaped, and their nuclei polymorphous and often lobulated.

The reasons for regarding this carcinoma as originating in the ureter are the following:

1. The location—there being no other archiblastic structure in the vicinity than the ureteral lining—and the direct involvement of the ureter in the tumor, the larger part of the canal being entirely lost in the tumor mass, the hydronephrosis and complete atrophy of the kidney being due to complete destruction and closure of the lumen of the ureter.

2. The marked similarity of the epithelial cells of the tumor to the cells lining the ureter, the transitional character of the latter being well preserved in the tumor.

3. The absence of carcinoma elsewhere and the voluminous size of the primary retroperitoneal growth.

It is important to note that in carcinoma as well as other tumors of the ureter, occlusion of the lumen of the latter and consecutive hydronephrosis with atrophy of the kidney seem to occur quite regularly, as far as can be concluded from the few cases now at hand.

The thorough and systematic study of early carcinoma of the ureter, the earlier the better, would throw needed light upon the more exact origin and development of this rare, but interesting form of malignant epithelial tumor.

DISCUSSION.

DR. LE COUNT—I think there can well be added to the reasons that Dr. Hektoen cites for regarding the carcinoma of the ureter as primary, because of the fact that there is nothing else in that region that could give rise to the peculiar neoplasm the sections of which we see under the microscope.

BRIEF HISTORY OF A SUIT FOR DAMAGES FOR MALPRACTICE.

BY W. H. SHARP, M.D.

PARKERSBURG, W. VA.

At the last term of the circuit court of Wood County, W. Va., was tried a suit for damages for malpractice in the treatment of a patient suffering from an ovarian cyst, which case attracted much attention in our medical and legal circles, as well as in our community. The plaintiff was the husband of the deceased patient, bringing suit as administrator in behalf of her estate for benefit of her children. The defendants were Drs. T. A. Harris and W. C. Keever of Parkersburg and A. T. Keever of Belleville, Wood County, W. Va. The surgical history of the case is as follows:

Mrs. T., living eight miles from Belleville and twenty-five from Parkersburg, was a patient of Dr. Deem, a physician practicing in that neighborhood. She had an ovarian cyst, which Dr. Deem had tapped twice; the last time was about January 1. Her condition became worse. At neither time had tapping emptied the cyst. He then had Dr. A. S. Keever of Belleville called in counsel. Dr. Keever found her in a critical condition, too ill from septic infection to be moved and unable to lie down. It was evident that

if not speedily relieved she would soon die. Dr. Deem told him that she was not pregnant. It was agreed between her father and Dr. Keever that he bring Drs. Harris and W. C. Keever of Parkersburg to operate. This was on January 15. On the 17th they met at the house, Dr. Deem also meeting them. Dr. Harris explained to the father the desperate character of the case, owing to the condition of patient, who was evidently suffering from septic infection probably due to priorappings.

These surgeons had had considerable experience in abdominal surgery. On examining patient they found that she was four or five months pregnant, and it was evident that the fetus was dead and the uterus was trying to expell it. It then appeared that Dr. Deem, for purposes of diagnosis, had introduced a sound at prior visits. The os was so dilated and soft and flaccid that two fingers could be easily introduced. The waters were drained off and the uterus pressed down very low into the pelvis, so that the os was visible on separating the labia. The patient also had an ovarian cyst completely filling the abdomen. They decided to remove the fetus first without anesthesia; this was an unexpected complication for which they were not prepared. Turning the fetus and drawing upon one leg, that limb separated at the hip; the other leg did the same; then the arm at the shoulder, the fetus was so macerated. Dr. Harris attempted to extract by traction with a tenaculum buried in tissues of scalp; but it tore out like from wet paper. A blunt hook was then improvised from a piece of fence wire found upon the premises, which Dr. Keever prepared, disinfected, and removed rest of fetus. The placenta being adherent, was left for removal the next day. The patient's condition being as good as when they began, she was prepared; and under chloroform anesthesia abdominal section was made with strict antiseptic precautions. A twenty-eight pound ovarian multilocular cyst was removed. There had been leakage from the opening made by the last tapping. She rallied well and was left by Drs. Harris and Dr. W. C. Keever, the operators, in care of Drs. A. S. Keever and Deem. Dr. Keever was to remove the placenta the next day, and disinfect uterus, which was done. Thirty-eight hours after operation patient died, probably of exhaustion and septicemia present before operation.

Then followed the legal side of this case. Her husband brought suit as administrator against Dr. Harris and Dr. Keever for causing her death by their wrongful act and neglect under sections 5 and 6 of chapter 163 of code of W. Va., damages asked being \$10,000. The plaintiff's witnesses were Dr. Deem, the wife's father, a neighbor woman and a neighbor man. The husband because he was administrator was not put on the stand, in order to keep the defendants from testifying. They testified that the child was living and was destroyed by defendants; that the wire used was rusty and not disinfected; that the defendants incised the mouth of womb in removing fetus; that fluid from the cyst was allowed to escape into the abdominal cavity; that in this way the operation was unskillfully done. The plaintiff claimed that the operation for removal of tumor should have been postponed until another day, until she had recovered from the capital operation of removing the fetus, and that the wife died from shock and lymphatic septicemia resulting from the "wrongful, neglectful and unskillful" performance of the operation.

The defendant surgeons were now offered as wit-

nesses to show: 1. the condition of the patient on the 15th and again the 17th, the day of the operation; 2. what they stated in her presence to her father regarding the necessity for the operation and chances of life with and without it, and his instructions to them; 3. what they did and all the facts concerning the operation; 4. what took place while the patient was under the influence of anesthesia; 5, to contradict the statements made by witnesses who were present at the operation. The plaintiff objected to the witnesses testifying as to these matters, because they were prohibited by section 23, chapter 130 of the code of West Virginia, from testifying in regard to any personal transaction or communication had with the deceased. After hearing argument and examining authorities and decisions, the court held that this was a personal transaction and that the defendant could not testify as to anything said by them, done by them or others in her presence, or as to condition of the patient as they found it, or anything occurring when she was present. "That death had sealed the lips of one party to this transaction, and the law sealed the lips of the other parties to all communications, conditions and deeds done, to which she living could testify." No precisely similar case was cited, or indeed found. The defendants' counsel argued that this surgical operation was not a "personal transaction" within the meaning and spirit of the law. But the court so held it to be. Consequently it was a very one-sided case. The defendants could not testify that the patient's condition was desperate; that the fetus was dead and macerated; that the uterus was not incised; that the wire was properly prepared; that her condition was as good after the removal of the fetus as before; or that no fluid escaped into the abdomen from the tumor. Indeed, Dr. A. S. Keever was forbidden to tell her condition on the 15th, the day of his first visit. All hypothetical questions to the expert physicians and surgeons had to be framed upon the evidence given by Dr. Deem and his fellow witnesses. Negatives had to be proved by saying that the affirmatives could not be so, and even then it was hard to arrange a question that would bring out a denial of the plaintiff's claim or evidence that could suit the judge's decision. The jury disagreed, being ten for damages and two for acquittal. It appears that several of the States have laws similar to ours. I remember notably that New York, Virginia and Illinois were cited. In all probability the case will come up at a future term of court.

If such a decision was to hold in all the States having this law or similar laws in their codes, it behooves physicians and surgeons to have disinterested and intelligent witnesses with them in all cases where the patient may die, as suits for damages need not be confined to surgical operations, but can be extended to medical and obstetrical cases, and given the favorable opportunity and witnesses the administrator could make an estate for the family of the dead patient, because the defendant would not be allowed to contradict the very statements upon which the plaintiff's case stands.

Mr. W. G. Peterkin, in an article in the *Bar*, relating the legal points of this case and from whose article I have quoted, says: "It stands to reason that in many desperate cases an operation will save life or hasten death. Evidence tending to show the latter fact without explanation or palliation would of necessity raise an unfavorable inference against the surgeons in

the minds of many jurors. Doctors can not without the greatest professional impropriety take witnesses for their own protection, especially in cases of a delicate nature. Every law, humanitarian and professional, forbids their refusing to relieve a desperate case and yet the more desperate the greater their danger. From the nature of the case they can not get the 'transaction' into shape of a writing. They can not go upon the stand and contradict false statements made as to what occurred at the time of the operation, that being part of the 'transaction,' but must face without explanation or contradiction the testimony of persons who will in many cases be totally ignorant of every principle of surgery and medicine, and whose conclusions are drawn solely from the ultimate life or death of the patient, when often death would follow inaction, and the patient finally dies not from, but absolutely in spite of, the operation."

Indeed, the chief counsel for the plaintiff argued that rather than have attempted to save this patient under the desperate conditions as claimed by the defense, she should have been left alone to die in peace.

On the part of the medical profession some effort will be made to unite the profession in an endeavor to have the Legislature modify the law, so that we may be protected from such decisions. The employes of a corporation can testify in such a suit, although they are the only representatives of the corporation present and probably responsible for the neglect. Had it been a criminal charge for manslaughter in causing her death or of criminal abortion the defendants could testify; as a legal friend said to me: "The doctor had better get himself indicted on the criminal charge as the easier to meet."

TORTICOLLIS AND ADENOID GROWTHS.

Read by Title before the American Laryngological, Rhinological and Otological Society at its Second Annual Meeting, held at New York, April 17, 1896.

BY J. E. SCHADLE, M.D.

ST. PAUL, MINN.

Hypertrophied lymphoid tissue at the vault of the pharynx, according to my research on the subject, has not heretofore been recognized in its pathologic relation to torticollis.

That an intimate relationship does exist is, I believe, quite clearly demonstrated by the clinical features and satisfactory results obtained in the following dispensary case sent to me by my colleague, Dr. Gillette. In his note of reference Dr. Gillette says: "I refer this case to you, as I think it bears some resemblance to one which I sent you some months ago, and upon which you operated. The boy is about 3 years old and was under my care some three months since for rickets, from which he had a good recovery. The mother informs me that about six weeks ago he seemed to be suffering from a 'slight cold,' and she observed that he did not hold his head straight. A physician was called and ordered hot applications to the 'contracted side of the neck;' from that time to the present, she has continued this treatment and other domestic remedies with no improvement. It is, as you notice, a well-marked case of torticollis. The child has no fever, or any constitutional symptoms. The head is held perfectly rigid by the tonic spasm of the sterno-cleido-mastoid muscle, which is the only muscle seemingly involved. I find no evidence of nervous trouble, caries of the vertebrae or scoliosis,

neither is there any history or manifestation of injury; all I discover is the wry-neck and the hypertrophied tonsils. If you find any disease of the nose or throat, please treat it and have the child referred to me for observation."

The child presented the usual physical signs of obstructed nose-breathing. On examination of the throat I observed the tonsils congested and swollen. A rhinoscopic examination of the retro-nasal space not being practicable, I explored the cavity with the index finger and found it occupied by a mass of hypertrophied lymphoid tissue. Curettement was resorted to and the adenoid vegetations were thoroughly removed.

The case progressed favorably without any untoward symptoms manifesting themselves. On the second day after the operation the patient was seen and showed improved respiration and total disappearance of the wry-neck. It is now three months since the case was dismissed, and up to this time no symptom of a reappearance of the torticollis has been noticed. The general health has improved most markedly.

It may be well to state that the other case referred to in Dr. Gillette's letter was operated upon two years ago. The boy was 8 years old and suffered from wry-neck from infancy in a marked degree. It was a typical case of obstructed nasal respiration, produced by the presence of adenoid vegetations and chronic hypertrophy of the faucial tonsils. The three tonsils (pharyngeal and faucial) were removed. The boy has been well ever since.

THE BEST METHODS OF TEACHING.

Abstracts of papers read at the meeting of the American Academy of Medicine, Atlanta, Ga., May 4, 1896.

THE BEST METHOD TO TEACH SURGERY.

BY PROFESSOR J. S. WRIGHT, M.D., BROOKLYN, N.Y.

In teaching surgery the following points are important: The teacher must have large clinical observation as well as operative experience; he must be rapid in thought and have a good clear judgment. His knowledge must be well digested and at hand, so that he can call upon the storehouse of his practical knowledge for whatever he needs at any and all times and in every emergency. Though he may be influenced by the suggestions of his contemporaries he must rely, in the end, solely upon himself, since he alone is responsible.

In many ways a teacher is born, not made; that is, he has the teaching diathesis. He sees clearly the important facts of a case, knows how to present them to the medical student, distinctly, succinctly, impressively, for it must ever happen that the teacher who does not know a fact can not teach it to someone else.

It is of much importance to have the teacher familiar with descriptive, living and morbid anatomy. Descriptive anatomy is the groundwork; living anatomy is what we find it in the living body, and is no less essential; morbid anatomy is highly essential, as it is a deviation from the normal structure.

In theory at least the learner ought to be informed as far as possible in regard to these different kinds of anatomy. The teacher of surgery ought not to be required to spend time, at least to any extent, with the subject of anatomy, unless by way of supplementing the knowledge which the student already has. He may, however, deal with anatomy from the surgeon's standpoint.

The fact that a student ought to be prepared for receiving instruction in practical surgery is being recognized more and more. The most consummate teacher can not make a surgeon out of a young man who is unlettered, untaught, unprepared. On the other hand, we have seen that a surgeon may be developed, be his teacher ever so incompetent.

Recognizing the fact that there must be didactic teaching of what is purely elementary, that the principles of surgery must be taught by books and lectures, it remains to be said that the only really practical surgical teaching is at the bedside or in the operating room. The surgical disease must be studied at the bedside of the patient and its features in all their relations must there be learned. In the operating room the student must learn the steps and processes of operations. These he must see and assist in, and thus become familiar with the technique of surgical procedures. He must learn to apply his anatomic knowledge to the process of saving life. Let him follow each case to the end of its clinical history, whatever that may be.

The question is a search for practical truth, and this the student can get only in the presence of the operative process. An operation may be carried out upon a definite plan, or that plan may have to be changed. That is, the student must learn that the plan of an operation, however well arranged beforehand, may have to be changed, step by step, as the work proceeds. By actual observation he must try to learn the art of the surgeon. There is such a thing as doing too much; there is such a thing as doing too little; the thing to do is just enough. There is such a thing as taking too much time; there is such a thing as taking too little time; let the time be neither too great or too small. In all cases when the operation is completed let the surgeon stop work and let the student know why he does so. The student must be taught these steps, these processes, these limitations, and these results.

There are some points upon which I wish to lay stress: The time of medical study is too short. The entire field of medical education can not be traversed in three years. The time ought to be extended to four years, perhaps even five years ought to be taken for this important work. It is true that a general movement is now going on in the direction of taking more time to prepare young men for the practice of medicine and surgery. As things are now, if we take the average student, he either fails or may break down hopelessly during his course of study or at the close of his examination. This statement is not overdrawn if we keep the student up to the highest standard of excellence. There is a limit to the student's capacity for work. He must be given time to lay the foundation for a good preparation to enter upon his life's work.

The practice of antisepsis is no doubt difficult to carry out. It is, as a matter of fact, difficult to teach because it is not easy for the student to learn. It is perhaps easy enough for a student to acquire a knowledge of antisepsis, but the difficulty lies in practicing the art of antiseptic surgery, in which good results can be obtained by repeated trials only.

It is true that medicine is ever progressive and surgery is ever progressive, since development is the inherent law of vitality alike for science and art, and with the best of us when years of practice leave room for progress, when our most advanced students are

compelled to repeat the words of Michael Angelo, spoken when an old man: "Still I am learning." Why do we expect so much of a young man who has spent only a few years in the study of a science so comprehensive, of an art so difficult as surgery?

The standard of qualification and attainment should conform to an average capacity and a reasonable time for study. It does not comport with good teaching to break a man down in health in order to be sure that he has learned how to restore patients to a sound physical condition. Has the young man learned to study? Has he learned to think? Is he prepared to investigate and treat the diseases and injuries that he will meet most frequently in practice? Has he become familiar with sound and safe principles of practice?

Finally, lest the student giving his attention to rare and intricate diseases and injuries becomes a failure, lest he, with all his ambition, either through his own or his teacher's negligence fall short of a true success, let him ever repeat and remember words that might well be spoken by a man nearing the end of his career:

Had I but searched for truth with half
The zeal I sought for fame,
I had been wiser in my day
And left a loftier name.

THE BEST METHOD TO TEACH OBSTETRICS.

BY J. C. EDGAR, A.M., M.D., NEW YORK.

The fault of the earlier teaching of obstetrics in the United States was that the science was taught and the art neglected; this is, however, changing with the increased length of the medical course and the greater facilities, but not as rapidly as the improvement of teaching of the other branches. The best method of teaching is rather a system including several methods. A pre-knowledge of anatomy and physiology is necessary. Experience has taught that the following plan and arrangement of topics is best adapted to secure the ends sought after:

1. Systematic bi- or tri-weekly recitations during the second college year.

2. Demonstrations and manikin work; attendance upon obstetric clinics; and laboratory work during the third collegiate year.

3. A resident service in a maternity hospital, which shall include, (a) the examination of pregnancy under competent instructors; the actual confinement of patients by the student himself, under rigid supervision; (b) "ward" or in-door service; and (c) "out-door" or polyclinic service; (d) the attendance on the obstetric clinics of the hospital; (e) theoretic lectures (illustrative in character), and (f) recitations subsequently upon the previous practical work performed by the student.

4. Theoretic lectures (illustrative in character) upon advanced obstetrics.

A recitation has been found to be superior to the lecture, but the instructor must see that the text-book is supplemented by illustrations and the application, during recitation, of the subject of the recitation. For this purpose there should be plenty of blackboard space, pelvis entire and in section, diagram, models, wet and dry preparations and instruments. He should also carefully prearrange the whole course. In the recitation hour each member of the class, which should not include more than about twenty students, should be examined in some way. To this end some should be sent to the blackboard, some to examine specimens,

some to use the models, while some are being quizzed.

The classes for this division should not exceed thirty, and it is desirable that the instructor should be practically a demonstrator in a laboratory properly equipped for obstetric work. Bi-weekly or tri-weekly meetings for six or eight weeks will suffice for manikin work, which will include a review of the theoretic part already gone over. And here too each student is to be kept busy for most of the hour and the models, etc., should be more abundant than for the previous course, care being taken to so use the models as to prepare for the practical work afterward, and they should be occasionally supplemented by a demonstration on the living subject. At this stage it is well to have the student attend several clinics and if possible watch the delivery of several children.

The author believes that the student should not only witness deliveries, but should actually confine women and care for them and the child afterward; always under the supervision of an instructor. This is most valuable to the student, enabling him to observe the application of the knowledge he has acquired, and also to apply it himself. At first his service is rather passive, to observe and be present; and in the examination and diagnosis of pregnancy. Then, under great precautions, he is permitted to examine several cases in labor in the wards and then he is allowed to care during the entire confinement. After this he can be assigned to the care of women at their own homes. With a properly equipped operating room and amphitheater an entire clinic can be made of any case of labor in the maternity.

He expressed deep conviction that obstetrics should not be considered a specialty, but a department of medicine and surgery.

In all recitations, etc., the instructor should seek not only to render a service to his pupil but to medicine as well, by rising to something higher than the mere perfunctory performance of his assigned duties. No part of any subject can be properly understood unless it is studied in its relation to the whole; hence the relationship to the other departments should be made clear.

The day is past when midwifery does not receive equal attention with the rest of medicine, but because there was once such a time the student's attention should be called to it in order that in his future career he may not fall into the error of regarding midwifery as a thing apart from general medicine. It may not be amiss to cite a few instances demonstrating this; the toxemia of pregnancy is still toxemia, so with the transient glycosuria, with jaundice, cardiac hypertrophy, thrombosis, etc. These conditions in the pregnant women are more apt to teach us the etiology of these conditions than studies in the deadhouse. While gynecology may be thought to be a specialty, not so obstetrics.

This argument may appear at first sight a digression from the subject, but reflection will show not only the justice but the necessity of its introduction. His student career is the time when the physician is most impressionable and when facts are most readily brought home and fixed in his mind.

SOME RESULTS OF MEDICAL LEGISLATION.

BY J. M'P. SCOTT, A.M., M.D., HAGERSTOWN, MD.

The spirit of all law should avoid inequality and injustice, and in the manifestation of this principle the power of the State has been exercised to regulate

the various instrumentalities and institutions which are operating on the body politic, including the State regulation of the practice of medicine.

Historically, the right to certify to fitness to practice has always been claimed by the State through its law-makers. By their incorporation, medical colleges are creations of the State; the wisdom, or lack of it, in granting charters does not invalidate the statement. Because of this, the State would have the right to exercise control over the courses, etc., of the college. There are difficulties in this, and many States have obviated them by the adoption of methods to review their work in the individual by the examining and licensing boards.

This has been made a necessity by the departure from the high ideals belonging to the profession and the lowering of the standard, and that, too, by the very persons intrusted by the State with the power to confer diplomas. Four years' service upon a State examining board has forced this conclusion upon the author, and in proof of it a number of answers to the questions of the Maryland Board were quoted.

The Maryland Board endeavors only to present fair questions to determine whether the applicant may be safely permitted to enter upon the practice of medicine; endeavoring to be just to the medical colleges and fair to the applicant. The general acquiescence in the findings of the Board leads it to believe that its efforts have been appreciated.

The work of an examining board enables it to make suggestions that may aid the colleges in their work. The answers quoted above show the necessity of adopting a more thorough course and more critical examinations. It is gratifying to note that the colleges are moving in this direction; the contrast between the papers submitted now with those submitted at the earlier meetings is conspicuous.

The lack of academic training has been painfully manifest in many papers, so that the proper preparatory training should be demanded as essential to matriculation in all medical colleges.

SOCIETY PROCEEDINGS.

The American Surgical Association.

Annual Meeting, held at the Detroit College of Medicine, Detroit, Mich., May 26, 27 and 28, 1896.

FIRST DAY—MORNING SESSION.

The President of the Association, DR. LOUIS McLANE TIFANY, of Baltimore, called the meeting to order and read an address entitled

THE OPERATIVE TREATMENT OF TRIFACIAL NEURALGIA,

in which he stated that forty-five operators had participated in the hundred cases reported, of which number twenty-four had each operated upon one case only. He also mentioned that there was diminished sensation in these cases, and lessened lachrymation. He considered the curving of the tongue due to atrophy of the muscles but did not understand why the perception of heat and cold should be interfered with. As to tying the carotids, Dr. Park of Buffalo had successfully done this in two cases.

DR. S. J. MIXTER, of Boston, read a short paper in discussion of this subject, which was then thrown open for general discussion.

DR. W. W. KEEN, of Philadelphia, was very much disappointed to learn that the mortality of operations for the relief of trifacial neuralgia was 10 per cent. He had two deaths out of nine cases, one of which was due to sepsis and was avoidable. He explained the high mortality as being due, in his opinion, to the fact that the operations had been done by so many different operators, and thought that special operations should be reserved for those who have had some special training. In three

of the nine cases mentioned, trouble was experienced with the cornea, but in no case was the eye lost. The following is Dr. Keen's method of dealing with corneal ulcer: Sew the lids together at the margin so as to prevent the opening of the eye, take a circular piece of rubber plaster, cut out a circular hole in the center a little smaller than a watch glass, insert the watch glass in the hole thus made and place this shield over the eye, the non-adhesive surface being next to the patient's eye. Although the rubber plaster does not absolutely occlude the whole space, yet the inside of the watch glass is always moist.

DR. J. EWING MEARS, of Philadelphia, asked whether the President was clear in his own mind that the lesion exists in the Gasserian ganglion. If his experience with the operation upon the Gasserian ganglion demonstrates that the relief from pain is permanent, Dr. Mears felt that the real lesion had been discovered.

DR. GEORGE RYERSON FOWLER, stated that in one of his cases there was a recurrence of pain, although he was absolutely certain that he had removed the ganglion. Postmortem showed the existence of a neuroma upon the stump in that portion which occupied the foramen rotundum. He fully agreed with Dr. Keen as to the necessity of keeping the eye protected and mentioned an illustrative case. Concerning the sclerotic changes in the vessels, it may be that these are at the root of the pathology of these cases. Dr. Fowler referred to a case operated upon by Dr. Morton of Philadelphia, in which Meckel's ganglion was positively removed and yet the pain returned with all its former violence in less than two years, when ligation of the common carotid gave the man permanent relief. The author mentioned other cases in which ligation of the carotid had produced excellent results, and in one of which there was a deviation of the tongue toward the side operated upon. In this case the patient was unable to straighten the tongue. He referred to one case which died during an epidemic of sepsis, and stated that he saw no reason why there should not be an epidemic of sepsis as well as of smallpox and scarlet fever.

DR. JOHN PARMENTER, of Buffalo, mentioned the case of an elderly woman who had facial neuralgia, and also a small aneurysm of the external carotid, in whom ligation of the common carotid afforded complete recovery. He also cited a case in which he did an operation successfully on a man who had been subjected to three previous operations.

DR. H. S. WEEKS, of Portland, doubted if a surgeon was justified in resorting to intra-cranial operations before an extra-cranial had been done, in view of the large mortality. His plan is to trephine through the ramus of the jaw, seize the inferior dental nerve and pull it away, as he considers this method much better than cutting.

DR. N. P. DANDRIDGE, of Cincinnati, cited a case on which he had operated two and a half years ago, since which time the man had been relieved from pain, but there was marked deformity of the face on account of atrophy of the muscles. There was also a small sinus leading down to dead bone.

DR. CHRISTIAN FENGER, of Chicago, preferred the extra-cranial operation, as he considered it less dangerous. He called attention to the fact that the mortality from ligation of the common carotid was 18 per cent.

DR. JOSEPH RANSOHOFF, of Cincinnati, did not think 10 per cent. a very high mortality under all circumstances, and said if all the cases were included it would be nearer 50 per cent. In his opinion the lesion is not located in the Gasserian ganglion, but is a central affection.

DR. ROBERT ABBE, of New York, said the members should not be daunted by a mortality of 10 per cent., as in the next hundred cases it would be much less. In his opinion preference should be given to an anterior operation in the first place. Now that we know what to steer clear of, with the improvement in asepsis and the avoidance of operating on old people the mortality should be considerably lessened.

DR. W. W. KEEN said he had omitted to mention two methods of medical treatment which had been of great service; one recently suggested by Dr. Dana of New York, that of giving massive doses of strychnia, and the other was suggested by Esmarch, who has spoken of the value of purgatives.

DR. MAURICE H. RICHARDSON, of Boston, believed that attacking the ganglion should be done as a last resort, especially in old people and those who were unable to stand so formidable an operation as intra-cranial neurectomy. In many cases a simple operation would give considerable relief.

DR. FOWLER explained that the mortality of 18 per cent. in ligations of the carotids, included cases of aneurysm, gunshot wounds, etc. In fifty-two cases, where the vessels were not affected by disease nor complicated by carcinomatous tumors, the mortality was less than 5 per cent.

DR. P. S. CONNER, of Cincinnati, said the two most important points were the cause of the neuralgia and the results of operative interference. In a certain proportion of cases the exemption from pain ranged from three months to three years, while in another proportion the exemption was scarcely worth mentioning, as the pain returned immediately after the operation. In some cases the loss of blood during the operation and the shock from the operation had caused periods of freedom from pain. The propriety of the operation had been established, as a man would rather take forty-nine chances out of fifty to get relief.

DR. T. A. MCGRAW, of Detroit, was of the opinion that sufficient investigation had not been made of the possibility of the neuralgic conditions being due as well to motor as to sensory nerves, and stated that he was not at all sure that a division of some of the motor nerves might not be a great benefit.

DR. RICHARDSON stated that this operation had been performed and resulted in considerable facial deformity, but no relief of the neuralgia.

DR. S. J. MIXTER mentioned two cases in which merely reopening of the old intracranial wound had afforded some relief.

AFTERNOON SESSION.

DR. ALBERT VANDER VEER, of Albany, presented a paper on TUBERCULOSIS OF THE FEMALE GENITAL ORGANS (INCLUDING TUBERCULOSIS OF THE KIDNEY).

Dr. Vander Veer stated that this subject had been neglected until recent years, and that the modern ideas and progress depended upon careful histologic and bacteriologic examinations. Tuberculosis of the female pelvic viscera was not limited to any age, the extreme limits being ten weeks and eighty-three years. External genital lesions might be confounded with tuberculosis. Heredity was important as suggesting tubercular possibilities. Tuberculosis was extremely rare in the external genitals, but by no means infrequent in the uterus. Tuberculosis of the uterus could be demonstrated by microscopic examination of the discharges and by curetting. Gonorrheal infection was often grafted upon tuberculosis. Sometimes infection took place through the fingers or the instrument or the semen. Tuberculosis originated in the tubes and infected the uterus and cervix. The uterus could be infected from without or within, and the infection was aided by a lacerated cervix, pelvic peritonitis, trauma, etc. The symptoms were local irritation, a pea-sized wart near the vaginal outlet, a discharge from the uterus, etc. The differentiation between the ulcers of syphilis and epithelioma depended on age, history, local appearances, etc. Tuberculosis of the cervix might be mistaken for cancer. Many vaginal cases were infected from the tubes, and tubercular peritonitis might infect the vagina and tubes. The author mentioned several cases illustrative of the points mentioned.

With regard to tuberculosis of the kidney, there were two forms: 1, miliary tuberculosis; and 2, caseous or true tuberculosis. The author gave the details of one or two cases and referred at some length to Kelly's nephro-ureterectomy.

TUBERCULAR PERITONITIS.

DR. ROBERT ABBE, of New York, in reviewing this interesting subject, thought it gave a fairer understanding of the miliary appearances of the disease if we viewed it from the standpoint of the bacillus rather than, as others have done, from the gross appearance, which has led to the division into the ascitic, the dry and the caseating forms. A sudden tubercular eruption into the peritoneal cavity may be as acute in symptoms and duration as peritonitis from other causes. A slower outbreak may result in ascitic distension in three or four weeks, and a less virulent bacillus action may occupy months in inducing ascites and wasting. In other cases, possibly due to the route of invasion (penetration through lymphatics communicating mucous and peritoneal serous coats or by follicular ulcers allowing tuberculous milk to be the medium of infection) a dry or adhesive form follows in which hectic and rapid wasting result. Again, the bacillus produces an outpouring of thick lymph and flocculent serum, which rapidly becomes purulent, producing unsymmetrical cakes of thickened omentum, matted coils and encapsulated purulent collections. The bacillus product rapidly caseates and ulcerating fistulae may result. All phases of the disease may be regarded as representing the life history of the bacillus and its products. Tubercular peritonitis may be, and in the earlier stages often is, the only site of tubercle deposit in the patient, hence, if overcome here, a practical cure often follows. Even when other phases of infection (pleural, intestinal, bronchial) are seen, an operative cure of the peritonitis has often been followed by general recovery. The mode of entrance of the

bacillus is directly through the intestinal wall or through ulcerating appendicitis or tubal or ovarian tuberculosis, or through the blood. The claims of a few recent authors to having cured tubercular peritonitis by medical treatment were reviewed and credited.

The unquestioned cure of true tuberculous peritonitis by laparotomy was proved by two classes of cases, those who have long survived operation, and those who have come to autopsy long afterward, and have been found free from tubercles that studded the peritoneum at the time of operation. Experimental proof in animals corroborates also operation by simple laparotomy and evacuation of the ascites; closing the dry abdomen is credited with a large number of cures. Irrigation with warm salt solution is advocated by preference. Camphor-naphthol application, as used by Rendu, is advised for bad cases.

Dr. Abbe reviewed many interesting and illustrative cases in speaking of direct medication. The many theories advanced to account for the surprising cures were carefully considered, and it was said in conclusion that "the theory that is sustained by most facts is that based on the life history of the bacillus and the capacity of the animal economy, not only to suppress the activity of the organism by encapsulating it, but to remove it by absorption. The proper opportunity for conquests is not afforded in the presence of ascitic fluid, which acts as a veritable culture bouillon and by its fluidity aids dissemination. When, however, the peritoneum has been aroused by congestion, which follows evacuation, and a reactionary inflammation is set up, engendering cell hyperplasia, the intruder is walled in and retrograde degeneration sets in."

INTRA-THORACIC TUBERCULOSIS,

by DR. GEO. RYERSON FOWLER, of Brooklyn. The author went into the historic part of the disease at great length, and devoted considerable attention to the surgical treatment of pleuritis and empyema. Of all the organs in the human body the lungs are most frequently the seat of these affections. Inasmuch as there is no lung affection that can not be complicated by tuberculosis, it follows that pleural affections are most frequently tuberculous in character. Few patients who have suffered from pleurisy escape tuberculosis, and this fact increases the importance of the surgery of pleuritic affections in their relation to tuberculosis.

The author gave a brief discussion of the effects of the presence of the pleuritic effusion upon the progress of tubercular disease of the pulmonary structure. The view formerly held that the activity of the circulation in the lung tissue constituted a trustworthy means of protection against the occurrence of tubercular infection of the respiratory organs was combatted and reference was made to the observations of Laennec, who, in the early history, stated that stasis was incompatible with the progress of pulmonary tubercular affections, and Bier's observations, supported by those of Miller, in the treatment of tubercular joint disease by means of a constricting bandage, were held to confirm the views of Laennec in this particular. Note was taken of the fact that in any pleuritic affection, even when due without doubt to tubercular affection, the effusion is found to be serum. The suggestion follows that this effusion possesses some resisting influence over the development of the tubercle bacillus, while it undoubtedly forms a favorable culture medium for other organisms. The application and technique of exploratory puncture or thoracentesis, incision and drainage and Koenig's operation, the resection of a portion of rib, were gone into quite extensively. This was followed by a consideration of the operation of thoracoplasty and its indication. Schede's operation for extensive resection of the chest wall, including with the bony resection removal of the attached soft parts, namely, the intercostal muscles and thickened pleural membrane, was described. It was recommended that the edges of the incision should be approximated closely about the drainage tube and the dressing should be applied in such a manner that the tube passes through these. The drainage tube is then attached to a tube sufficiently long to lay over the side of the bed and touch the surface of a sublimate solution. When the patient can sit up the tube is fastened to a bottle at the waist, as suggested by Bulau, of Hamburg. By this method of drainage the patient is saved from the discomfort produced by soiled dressings.

The question of complications occurring in connection with thoracoplastic operations upon the chest wall, namely, pulmonary thrombosis, cerebral embolism, and the resulting paralysis, was alluded to.

The consensus of opinion at the present day seems to discountenance thoracotomy in tubercular patients, preference being given to repeated puncturing or at the most the method of permanent siphonage.

The question of the direct treatment of tubercular cavities was entered into quite extensively, and it was stated that some difficulty must necessarily be experienced in the selection of proper cases. In cases in which the disease had come to a standstill, any interference would be unjustifiable, for the reason that it is these cases that undergo cure by natural processes. In addition to limiting operations on tubercular cases to those that are circumscribed, the operation may be applied to certain cases of a doubtful nature which form at the expense of both pleura and lung, namely, pulmonary abscesses secondary to tubercular caries of the ribs. Three examples of this were quoted.

The operation of resection of the lung was discussed at some length, and attention was called to the fact that the pulmonary structure differs from all other structures in the body in its susceptibility to infection and its anatomic peculiarities.

The experiments of Glück, of Berlin, and Hans Schmidt upon the lower animals for resection of the lung were detailed, as also were those of Virondi, who produced localized tuberculosis in the lower animals.

DR. DEFOREST WILLARD, of Philadelphia, read a paper on
TUBERCULOSIS OF THE SUPERFICIAL GLANDS.

DR. WILLARD first detailed the method of tubercular infection of the lymph nodes. The route of entrance is usually by very slight abrasions or injury. Slight wounds are more liable to admit bacilli, as they arouse local resistance to a less degree than more severe injuries. The face and neck are especially common routes of entrance. The lymph glands act as filtration stations and often prove effective in overpowering the invading foes. They are likely to be successful in proportion to their amount of resistive force. An individual's resistive force may be lessened by hereditary impairment of cells or by the temporary condition of the tissues.

Local karyokinetic action may be successful, or if partially successful, caseation and absorption may occur with less resistive power, or if staphylococcus infection results suppuration follows. When once the glands have become infected, they are a perpetual menace to the general system and should be removed. Suppuration will sometimes effectually destroy all the invading bacilli, yet this is a slow and dangerous process, subjecting the individual to constant risks.

Infected glands should be removed if possible during the stage of duration. The removal of tubercular glands from the neck is frequently a most serious operation, provided connective infiltration is present, and especially if the chain of glands has dipped deep beneath the cervical vessels and nerves or has extended below the clavicle. These deep glands can only be safely removed by following the line of cleavage between the gland and the protection wall which has been partially thrown about it, each gland being cautiously shelled out. The jugular veins, the branches of the carotids and the pneumogastric and phrenic nerves should be carefully avoided. When a vein is injured immediate pressure with subsequent ligation or lateral suturing should be performed. If the phrenic or pneumogastric are injured they should be at once sutured with fine silk. Great care should be exercised to prevent the discharge of pus and caseating material upon the fresh wound; if such accident occurs the area should be thoroughly cleansed and disinfected. Temporary drainage is advisable when infection has occurred from such discharge; but in healthy operations with clean enucleation primary union without drainage can be secured.

In infection in the axilla the glands should be enucleated with the same care that is employed in the removal of carcinomatous nodule. The same rule holds good in regard to glands situated in other portions of the arm. In the groin many difficulties will be encountered, especially if the indurated glands extend deep about the femoral or saphenous veins. Secondary operations are advisable, if necessary. In cases that absolutely refuse operation, local and constitutional measures must be employed, including tuberculin and sero-therapy.

The author has more confidence in the local effects of iodine upon tubercular granulations than in iodoform. He has also had beneficial results from stimulation of cell growth by a mixture of aristol with nuclein or proto-nuclein, applied locally. Tubercularly infiltrated glands should not be allowed to remain and contaminate the general system.

Short papers on this discussion were read by Drs. J. McFadden Gaston, of Atlanta; Chas. B. Nancrede, of Ann Arbor; J. R. Weist, of Richmond, Ind., and G. W. Gay, of Boston.

SECOND DAY—MORNING SESSION.

DOES ADDITIONAL EXPERIENCE SHOW THAT CASTRATION IS A CURATIVE REMEDY IN THE TREATMENT OF HYPERTROPHY OF THE PROSTATE GLAND?

By DR. ALBERT T. CABOT, of Boston. He drew the following conclusions:

1. In the matter of mortality the operation of prostatectomy has a slight advantage over castration. It seems probable that with later statistics, reflecting the last improvements in the technique of prostatectomy, this advantage would be further increased.

2. Prostatectomy had the further advantage that it allows of a thorough examination of the bladder and of the discovery and correction of other conditions not before suspected. Stones are frequently removed in this way without adding to the gravity of the operation. In several reported cases of castrations the absence of improvement has led to the subsequent discovery of stones which have required other operations for their removal.

3. Prostatectomy has, on the other hand, the disadvantages that it confines the patient for a longer time, and that it is sometimes followed by a fistula. This occurred in one of the forty-two cases cited in this paper.

4. It is too early to know whether any permanent loss of vigor follows castration when done on old men. The nervous effects which sometimes immediately follow the operation suggest a suspicion that with the testes the system may lose some tonic effect exerted by those organs.

5. The functional results of the two operations seem at present to be as nearly equal as possible, and the tendency to relapse shows itself in about the same proportion of cases after either operation.

6. The reduction in the size of prostate after castration is largely due to a diminution of congestion. Later a degeneration and absorption of considerable portions of the gland may occur. The glandular elements are particularly affected by this atrophy.

7. Castration would seem to be especially efficacious in cases of large tense prostates when the obstruction is due to pressure of the lateral lobes upon the urethra.

8. Castration is of but little use in myomatous and fibrous prostates.

9. Prostatectomy has its especial field in the treatment of obstructing projections which act in a valvular way to close the urethra. There is, however, no form of prostatic obstruction which a skillful operator may not correct by prostatectomy.

10. Prostatectomy is then applicable to more cases than castration and is especially to be selected when an inflamed condition of the bladder makes drainage desirable.

DR. J. EWING MEARS, of Philadelphia, was very much struck with the mortality shown from the different operations. He was sorry to learn that no one had any information to offer concerning an operation suggested by himself as a substitute or castration, namely, ligation of the vas deferens.

DR. CHAS. B. NANCREDE, of Ann Arbor, said that as a result of his work with the operation of castration, he had been converted from a rather doubtful attitude towards the operation to a desire and willingness to do it again. He gave at some length the details of the case operated on by himself, which did very well after the operation, but the patient died in five or six weeks from an infection of his wound.

DR. L. P. PILCHER, said that from the statistics mentioned in Dr. Cabot's paper, it would seem that prostatectomy had a slight advantage over castration, not only in its results but also by affording opportunity to secure relief from other urinary complications at the time of operation. In his own hauds, however, all prostatectomy operations had been failures, but if the opinions of other surgeons could be ascertained, it would probably be found that a much larger proportion of fatal results really occurred than the figures mentioned by Dr. Cabot showed. The operation of prostatectomy has only been resorted to in cases of men who manifested considerable vigor, while on the other hand, castration has been performed in cases that were already extremely feeble, and could not stand a more serious operation, and frequently by surgeons who were not particularly expert in genito-urinary work.

DR. J. MCFADDEN GASTON, of Atlanta, spoke of a method of treatment that had recently been brought to his notice by a gentleman whose name he would not mention, the principle of which was to endeavor to reduce the size of the prostate by the employment of prostatic extracts in a somewhat similar way to the methods now employed with the thyroid extract.

DR. ROSWELL PARK mentioned two cases of castration performed by himself in which the subsidence in the volume of the prostate gland was remarkably rapid and complete. In his opinion there could not be a simpler or easier operation.

DR. ROBERT ABBE spoke of one case in which he had removed both testicles under cocain, with the result that the prostate was reduced more than one-half its size. He compared the operation of castration to that of removal of the ovaries.

DR. CABOT said the most important question was not the

ability of the operator, but the selection of the proper cases for the operation of castration. If a proper selection was made, he believed the mortality would be greatly reduced.

THE AMBULATORY TREATMENT OF FRACTURES OF THE LOWER EXTREMITIES,

by DR. LOUIS S. PILCHER, of Brooklyn. He mentioned a large number of cases of fracture in which the ambulatory treatment had been employed, and illustrated his paper with diagram of the apparatus employed. He described in detail the manner of applying the plaster bandage so as to form a sufficiently rigid and protecting case, and also explained the splints used in this method of treatment. He stated that the number of cases of fracture of the leg treated by himself up to the present time with the ambulatory dressing was twenty and the results that have followed this treatment in these cases have been very satisfactory.

This paper was discussed by DR. JOHN E. OWENS, of Chicago, who stated that cases of fracture of the lower extremity treated by this remedy might be divided into two classes, first, those that walk with the aid of crutches, but bear little or no weight upon the affected limb, and second, those that walk on the affected leg with or without the aid of pain or crutch.

After describing at some length his method of applying the dressing, demonstrating the apparatus in position and referring to cases in which he has used it, he concluded:

1. That the main object in the treatment is to enable the patient in a few days to get up and walk about on the fractured leg.
2. That union is accelerated in many cases; comfort, appetite, digestion and sleep secured; swelling, muscular atrophy, pneumonia and delirium tremens prevented and flexion and extension maintained.
3. That in the application of the dressing the foot is maintained at a right angle to the leg, and extension maintained until the deformity is corrected and the legs are of even length.
4. That the material usually employed is plaster-of-Paris in which wooden or metal strips may be included, there being a very thick plaster sole, separated from the foot by a layer of cotton about five centimeters thick, the plaster being carefully molded with the hand, so as to fit snugly against the upper end of the tibia and about the dorsum and ankle.
5. It is generally thought best not to apply the dressing until the second or third day after the accident.
6. The patient must remain under observation in order that any displacement, undue constriction or other defect may be noted.
7. In fractures of the thigh a combination of plaster-of-Paris and glue is recommended by some, while others have used special splints.
8. The plaster may be made to include the pelvis.
9. The dressing may be applied to the leg, and then allowed to harden after which the patient's hips are raised from the bed, extension being made to correct displacement and the remainder of the dressing applied.
10. An important feature of the dressing is its strong reinforcement and close application at the upper and back part of the thigh, thus securing a firm bearing against the ischium and perineum.
11. That the sooner the immobilization is effected the less will be the swelling.
12. That the method can be applied with great satisfaction, and that an exact fit must be secured.

DR. A. T. CABOT, of Boston, said that in two cases the use of Dr. Pilcher's apparatus had been a benefit in his hands.

DR. NICHOLAS SENN, DR. DE FOREST WILLARD, DR. CHRISTIAN FENGER, DR. J. EWING MEARS, DR. CHAS. B. NANCERDE and DR. GEO. W. GAY did not agree with the methods of treatment suggested by Drs. Pilcher and Owens.

DR. H. H. MIDD thought the apparatus might work very well in certain cases.

DR. MOORE stated that he had had good results from the employment of this method of treatment in two cases.

AFTERNOON SESSION.

THE TREATMENT OF TRAUMATIC LESIONS OF THE KIDNEY.

By DR. W. W. KEEN, of Philadelphia. After reading a tabulated list of 163 published cases of renal traumatism since 1878, the author stated that traumatic lesions have, as a rule, two advantages over the lesions of disease: 1, being apt to be unilateral, the other kidney is not injured, and 2, the injured kidney is apt to be healthy or fairly so. Gunshot wounds, on the contrary, have two disadvantages; 1, that the treatment of the kidney alone in many cases can not be solely considered; and 2, if the renal substance is only moderately injured, no one would be willing to do primary nephrectomy.

As to the treatment of gunshot wounds, they may be divided into: 1, those involving only the renal substance; 2, those involving the pelvis; 3, those involving the vessels, and 4, those involving the ureter. The incision in most cases, should be abdominal, either median or at the outer border of the rectus, and if the vessels are badly torn so that there has not only been a great deal of hemorrhage but the integrity of the organ is threatened, nephrectomy should be performed.

In treating the extravasated blood in case the kidney is not removed, if the bleeding is into the peritoneal cavity the blood must be removed by abdominal section, but if it accumulates in the peri-nephritic tissues alone it may be left undisturbed.

In treating the kidney, if the wound is sufficiently large for it to prolapse, it should be sutured and replaced if its condition is suitable, and the same procedure may be carried out if the pelvis of the kidney is opened. A partial nephrectomy would be advisable if a portion of the kidney is so far severed that its future integrity is threatened, and the fragment removed.

As the dangers of rupture of the kidney are primary and secondary, the treatment may be conveniently so divided. Usually it must be decided if a nephrectomy shall be done within the first few days or even hours, but it may occasionally be postponed and become a secondary operation, while the lumbar route will be best.

Of 116 cases of rupture of the kidney reported, 66 recovered. Secondary nephrectomy is nearly twice as fatal as primary.

ON SUSCEPTIBILITY AND IMMUNITY, WITH SPECIAL REFERENCE TO SURGICAL CASES.

By DR. ROSWELL PARK, of Buffalo. The author divided this subject into three classes *a*, local and general; *b*, congenital or acquired, and *c*, absolute and relative. Man seems to be immune from numerous infections, which are common to many of the domestic animals, for instance, hog cholera, symptomatic anthrax and chicken cholera, while he is in common with them susceptible to the infection of anthrax, glanders, tuberculosis and actinomycosis. Then, too, men differ among themselves in susceptibility to the same disease, and of course we explain this by saying that at the time of exposure their bodies were not receptive or more resistant.

Immunity may also be 1, local or constitutional; and 2, congenital or acquired, and acquired immunity may be natural or artificial. Immunity is, in some sense, a racial characteristic, as, for example, in the case of the Japanese, who, it is said, never have scarlet fever, but are more susceptible to beriberi than are Europeans, while the Negroes escape yellow fever and are less liable to malaria and dysentery than are Europeans.

The conclusions of surgical importance which may be legitimately reached from the study of the conditions dealt with in this paper are essentially these: That the surgeon in emergency cases has to do the best he can, not merely with the means at hand, but with the issues at hand, and here so long as he can control what may happen outside of the body, he has done his full moral and legal duty. On the other hand, in any case where patients deliberately come under observation, and where time may be afforded, it is the surgeon's bounden duty, bearing in mind a summary of the conditions which notoriously conspire upon the one hand, to lower vulnerability, upon the other hand to afford protection, to so alter the habits, the diet, the surroundings and the preparation of his patient as to restore his tissues and vital fluids, so far as possible, to their normal condition, before he interferes with their functions by an operation.

I have furthermore for years contended that since the inauguration of the so-called antiseptic era, and in our enthusiasm for combatting infection from without, we have lost sight of a most important truth, which we can not afford to disregard, viz., that in our enthusiasm for combatting infection from without, we have almost neglected the measures, first, for the recognition, and second, the successful prevention of infection from within.

THE EFFECT OF ANESTHESIA UPON THE TEMPERATURE.

By DR. DUDLEY P. ALLEN, of Cleveland. He dwelt very fully on the results obtained from a large number of experiments, principally upon dogs, and gave the details of each observation. Drs. Gay, Park, Harte, Fenger, Willard, Abbe, McGraw and Nancrede heartily endorsed Dr. Allen's methods and views.

DR. PARK, representing the Committee on the Nomenclature of Tumors, presented a printed report showing the method suggested by the committee of classifying tumors.

DR. J. McFADDEN GASTON, of Atlanta, demonstrated upon the cadaver an improved method of exploring the thoracic cavity.

DR. S. H. WEEKS presented his report as a delegate to the British Medical Association in 1895.

DR. CHRISTIAN FENGER read a paper on "Retention from Bending and Valve Formation (oblique insertion) in the Biliary Tract." He demonstrated, by morbid specimens and diagrams, his method of treating this affection.

A paper entitled "An Unusually large Periosteal Sarcoma of the Thigh Successfully Treated by Extirpation," was read by Dr. Joseph Ransohoff, of Cincinnati. The paper was discussed by Drs. Dandridge and Gaston, who mentioned cases somewhat similar to that of Dr. Ransohoff.

DR. J. COLLINS WARREN, of Boston, was elected President for the ensuing year, and it was decided to meet in Washington in 1897.

Chicago Pathological Society.

Regular Meeting, April 13, 1896.

DR. JAMES B. HERRICK, Vice-President, in the chair.

DR. ARTHUR R. EDWARDS read a paper entitled "Clinical Memoranda." (To appear in next issue.)

DR. WILLIAM HESSERT read a paper entitled "Cerebral Syphilis, with Report of Cases." (See page 1108.)

DR. LUDVIG HEKTOEN read papers on: 1, "Gumma of the Hypophysis;" 2, "Primary Carcinoma of the Ureter." (See page 1115.)

PRESENTATION OF SPECIMENS.

DR. LUDVIG HEKTOEN presented:

1. *Spindle-celled Sarcoma of the Liver*, in the Form of multiple Nodes and Nodules secondary to a Sarcoma of the Eyelid removed four Years before Death.

The liver was brought to the pathological laboratory of Rush Medical College by Dr. Koon, of Casmonia, Mich. It had been removed from the body of a man 60 years of age. Four years before death Dr. Koon had removed a small tumor of the eyelid which was diagnosed as an epithelioma. The liver weighed eighteen pounds and was the seat of innumerable large and small tumors of a whitish or grayish color. There were tumors found in the kidneys, pancreas and retroperitoneal region. Microscopically the structure was that of a medium-sized spindle-celled sarcoma.

This specimen illustrates one of the forms of secondary sarcoma of the liver, namely, the form which occurs in the shape of multiple nodes and nodules scattered indiscriminately through the substance of the organs, plainly due to embolism of tumor cells and masses.

2. *Diffuse, infiltrating Melano-sarcoma of the Liver*, secondary to Melano-sarcoma of the Eye; Ascites due to Occlusion of the Capillaries of the Liver by Tumor Cells and consecutive Thrombosis of the intrahepatic Branches of the Portal Vein.

Man, age 50, manufacturer, of dissolute habits, came under the care of Professor Holmes at the Presbyterian Hospital, Sept. 17, 1895, on account of loss of vision in the right eye which dated back about three years. Professor Holmes diagnosed the condition of the right eye, which was protruding and nodular, to be due to a melano-sarcoma of the choroid. Physical examination was otherwise practically negative. On November 15 some ascites had developed, and on the 25th of this month the ascites had become pronounced; there was jaundice and the urine contained bile pigments. The patient was passed into the care of Dr. J. A. Robison, and I have to thank both Professor Holmes and Dr. Robison for their permission to make this very brief extract from the clinical history of the case. The patient died Dec. 7, 1895, apparently from exhaustion. The postmortem examination was made one hour after death. The anatomic diagnosis reads: Melano-sarcoma of the right eye and the orbit; atrophy of the right optic nerve; metastatic tumors in the lungs, pleurae and left kidney; diffusely infiltrating metastatic melano-sarcoma of the liver; chronic congestion of the spleen; thrombosis of the intrahepatic branches of the portal vein; ascites; general bile pigmentation; chronic nephritis; chronic (left) orchitis; general arterio-sclerosis. The body is much emaciated; the skin and visible mucous membranes yellow; the right eye protruding, the eyeball nodular; the orbit is filled with a hard mass, the cornea turbid. The abdominal cavity contains a large quantity of yellowish fluid, the peritoneal layers are smooth. The pleural and pericardial cavities are empty. The heart weighs 450 grams; endocardium normal.

The lungs are edematous and contain a few small solid nodules that are grayish and in places almost black on the cut surface. Similar smaller masses are found here and there in the pleurae. The larynx, trachea and peri-bronchial glands are normal. The spleen is firm, very dark red in color, contains much blood and weighs 450 grams. The kidneys weigh 350

grams, the surface is irregular, the cortex thin, the consistence firm. In the left kidney is a small, subcapsular tumor nodule. The left testicle is firm, fibrous. The liver is very much increased in size, the left lobe being almost as large as the right; it weighs 4100 grams. The external surface is rather finely nodular, mottled bluish and gray in color; many small pin-head sized and a little larger gray tumor masses are seen on the surface. In consistence the liver is very dense and firm, like sole-leather or hard rubber. The cut surface is also irregularly nodular or granular, the predominating or ground color being bluish black with small gray districts here and there, so that the general appearance of the surface is best described as granite-like or variegated, like marble. The large vessels in Glisson's capsule and the branches of the portal vein are filled with rather softly coagulated blood. The gastro-intestinal tract is normal, but the mucous membrane is slaty in color. The pancreas is normal. The aorta and the splenic artery show a rough and irregular intima. The skull and the brain are normal, the vessels at the base being sclerotic. The interior of the right eye is partly filled with a firm tumor that seems to spring from the choroid, is quite black on the cut surface, and largely replaces the vitreous humor; at the entrance of the optic nerve the tumor extends for a short distance backward in the substance of the nerve and at the corneo-scleral junction of the internal aspect of the globe the tumor tissue perforates all the coats of the eye and spreads out into a walnut-sized retro-bulbar tumor mass which is grayish white in color with only here and there blackish or brownish dots and areas. The right optic nerve is smaller than its fellow and gray in color. Blood serum tubes inoculated from the heart's blood and the ascitic fluid remained sterile. The microscopic examination of the tumor of the eye and the nodules in the lungs and the left kidney shows the same stricture, namely, that of a small spindle-celled sarcoma, which in the eye, is melanotic, the cells here containing very much, dark brown, granular pigment, which also occurs free, between the cells. In the other places the majority of the tumor cells are not pigmented. The liver shows but extraordinary little true liver structure; it consists almost entirely of tumor tissue which is very much pigmented. Wherever the hepatic structure still remains the capillaries are found filled with small spindle-shaped, pigmented cells and in the large vessels, veins as well as arteries, are hyaline thrombi, in which are imbedded isolated melanotic cells. In some districts the tumor tissue is not uniformly pigmented. The connective tissue of the liver is not much increased and distinct bands of fibrous tissue are not present. From this examination it can be concluded that an almost continuous, capillary embolism, or immigration, of melanotic sarcoma cells took place from the primary choroidal melano-sarcoma, that these cells passed almost unhindered through the pulmonary capillary network—only a few small tumor nodules are present in the lungs—and became lodged in the capillaries of the liver which the cells reached by way of the portal vein as well as by way of the hepatic artery. Only a very few cells were diverted from this course as shown by the presence of but one metastatic tumor outside of the lungs, pleurae and liver, namely in the left kidney. In the liver this continuous capillary embolism resulted in the development of a diffuse tumor growth which replaces the liver tissue proper while it largely retains the normal external conformation of the liver. Larger nodules are not found in the liver. Finally the capillaries and smaller vessels become so packed with tumor cells that the portal circulation is obstructed, ascites develops, and thrombosis of the intrahepatic branches of the portal vein is induced. The development of ascites upon this basis—obstruction of the portal capillaries by melanotic sarcoma cells—is exceedingly interesting and has not been mentioned in the current descriptions of this remarkable form of secondary sarcoma of the liver, the diffuse infiltrating variety. This form of secondary sarcoma of the liver—it practically always concerns melano-sarcoma, may also develop years after the removal of the primary tumor. Thus in an instance referred to by Birch-Hirschfeld seven years intervened between the operation and the demonstration of a diffuse pigment sarcoma of the liver.

3. *Primary Large, Round-Celled Sarcoma of the Left Lobe of the Liver*; Sinus Thrombosis and Thrombosis of the Pial Veins of the Convexity.

Paul P., harness maker; was admitted to the Cook County Hospital (Service of Dr. Leahy, Dr. Ryan in charge) Sept. 24, 1895, and died Oct. 2, 1895. Extract from the clinical history: Well nourished; delirious; pupils equal and active; paralysis of right internal rectus; mouth drawn to the right; neck muscles rigid; double optic neuritis; right arm and leg are paralysed. Lungs and heart normal, pulse slow and regular. The liver dullness reaches from fifth rib to costal arch. In the left hypochondriac region is a hard mass that reaches

beyond median line and seems continuous with splenic dullness: it moves with respirations and is covered by a tympanic area. Gonorrhea: urine normal. The delirium gradually gives way to stupor that deepens into coma. There is conjugate deviation of the eyes to the left. Shortly before death the temperature rises to 100.8-102, and the breathing becomes rapid.

Clinical diagnosis: Tumor of the pancreas: multiple cerebral tumors? Meningitis?

Anatomic diagnosis: Tumor of the left lobe of the liver, tumor nodules in the mesentery, omentum, spleen and at the tail of the pancreas; thrombosis of the dural sinuses and of the veins of the lepto-meninx of the convexity: multiple capillary hemorrhages into the cortex about the left calcarine fissure: fibrinous pneumonia: thrombosis of inferior vena cava.

Extract from the protocol: General nourishment good, peritoneal cavity empty. Pleural cavities obliterated by firm adhesions. Pericardium smooth and shining.

Heart weighs 310 grams, endocardium normal. The lower lobe of the right lung consolidated, gray and granulated on the cut surface. Thyroid gland normal. Bronchial glands anthracotic. The omentum is adherent to the liver and contains two small, firm, reddish-gray tumor nodules. The left lobe of the liver is occupied by a large nodular mass about 10 cm. in diameter, which seems to have replaced all the liver substance proper. The right lobe is normal so that the liver may be said to consist of a normal right lobe which merges into an irregular tumor of almost the size of a child's head. Externally the tumor is nodular, firm; on the cut surface it is grayish-red in color: in the center are calcareous masses, and from the center appear to run radiating cicatricial bands that gradually disappear toward the periphery of the growth. But little liver tissue can be recognized around the tumor which merges gradually with the right lobe. The pancreas is normal. Situated above the tail of the pancreas and distinct from the latter is a firm, reddish-gray mass about as large as a hen's egg. The spleen is normal, but there is a small tumor mass underneath the capsule. The kidneys and adrenals normal; bladder, testicles and seminal vesicles also appear normal; the mucous membrane of the urethra is covered with a small amount of pus. The gastro-intestinal tract is normal. The vena cava contains a grayish, granular thrombotic mass adherent to the intima just below the entrance of the hepatic vein. The skull is normal; all the dural sinuses are filled with adherent, reddish-gray, rather soft blood clots, which extend into the veins of the lepto-meninx of the convexity, which stand out prominently like whip cords and contain red thrombi. The ventricles are empty and not dilated. There is some increase in the cerebro-spinal fluid, but no inflammatory exudate. The brain substance seems quite normal but the gray matter bordering upon the left calcarine fissure contains innumerable minute hemorrhagic extravasations, the puncta vasculosa are everywhere large and apparently very numerous, and the color of the white matter is quite pinkish. The jugular veins are empty, the intima smooth, and there is no thrombosis. The cavities and sinuses of the cranium are normal.

The microscopic examination of the tumor of the liver and the smaller nodules show that all present the same structure, namely, large, roundish cells with deeply staining, rather small nuclei. The cells are imbedded in a fibrillated vascular stroma which separates the individual cells one from the other at the same time as it is collected into broader bands that divide the tumor into smaller and larger cell groups. The large round cells seem to bear a very close relation to the vessels, which are very numerous and present thick walls and at times a proliferating intima. Any direct relation between the endothelium and the tumor cells could not be demonstrated. From the adventitia of the vessels pass the strands of fibrillated connective tissue forming the stroma. In the liver, hepatic cells or bile ducts can not be found in the central part of the tumor. Nearer the periphery the tumor cells compress the liver cells and seem to cause atrophy of the latter.

From these appearances the diagnosis of a primary large, round-celled sarcoma of the liver with metastasis at the tail of the pancreas, in the mesentery, omentum and the spleen, seems warranted because of the great size and evident age of the liver tumor, the comparatively insignificant size of the other tumors, and the absence of any larger tumor in any part of the body to which all the above growths might be secondary. Evidently the sarcoma originated in the perivascular connective tissue of Glisson's capsule in the liver.

The occurrence of such extensive thrombosis of the cerebral sinuses and lepto-meningeal veins, to which the marked cerebral symptoms are referable, is very interesting from a diagnostic as well as a pathogenetic standpoint, but the further consideration of this question must be left to some future time. While

the liver is the most frequent seat of secondary sarcoma next to the lungs, primary sarcoma of this organ is very rare. Hence the demonstration of this specimen. Arnold,¹ in 1890, reported two cases because he had thought up to that time that primary sarcoma of the liver did not occur. He was able to collect twenty-six cases from the literature which were reported as primary. Histologically these cases represent the principal varieties of sarcoma; the pigmented form, however, is almost always secondary. Thus Hanot et Gilbert² exclude all the instances reported as primary pigment sarcoma but one.

DISCUSSION.

DR. EDWARDS—The third case of sarcoma of the liver that Dr. Hektoen has presented, might have some clinical interest in that the tumor in that case was diagnosed as a carcinoma in the region of the left lobe, or the region of the fundus of the stomach: the exact source of origin of the tumor could not be determined because of the obvious broad attachment of the tumor. The main point of interest in the case is that the patient developed many months before death, very marked cerebral symptoms. He had symptoms some six or eight months when he was in the hospital for the first time, and at that time particularly his symptoms were vague; they were by no means focal. He received anti-syphilitic treatment, and there was, after a number of months, a distinct remission in the cerebral symptoms. He came back to the hospital; had been in the hospital for some time with this tumor and he began gradually to evince more pronounced cerebral changes. He had at first a distinct choked disc, the veins stood out very prominently, and besides the venous changes, secondary change in the disc itself. The optic inflammation and passive congestion, together with the mental symptoms, made it highly probable, arguing from the facts, that he had neoplasm of the abdomen, with a metastatic deposit in the brain. The cerebral symptoms were mainly diffuse, though it was said one convulsion was localized in one side of the body. He had a delirium, he had a strabismus, one internal rectus being affected. Our surprise at the postmortem was great, that, instead of having a neoplasm, which we might reasonably have expected from the abdominal neoplasm, there was a thrombosis in some, if not all, the cerebral sinuses.

DR. HOLBROOK presented a specimen of *Myosarcoma of Cerebellum*.

This specimen is of interest, not alone from its rather unusual pathologic condition, but from the long observed clinical history which it produced. The patient had been examined and treated and watched by a large number of physicians and specialists, and although the diagnosis of brain tumor had been indefinitely settled upon, there was great variance of opinion as to the variety, the location and complication. The specimen is taken from a case which was admitted to the Presbyterian hospital in January, 1895, and was put under the service of Dr. Robison, who has kindly consented to let me give the clinical details. The clinical history is briefly as follows: A year before admission severe gastric disturbances appeared which were called bilious attacks, with persistent vomiting and constipation of bowels. Cerebral symptoms developed a short time later: especially diffused headache, the headache localizing at times in the occipital region and in the posterior cervical region. Shortly after these symptoms developed, the patient noticed interference and impairment of vision. The tumor, you will notice, is located on the left side. The first impairment of vision was naturally in the right eye. This continued until the eye was completely blind, the left eye being involved shortly after and upon admission to the hospital after the space of a year, the patient was able to distinguish light from darkness and marked outlines with the left eye. Upon admission the examination of the eye showed the pupillary reflex to be prompt and normal and the pupils to be dilated equally upon both sides. Other symptoms: General weakness on the right side of the patient's body although he was a right-handed man; there was no paralysis or anesthesia noticed at that time, and the reflexes were as were to be expected, all normal excepting for the right knee jerk, which was exaggerated.

About four or five weeks before his death the patient developed convulsions; these would occur at intervals of days at first, and finally occurred two or three times daily. The first convulsion consisted of muscular spasms on the left side of the body, but after this the convulsions were started on the left side, but also involved the right side. During this time the patient's eyeballs were noticed to be anesthetic, but these were the only signs of anesthesia found, even the cornea could be touched with no action on the part of the patient. The night

¹ Ziegler's Beitrage, viii, 1890.

² Etudes sur les maladies du foie, Paris, 1888.

before the patient died he was in constant convulsions; in the morning he was comatose and died very suddenly. The autopsy was held about twenty-four hours after death by Dr. Hektoen. The patient was well nourished; no metastatic tumor was found in any portion of the body; there was a congested condition of the organs of the thorax and abdomen. On cutting open the skull cap, the calvaria was found to be very thin, especially so in some rough and reddened spaces; the dura was seen to be flattened over the area, the convolutions under the dura were seen to be flat, showing a diffused and general pressure which seemed to be equable; the fissures were obliterated. On removing the skull, the lower part of the base of the skull was found normal, and the brain was cut open; the ventricles were found to contain a fluid which passed freely from one ventricle to the other, and distended the ventricles very markedly. The growth to which I would particularly call your attention was on the left cerebellar lobe. I have located it upon diagrams. The growth as here represented is 6 centimeters long, 4 wide and 3 deep. It impinges upon the medulla so as to compress the left half, and has displaced the right half, as can be seen on the specimen. The pia mater over the growth was free; it is attached firmly to the cerebellar substance, from which it evidently arises. It impinges upon the last six nerves. The substance of the cerebellum around the tumor is considerably softened; the tumor was of a medium consistency. On making microscopic examination, the tumor was found to be a myxosarcoma; the blood vessels are numerous; there are some hemorrhagic areas which you will notice in the section, which, however, are not numerous nor characteristic. The history of twenty-seven months is rather long for a sarcoma with the symptoms as given; perhaps the myxomatous degeneration had much to do with modifying the malignancy. I think the symptoms which are given and one which I omitted, that of the complete loss of hearing in the left ear, are easily made compatible with the anatomic findings.

Illinois State Medical Society.

Abstract of the Proceedings of the Forty-Sixth Annual Meeting, held at Ottawa, May 19, 20 and 21, 1896.

FIRST DAY—MORNING SESSION.

The society met in the First Baptist Church, and was called to order by the President, DR. D. W. GRAHAM, of Chicago.

Prayer was offered by the Rev. Dr. Burhoe, of the First Baptist Church, after which the president made a verbal report of the work of the Executive Committee, as *ex-officio* Chairman. Then followed the reports of the Committee of Arrangements, Committee on Registration, etc.

Dr. C. W. HALL, Kewanee, offered the following resolution, which was unanimously adopted:

WHEREAS, Resolutions concerning vivisection were passed by the AMERICAN MEDICAL ASSOCIATION at Atlanta; therefore be it

Resolved, That the resolutions mentioned and published in the JOURNAL of the AMERICAN MEDICAL ASSOCIATION express the sentiments of the Illinois State Medical Society, and that our Secretary be requested to send copies of these resolutions to the members of Congress from our State.

FIRST DAY—AFTERNOON SESSION.

Section One. Practice of Medicine, Medical Specialties and Therapeutics.

Chairman, DR. J. T. McANALLY of Carbondale: Secretary, DR. C. W. HALL, of Kewanee.

The first paper read in this section was by Dr. E. FLETCHER INGALS, of Chicago, entitled

ORRHOTHERAPY IN DIPHTHERIA.

The author stated at the outset that as a result of the work of Pasteur and the numerous investigations which have followed in the same line, it is now generally believed by bacteriologists that many diseases, especially those which seldom affect individuals more than once, are self-limited by the formation within the blood of a product capable of destroying the toxic material that excites the disease, hence called antitoxin. In such diseases, if life be prolonged until a sufficient quantity of the antitoxin has been developed, the toxic agent is destroyed and recovery follows if no serious complications have arisen. In diseases that can be communicated from man to animals and vice versa, such, for example, as rabies, anthrax and diphtheria, advantage has been taken of this fact by inoculating animals with the attenuated toxic principle in small but steadily increasing quantities until an antitoxin is developed in the

blood in sufficient quantity to render the animal immune to the further pernicious effects of the contagion.

The author then referred to the law enunciated by Behring that blood and blood serum which had in this manner been rendered immune might be transferred into another individual with the effect of rendering the latter also immune, no matter how susceptible he might be to the disease. The investigations of Kitasato, Aronson, Roux and Behring were considered at some length.

Coming to the question of diphtheria, the author stated that the diphtheritic poison had been introduced into animals, preferably into the horse, until immunity to its further effects had been obtained. The animal was then bled, the blood allowed to separate and the serum preserved under the name of antitoxin.

One thousand antitoxin units is considered the ordinary curative dose, but in severe cases, or those not treated until the third day, 1,500 to 2,000 units are often employed, and sometimes these are repeated until altogether from 4,000 to 6,000 units are administered in a single case. The dose considered necessary for immunizing a healthy individual is about $\frac{1}{4}$ the curative dose. The serum is administered by hypodermic injections, preferably in some part of the body where there is an abundance of loose cellular tissue, as at the lower angle of the scapula, in the gluteal region, and upon the abdominal or chest walls. Dr. Chantemesse reports that he has had quite as good results when administering the antitoxin per rectum as by hypodermic injections.

Attached to the paper was a table showing a large percentage of complications after the antitoxin treatment. By far the most frequent complication was a rash, usually urticarial, sometimes erythematous, or having the appearance of scarlatina. A rash was observed in 45.9 per cent. of all cases. This was accompanied by fever in many cases amounting to 29.6 per cent. of the patients presenting a rash. In some instances the rash persisted for many days, but usually it had run its course by the end of the third or fourth day. There were a few instances of effusion into the joints and abscesses were found at the site of injection in 2.3 per cent. of the cases.

The consensus of opinion of observers as to the symptoms manifested after curative doses of the antitoxin is that the temperature may be either reduced or rendered higher, though it appears that in the majority of cases it is rendered somewhat lower in the next twelve or twenty-four hours. The pulse is strengthened and the general condition appears to be improved in the same time. Extension of the diphtheritic membrane to other parts is checked and the membrane commonly begins to loosen within twenty-four hours. The remedy, however, does not prevent suppuration of the cervical glands, does not prevent paralysis, and does not favorably modify paralysis when it has once appeared.

The reports of clinical investigations taken as a whole are greatly in favor of the antitoxin treatment. There is still some skepticism as to the efficacy of the remedy based upon the fact that no crucial experiments have been reported. It is well known that the mortality in diphtheria varies from 10 to 75 per cent. in various epidemics or in different portions of the same epidemic: therefore, accurate information can not possibly be obtained by comparing the death rate of any year with that of any preceding year, or even by comparing the death rate of one month with that of preceding or succeeding months. Until in the large hospitals alternate cases are treated by antitoxin alone and by other methods, we will have no certain information upon the subject. The report from the municipal hospital of Philadelphia approaches nearer a crucial test than any other the speaker had been able to find. It unfortunately shows a higher death rate with antitoxin than without it, even though the antitoxin was given mostly to those cases that were considered to be especially favorable for its action, and in extreme conditions it was withheld.

Dr. Ingals closed his paper with the following language: "Until more definite information is obtained conservative physicians may well be excused for declining to experiment with this remedy upon their patients; however, the wide belief that it does much good and the comparatively certain knowledge that it does but little harm suggests that our duty to our patients demands that when diphtheria exists we should administer the antitoxin, if it is desired, but that at the same time we should use such other remedies as have been proven of most value in combatting this disease: but we should hesitate to recommend it as a prophylactic measure. We believe that the experimentation in the treatment of diphtheria by serum is in the right direction, and we hope that the enthusiastic friends of orrhoterapy may be largely vindicated; yet we can not search far into the history of medicine to find that very many of the remedies now employed have in the begin-

ning been lauded excessively, and that not a few of those that were formerly supposed to be extremely efficacious have been found to be practically worthless."

TREATMENT OF TUBERCULOSIS

was the title of a paper read by DR. N. S. DAVIS, JR., Chicago, in which he said that the establishment of serum antitoxin as a successful remedy for diphtheria by the elaborate experiments of Behring, Kitasato and others, suggested the employment of serum prepared by analogous methods for tuberculosis. Tuberculin and the products derived from it had fallen into almost complete disuse. A few still employed them. Serum was employed as a cure for tuberculosis in 1890. Recently serum from horses, made immune to tuberculosis by inoculations successively with viruses of gradually increasing virulence, has been prepared and tried independently in Italy, France, Austria, and in this country. Good results are reported with much uniformity from the employment of this serum in cases that are not complicated by serious infection with other microbes than the tubercle bacillus. The ordinary dose is 2.5 c. c. administered hypodermatically daily, or every second day. Much larger doses have been employed, but not with proportionately better results. The heart and arteries are not affected by these injections. A leucocytosis follows them. Increase in the number of red blood corpuscles and hemoglobin occurs as general improvement takes place. As a rule the urine is not materially modified. In a few instances albuminuria and peptonuria have been provoked, but no serious lesion of the kidneys. Appetite is almost uniformly improved after the first few injections and increase in bodily weight rapidly follows.

The author's experience with this treatment is limited to a single case now under observation, and from it he says he can not yet draw conclusions. The treatment seems to be harmless, and in suitably selected cases, to promise improvement. Much more time must elapse before we can with confidence pronounce such improvement a permanent cure.

Creasote and its derivative, guaiacol, and their compounds, continue to be generally used. In the early stages of pulmonary consumption these drugs often prompt improvement both general and in the diseased lung. Many observers have ascribed these good results to the effect of the preparations upon digestion and nutrition.

Dr. Davis maintains that for the treatment of consumption we must still rely chiefly upon hygienic and symptomatic treatment. A life in the fresh air, in suitable climate, with rest or properly regulated exercise, a generous but varied diet, and mental as well as physical comfort, promise greater success than any of the possible specifics now being experimented with.

DR. JAMES B. HERRICK, Chicago, read a paper entitled

THERAPEUTIC USES OF THE THYROID EXTRACTS.

He reviewed at considerable length thyroid therapy, and presented the conclusions that one feels justified in drawing from a study of the work already done in this line of the employment of this remedial agent in various diseases. His deductions concerning thyroid extract are:

1. It is curative in myxedema (idiopathic, cretinism, operative).
2. Many cases of obesity are cured by it.
3. Simple hyperplastic struma, particularly in the young, is frequently cured or improved.
4. In one, two and three the remedy has to be continued for an indefinite time in order to prevent relapse.
5. It may prove of value in some cases of tetany.
6. In skin diseases it is of doubtful value to say the least.
7. The same is true of mental and nervous diseases.
8. In exophthalmic goitre it is contraindicated.
9. The results are practically the same whether fresh glands, extracts, or dried glands are employed.

This is probably true also of the thyroiodin of Baumann.

HOME CARE AND TREATMENT OF EPILEPTICS.

This paper was read by DR. A. L. WARNER, of Kankakee, after giving an outline of epilepsy, the author stated that the percentage of complete recoveries from this disease was small owing to its obscure nature and to the fact that only in a small number of cases does treatment seem to have more than a palliative action. There is also a great difficulty in getting patients to take the long and systematic medication required and to live in accordance with the rules laid down by the physician, and if treatment is not given early and a cure effected, the epileptic habit which is established, in itself becomes a grave and difficult complication. There is very little doubt but what many cases of epilepsy could be prevented by proper systematic treatment.

In referring to the preventive treatment, the author called especial attention to the fact that even slight head injuries may sooner or later become active factors in the causation of epilepsy and such injuries should be closely examined and receive proper treatment not only for the injury itself, but to prevent the possibility of a person becoming subject to epilepsy at a future time.

The treatment of epilepsy resolves itself into 1, the treatment of the convulsive seizure; 2, treatment, medical, hygienic and surgical, to prevent the recurrence of seizures, and 3, treatment of complications.

When bromids fail to give favorable results alone, their influence can often be increased by giving them in combination with other drugs. Fleschsig's treatment, consisting of giving one-quarter of a grain of extract of opium morning and afternoon, increasing at the rate of one-half grain daily until 15 grains daily is reached, then discontinuing the opium and substituting 30 grains of bromid of potassium three times daily, gradually reducing the amount to a point where it can be continued with safety for a long period of time, has been highly recommended by those who have used it, but while it seldom effects a cure, it has special advantages in cases of long duration and where the patient is of an irritable and violent disposition.

The surgical treatment of epilepsy has come more prominently into use during the past two years. Under aseptic conditions, trephining for elevation or removal of depressed bone has become common, and even excision of portions of the cortex of the brain have been made by some with the view of destroying the supposed explosive center. Operations for the removal of diseased tissues, and meningeal and brain tumors have also been followed frequently with good results.

Finally, the author stated that it was to be regretted the progressive State of Illinois had not yet provided a hospital for epileptics, where they could be cared for and treated in a systematic manner by physicians and nurses who made a specialty of this disease, and in the event of its being of an incurable nature, to have a home provided by the State in which they may have comforts and surroundings suited to their peculiar needs.

HYSTERO-EPILEPSY.

DR. HUGH T. PATRICK, Chicago, first defined hystero-epilepsy as not epilepsy at all in any sense of the word, but hysteria pure and simple. He then proceeded to describe a typical paroxysm of hystero-epilepsy, an attack which he said is rarely seen, but serves well as a basis for the description of the incomplete or aberrant forms which are of frequent occurrence. The different periods and sub-stages were accurately described and illustrated by a number of well executed drawings. He showed that in an attack of hystero-epilepsy there is nothing after the first or epileptoid period that in the least resembles epilepsy. A patient who struggles, has to be held, who makes exclamations, tears the bedding, or tries to bite himself or others, is not an epileptic. A patient who shows marked opisthotonus, rolls over and over, or performs acrobatic feats, is not an epileptic. A patient who assumes striking postures or shows exalted psychic action during the attack, is not an epileptic. An attack that lasts fifteen minutes or more is not epilepsy.

DR. PATRICK then gave in detail the points in the differential diagnosis between an hysteric attack closely simulating epilepsy and true epileptic convulsions.

In conclusion, he insisted that hysteric convulsions are not confined to Paris and the Salpêtrière, but are of rather frequent occurrence in this country in the small towns as in the large cities. He has seen in the last few months a number of cases of hysteric convulsions which had been thought to be epilepsy, and had been treated as such for various lengths of time.

DR. J. B. MAXWELL, of Mt. Carmel, read a paper entitled,

STATUS OF EPILEPTIC LEGISLATION.

Among the special reasons for the establishment of a colony of epileptics he gave:

1. For the welfare of the epileptics whose numbers justify the outlay.
2. For the welfare of the insane, who should not be compelled to associate with them in the hospitals.
3. To diminish, so far as possible, the overcrowding of the hospitals for the insane.
4. To remove the epileptics from the almshouses, where it is a hardship for many of them to be, as under favorable circumstances they would be able to work and might be restored to health. The benefit that must accrue to epileptics in particular, and society in general, would be great, and scores, if not hundreds, who now refuse to enter the dark portals of the hospitals for the insane, or the forbidding gates of the institu-

tion for the feeble-minded, would be glad to enter the home or colony for epileptics. The speaker is convinced that too much time has already been lost and he strenuously recommended immediate legislation in behalf of epileptics.

FIRST DAY—EVENING SESSION.

The First Vice-President, DR. J. M. G. CARTER, Waukegan, took the chair, and after a musical selection rendered by the Eolian Quartet of Ottawa, the President, DR. D. W. GRAHAM, of Chicago, delivered the annual address. He selected for his subject,

THE MUTUAL RELATIONS OF THE MEDICAL PROFESSION AND THE PUBLIC.

(This address will appear in full in a subsequent issue of the JOURNAL.)

DR. HAROLD N. MOYER, of Chicago, then followed with an address entitled,

NEEDED MEDICAL LEGISLATION IN ILLINOIS.

He said that medical legislation in this State had been fairly fruitful in the past. An examination of what had been accomplished, while pregnant with promise for the future, is still far short of what should be. To this State belonged the proud distinction of having first placed upon its statute books a law regulating the practice of medicine. This was followed by our best piece of law-making, the anatomical bill, which, as amended, is as nearly perfect as could be wished. By it anatomical study has been placed within the reach of students of medicine to a degree and with a perfection that leaves nothing to be desired.

The law regulating the admission of insane patients to our hospitals, which has been in operation for the past two years, was rendered much less effective than it otherwise would have been, by a stupid amendment which has made its construction very difficult. As it was prepared by a committee of this Society, and submitted to the legislature, it was a symmetrical bill, providing not only for a trial by jury, but also for the appointment of a commission and for self-commitment. These were all separately described in the bill and provision made for carrying them out.

Dr. Moyer then passed on to the consideration of expert testimony, saying it had been taken up and considered at the last session of the legislature, and a bill regulating this important branch of judicial procedure narrowly missed enactment. In his judgment this bill ought again to be brought forward and an effort made to pass it. By many it was thought to be too conservative, but the speaker feels convinced that in this as in many other cases, to go slowly is to go surely. As at present proposed, the law is restricted to expert testimony in criminal cases. It alters the manner in which experts are summoned, without in any way changing the rules of practice and evidence, after they are in court. That some reform is needed in this regard is shown by the fact that not a week passes without some article appearing in the medical press upon this subject, and it forms a perennial topic in all medical society meetings.

Closely related to this subject is the question of compensation of expert witnesses, a matter intimately related to the personal rights of physicians. Dr. Moyer then referred to the case of Dr. J. N. Dixon, of Springfield. Dr. Dixon is now prosecuting on appeal in our Supreme Court a case involving the rights of physicians in this respect. The trial court went farther in summoning Dr. Dixon and compelling him to testify than the speaker had ever known a court to go in the State of Illinois. Another matter which required legislation was that which related to public inquests and the coroner system.

The author paid an eloquent tribute to the late Dr. John H. Rauch and his *confrères* who had so well laid the foundation of higher professional education.

Finally, the time for an Examining Board had arrived. The various schools could then meet on the common ground of anatomy, chemistry, pathology, bacteriology, and above all a thorough test of a candidate's knowledge of the English language, and general scientific attainments.

SECOND DAY—MORNING SESSION.

DR. C. B. HORRELL, of Colchester, read a paper on

DIAGNOSIS OF TYPHOID FEVER.

Two potent factors essential to success in a physician are a good diagnostician and a good collector. A physician should never be too busy to thoroughly examine each and every case that presents itself to him, and it will redound more to his reputation to carefully investigate and properly diagnose half a dozen cases a day, than to superficially and hastily examine and indiscriminately in a routine way prescribe for half a hundred.

The speaker had not always found the diagnosis of typhoid

fever an easy task, not even in simple uncomplicated cases. He insisted that without careful and exhaustive physical examination of the patient and investigation of his surroundings, the physician was likely to be placed under the embarrassment of a mistaken diagnosis. The author said that if his paper would be the means of stimulating a more systematic and perfected study of physical diagnosis in general, its object would have been attained.

THE TREATMENT OF TYPHOID FEVER.

DR. JAMES P. LYTLE, of Princeton, read a paper on the above subject. After dwelling at considerable length upon the various treatments of typhoid fever the author said that whatever may be our present or future treatment of this disease, good judgment and common sense in its management would ever remain the chief elements of success. The late Dujardin-Beaumez recognized this. At the end of a busy life full of years and good works, he left this legacy as the result of his experience, "That the best treatment for typhoid fever is a good physician."

DR. JOHN A. PRINCE, of Springfield, read a paper entitled,

PELVIC ABSCESS.

The author dwelt upon the surgical treatment, citing a few cases that had occurred in his own practice. He believes that in nearly all cases the infection is from the tubes, and that whether the abscess is a true pyosalpinx, an ovarian abscess, or independent of the uterine adnexa, the tubes constitute the channel of infection.

The surgical treatment resolves itself into the various methods of evacuating the pus. The various methods might be classified as follows: 1, laparotomy with extirpation of abscess mass; 2, laparotomy with cleansing and drainage of abscess cavity; 3, drainage by vaginal hysterectomy; 4, drainage by vaginal incision; 5, aspiration.

Laparotomy with complete extirpation of the pathologic tissues involved in the abscess is, he thinks, the ideal method, and where practicable should be employed.

Vaginal hysterectomy for the cure of pus cases was of very recent origin, and as the speaker's experience was limited to one case, he was not prepared to speak with authority.

As regards aspiration it is merely a palliative measure, and should not be considered among the methods of cure. He had been best satisfied with the results obtained by complete enucleation, but in some cases after opening the abdomen, it had been found impossible to remove the mass and gauze packing had been employed, and while the ultimate results had been good, convalescence had been slow and protracted.

THE NECESSITY OF CLOSE INSPECTION IN HEAD INJURIES.

The author, DR. R. E. LEWIS, Macomb, emphasized the importance of investigating every case which comes under observation. Sufficient time had now elapsed since the inauguration of operative procedures upon the cranium and brain for the cure of various mental and physical defects, to judge somewhat correctly of their merits, and in looking over the reports of cases with subsequent histories in the hands of the most competent operators, the speaker was astonished to find so small a percentage of actual cures resulting from what at first seemed brilliant and promising results. After relating an interesting case of depressed fracture of the skull, which the author had treated successfully, he drew the following conclusions:

1. All scalp wounds will bear close inspection.
2. The trouble resulting from pressure on the brain should be removed before they arise.
3. This work should be done by the general practitioner in the rural districts, as well as by skilled surgeons in the city.

DR. JOSEPH B. DELEE, of Chicago, read a paper entitled,

CRANIOTOMY ON THE DEAD CHILD.

He gave the following indications for craniotomy:

1. All cases where the child is dead, an indication for the termination of labor arises. This operation should be done instead of the forceps, when the maternal soft parts are unprepared for rapid delivery. Such cases are eclampsia, placenta previa, premature detachment of the normally implanted placenta, prolapse of the cord with danger to the mother from any cause. In short, do not apply the forceps on the dead child. The only exception the speaker would make to this rule was the case of a multipara, with the head low down and the soft parts well prepared.

2. Cases of contracted pelvis when the conjugata vera is not smaller than 2½ inches. To do a hard version or extraction or a forceps, or a Cesarean section is not justifiable when the child is dead.

3. In neglected transverse presentation embryotomy should be done. The thought of a version should not be entertained for a moment.

DR. EMMA B. STANDLEY, of Alexis, contributed a paper on
(CLEANLINESS IN OBSTETRICS.

The first step in cleanliness in obstetrics was for the physician to be clean himself, when called upon to attend a woman in confinement. He should be clean in morals, words and expression; clean in person, providing himself with all the necessary aids to help him in his work as an obstetrician. She thought the day was passed when a physician would allow a woman after the babe was born and placenta removed, to lie undisturbed for twenty-four hours or more, without the soiled things upon her bed being removed. Her plan has always been to allow the mother to rest for a little time after delivery until the babe is attended to, then a bowl filled with warm water is brought and a disinfectant added, and the pudendum thoroughly cleansed, being careful not to expose the patient. As the bed proper is protected with rubber cloth, the soiled bed-clothes are easily removed, the vulva being protected with a soft disinfectant pad in order that no lochia may escape upon the bed while this is being accomplished. When possible, the speaker prefers to confine a woman upon a couch, or another bed near by, and then after the woman is rested and cleansed, have her lifted into a comfortable bed.

At the time of confinement the author has found a hot bath to be both cleanly and a help to such women, using a bathtub, or if that is not to be had a washing tub is used to bathe them in. This relaxes and assists nature. Another help to cleanliness in obstetrics was the rectal enema of warm water that the bowels might be thoroughly moved. This had a relaxing effect upon the sphincter ani muscle and perineum and prepared the way for the advance of the child far better than if the physician had a loaded rectum to contend with. The author next considered cleanliness of the cord, saying that she had found the subnitrate of bismuth a good dressing. The uncleanly practice of drying the diapers and putting them again upon the babe without washing was too often done. This produced soreness from the decomposing urine and should be condemned by the physician.

SECTION ONE—SECOND SESSION.

DR. GEO. G. CRAIG, of Rock Island, read a paper entitled,
HYDROTHERAPY IN THE MANAGEMENT OF HIGH TEMPERATURE
IN TYPHOID FEVER.

The author stated that notwithstanding all that had been written and said upon this subject, the practice had been confined essentially to a few hospitals in large cities. That it was not more generally adopted was due to the fact that more trouble and care are required than in treatment with medicine. In the second place the new departure was looked upon with disfavor by a large class of people, who could not bear the idea of plunging a patient with a temperature of 105 into a tub of cold water to have him "catch his death of cold."

He enumerated the methods generally used for applying hydrotherapy in the treatment of typhoid fever. Like any other remedy, judgment must be exercised in the selection of the mode and manner of administering it in each individual case, bearing in mind that statistics prove that the nearer the exact technique of Brandt is and has been followed the better the results. We must consider the prejudice and fear on the part of the patient or friends and adapt the treatment to the circumstances, but it was the duty of the physician, however, if he believes that a larger percentage of cases recovered under this treatment to use it. In all cases the physician could not let his views be known, and in hospital practice particularly, and in private practice when possible, the author believes that we should adopt it as a whole or in part.

SECTION TWO—SECOND SESSION.

DR. O. B. WILL, Peoria, read a paper entitled "Some Observations Respecting the etiology of Ectopic Pregnancy."

DR. J. B. MURPHY, Chicago, followed with a demonstration of the

SURGERY OF THE GASSERIAN GANGLION,

and reported cases. He confined himself almost exclusively to the technique of the more recent operation, after reviewing the results of previous operations for the removal of the ganglion. Internal medication and anodynes had absolutely failed to permanently relieve the intractable neuralgias of the face. Reference was made to the methods advised and advocated by Rose, Horsley, Andrews and others for the removal of the ganglion. Dr. Murphy then described in detail and illustrated a slightly modified technique of the Frank Hartley operation. He said there had been forty-seven cases collected up to date with only two deaths. One of the patients died shortly after the operation from shock. The other death was presumably due to the advanced age of the patient.

DR. JOSEPH B. BACON, Chicago, contributed an interesting paper on "Dermoid Cysts as a Cause of Fistula in Ano."

(To be continued.)

American Laryngological Association.

Annual Meeting held at Pittsburg, Pa., May 14, 15 and 16, 1896.

The session was opened by an excellent address by the President DR. W. H. DALY, Pittsburg, Pa.

THE PROPHYLAXIS OF NASAL CATARRH.

DR. CARL SEILER, Philadelphia, stated in this paper that there is but one primary cause which produces this prevalent disease and that any other cause is merely the expression of a predisposition called into action by the former. Anything which produces acute inflammation of the anterior and posterior nasal mucous membrane will lay the seed for pathologic changes in that very tissue, causing chronic infiltration and the subsequent deposit of connective tissue.

The earliest causes of nasal catarrh in childhood are primarily over-clothing, over-feeding, and consequent over-heating of the body. There seems a curious apathy on the part of parents and the family practitioner as well, in regard to this condition, in allowing one attack after another of acute coryza to develop a chronic catarrhal condition. It is therefore the duty of medical advisers to instruct parents in the method of applying those preventive measures which may be readily instituted. When an acute coryza has developed the accumulation, inspissation and putrefaction of the mucus should be at once prevented. The same care should be given to the nasal mucous membrane that is now given to the teeth, and a normal condition of that tissue would be the rule rather than the exception.

A child should therefore be taught, as soon as possible, to snuff up a warm saline solution in the nose. The solution may be snuffed up either from the hollow of the hand or from a small cup, or glass, three or four times a day. A douche or atomizer should not be substituted for this method of artificial application for nasal cleansing. The simpler method is preferable because of its readier application and because of the child's natural abhorrence to the use of any instrument. Moreover the douche and the atomizer do not accomplish their purpose any more successfully than does the simpler method and the extra pressure which is brought to bear on the mucous membrane by such appliances can readily produce more harm than good. Antiseptics may be added to the solution at the discretion of the physician in order to prevent putrefaction and inoculation with the septic material. As important, however, in the treatment of such a case is the proper feeding and clothing of the child so that the general system may not be over-heated. The skin of the neck and arms, moreover, should be so hardened by cold water applications in the form of sponging night and morning that moderate exposure will not readily give rise to acute coryza. The author believes that American children in particular are, as a rule, too much clothed, too much confined indoors, and are overfed with heat-producing food. Too often when these children leave the nursery they are mere hot-house plants and it takes a long course of out-of-door sports to inure them to exposure.

These seeds sown in the nursery frequently develop later in life so that it is not an uncommon observation for college youths who led an active athletic life during their academic course to be attacked with phthisis when they settle down to the business of life, the tuberculosis having been kept in abeyance only by the out-of-door exercise which they enjoyed at college.

THE OPERATION FOR DEVIATION OF THE NASAL SEPTUM.

DR. ARTHUR W. WATSON, Philadelphia, believes that of many operations which have been devised for the relief of this condition none have as yet proved entirely satisfactory because the fact is lost sight of that a deviated septum is longer than a straight one and no provision is made for the reduction of the amount of tissue. The first step, therefore, in the operation, should be to reduce the septum to a size that will fit into a straight line between the points of attachment of that portion of the nose. This can be accomplished by removing a portion of tissue in the general line of deviation. If the deviation is horizontal an elliptical piece should be removed by incisions gradually convergent at either end. If the line of deviation is vertical a triangular, or wedge-shaped piece, should be cut out, the apex being upward and extending as high as possible, and the base reaching to near the base of the septum where it may be joined by a horizontal incision. Where both forms of deviation are met with in the same case, both forms of incision should be

used. The excised portion should always include the protruding angle, and the amount of tissue to be removed can be estimated by the eye. It is important to avoid cutting the mucous membrane on the side opposite the incision as the membrane helps to hold the edges in line and thus facilitates union and prevents perforation. The incision should be made on the convex side of the septum. To bring the body portion into line the crushing forceps may be used to advantage, either Adams' or Dr. Rau's.

The second part of the operation and the part which is most frequently neglected is the retaining of the septum in position. The author believes that one reason for failure in this operation is that the retaining force is not kept up long enough. From three to four weeks should be allowed for the healing of the cartilage. The best support for the cartilaginous septum is a steel pin with a flat ring head, the ring being covered by a piece of rubber tubing. The pin should be inserted from the concave side of the septum just back of its anterior edge and passed diagonally through to the other side, then across the vertical incision if there is one, and then back into the septum until the head lies on the septum within the nostril. Care should be taken not to produce a deflection in the opposite direction. This method leaves both nostrils free for respiration and cleansing. By padding the head of the pin, as described, no ulceration takes place and it may be worn for three or four weeks without discomfort.

Should the deviated bony septum require additional support a piece of iodoform gauze folded to the desired thickness may be placed between the septum and outer wall, at the point of deviation. As the bony portion unites more quickly than the cartilaginous the latter may be dispensed with in a week or ten days, leaving the pin to do the rest. In order to perform this operation properly the parts should be well illuminated and as free from blood as possible. Cocain anesthesia should be used in preference to ether.

INTUBATION IN THE ADULT; WITH SPECIAL REFERENCE TO ACUTE STENOSIS OF THE LARYNX.

DR. W. E. CASSELBERRY, Chicago, said although chronic stenosis of the larynx, especially of the syphilitic and tuberculous types, has received due attention in reference to treatment by intubation in the adult, the management of acute stenosis by the same means has received, as yet, but little notice. It does not suffice to assume that the adult may be dealt with exactly like the child, or that the treatment of acute stenosis with its associated state of helplessness and exhaustion, is identical with that of chronic stenosis. Important distinctions obtain both as regards the technique of the intubation and the possible scope of the operation. The six cases related embrace four of laryngeal diphtheria, one of acute edema of the larynx and one in which the stenosis was of obscure origin but probably also edematous. The diphtheritic cases all terminated favorably, but presented various difficulties in the performance of the intubations; notably in one, the necessity to intubate with the patient in a recumbent or semi-recumbent posture in bed, to accomplish which the best position was with the patient on the right edge of the bed and the operator standing to the patient's right, in which position one's right arm rises in front of the patient's mouth without awkward twisting of the operator's body. In another, at one time, spasm of the glottis, which was actually seen to occur in the laryngeal mirror, rendered a third effort necessary before the tube slipped into place. It was done under laryngoscopic view, by holding the tube firmly at the entrance of the larynx for a few moments, which excited cough and with it the opening of the glottis. All the cases showed some intolerance to the presence of the tube, as manifested by more frequent expulsion than with children. One case nearly succumbed from accumulation of viscid mucus, not in the tube but in the trachea and larger bronchi below and around the tube, which condition was at once suspended by the extraction of the tube. The case of acute edema of the larynx was complicated by chronic spasm of the masseters which prevented wide distension of the jaws. In consequence intubation failed, the patient being measurably exhausted by the two efforts made. Tracheotomy was performed, but the patient died just as the operation was completed, presumably from failure of the heart in connection with secondary edema of the lungs. Immediately, postmortem, the diagnosis was confirmed, and the feasibility of intubation demonstrated in acute edema of the larynx with a patient recumbent, possibly collapsed, but uncomplicated by "setting" of the jaws, by (after death) forcibly distending this patient's jaws when the tube could be passed and repassed with ease. The liability to pressure decubitus by the tube in acute edema of the larynx should be remembered and not too large a tube inserted.

The other case which was presumably one of edema of the larynx or of subglottic edema terminated favorably without difficulty.

The following conclusions as to technique are formulated:

1. For one accustomed to the use of the laryngoscope, intubation on adults is easier and more certain under its guidance; therefore, for a patient of adequate composure and able to maintain the sitting posture this method should be selected.

2. A patient lacking only composure, one whose inclination is to resist rather than to assist the operation, may be closely wrapped in a blanket to pinion the arms and legs, seated in a straight-back chair, the head inclined slightly backward, the mouth gagged and the finger used as a guide, as in children.

3. A patient lacking strength to move from bed and composure or strength for laryngoscopic insertion, should be placed close to the right edge of the bed so that the operator can stand at the patient's right side, the head and shoulders should be well raised by pillows, the neck moderately extended and the method otherwise fulfilled by the sense of touch. Kneeling on the bed in front of the patient is unnecessary.

4. A patient who is moribund, or nearly so, may have the tube inserted while in the recumbent position. The operator should stand at the patient's right, who should therefore be placed on the right side of the bed.

Spraying the fauces with a 5 per cent. solution of cocain facilitates introduction by whatever method and tends to lessen the liability to premature expulsion.

The extraction of the tube is especially easy under laryngoscopic illumination, otherwise it is done in accordance with the same principles as regards the position of the patient, as pertain to its introduction.

The author's posture method of feeding, subsequent to intubation, by inclining the patient's head and shoulders downward, in which position fluids may be swallowed without gravitating through the tube into the lungs, can be successfully used with adults, but naturally with more difficulty at first than with children, on account of unmanageable weight and size. It is best done by hanging the head and shoulders over the edge of the bed downward nearly to the floor. Otherwise, adults more readily than children may be fed upon semi-solids, as custards, stiff corn-starch and oysters, which will slide over the top of the tube without entering it.

Regarding the scope of intubation for acute stenosis in adults the four cases of laryngeal diphtheria herewith reported all of which terminated favorably, justify the conclusion that this operation may with advantage be substituted for tracheotomy in that disease.

Concerning acute edema of the larynx, the indications are not so clear. The operation is technically feasible in uncomplicated cases even when exhaustion is extreme, and I would consider a single attempt justifiable, provided, in order to guard against pressure decubitus the smallest size of the adult's set of tubes is first selected. When complicated by having the jaw "set" or by pharyngeal swellings, which might obstruct the top of the tube, either or both of which conditions may be encountered in cases of acute edema of the larynx, secondary to peritonsillar abscess, Ludwig's angina, phlegmonous angina, retropharyngeal abscess, etc., intubation is absolutely contraindicated and fruitless efforts thereat can only serve to intensify the exhaustion and suffering of the patient.

There are other conditions or acute exacerbation of chronic states which might be remedied by intubation. In a case of arthritis deformans which suffered an acute exacerbation involving the larynx, the dyspnea was so urgent that I expected for several days to be compelled to intubate at any moment. Traumatic edema of the larynx, as by scald, corrosion or fracture, might in suitable cases be treated in this way. Laryngismus stridulus or reflex spasm of the glottis, though rare in adults, might constitute another indication. Also edema of the larynx secondary to chronic syphilis or tuberculosis might come within the same category, since the edema may figure as an acute exacerbation, provoking sudden and urgent dyspnea.

The treatment of chronic stenosis of the larynx and trachea by intubation is not included within the scope of this paper.

LARYNGEAL PHOTOGRAPHY WITH THE AID OF THE ARC LIGHT.

DR. T. R. FRENCH, of Brooklyn, in his early experiments, made use of sunlight as the illuminating agent and the results were unsatisfactory, owing to insufficiency of illuminating power. He has recently called to his aid the arc light, and with the most gratifying results, not only with the larynx, but also with the naso-pharynx and posterior nares. As the distance between the camera and object was very short it was

difficult to adjust the light to the sensitive plate so that a proper focus could be obtained. The requisites therefore are a small diaphragm, a rapid shuttle, a very sensitive plate and a powerful light. The necessary outfit for the latter consists of a two thousand candle power arc light partly enclosed in a metal box, the anterior face of which bears a condensing lens at a distance of nine inches from the box, lens giving a focal distance of twenty inches. The lamp and accessories are fitted to a narrow board attached to a table with a device for raising and lowering the light. A shelf beneath the table carries the rheostat.

The matter of technic is the same as with the sunlight condenser (see *New York Medical Journal*, Dec. 13, 1884.) The pencil of light must be caught upon the head mirror some few inches inside the focal point. The focus is then found and with it, perhaps, a good picture. If the first effort does not succeed, the focus and necessary amount of light being known, there is no trouble in securing at the second sitting as many photographs as desired. No longer time is required with apparatus in good order than in making the usual careful laryngoscopic examination.

Dr. J. E. BOYLAN reported a case of

SPINDLE-CELLED SARCOMA OF THE NASAL PASSAGE.

He exhibited specimens and slides and said: At the time of introduction the patient, who had suffered from repeated and obstinate epistaxis and occasional acute pains in the head, presented a broad and flattened nose with a noticeable bulging under the margin of the left nasal bone. There was oozing of blood from the nostril on that side and the left passage was found to be totally occluded. Upon tilting up the tip of the nose, an irregular brown-red mass at once became visible, filling in the cavity almost to the anterior opening, which was found to be limited by the posterior nares behind and to spring from the side wall. Circumstances prohibiting a more radical operation, the growth was removed with the wire ecraseur in two sittings and the site of the attachment thoroughly curetted. Hemorrhage, which was quite profuse, was arrested each time by plugging with iodoform gauze. The removed growth appeared as a soft liver-colored tumor of irregular surface about the size of a hen's egg, having had an attachment about an inch and three-quarters long and having apparently originated in the inferior turbinated body. Expert microscopic examination showed the growth to be a spindle-celled sarcoma. A year from the date of operation inspection of the patient developed no signs of recurrence. May 10, 1895, twenty-two months after date of operation, patient announces by letter that he finds himself without symptoms of recurrence and in excellent health. The case is offered as a contribution to the accumulating number of those which tend to modify a hopeless prognosis of sarcoma of the nasal passages. Twenty-one cases taken from the literature since Bosworth's tabulation are enumerated and their results referred to. In conclusion, the importance of publishing the subsequent history of cases operated upon, over a period of several years, is urged.

Dr. CHAS. M. SHIELDS, Richmond, read a paper on

NASO-PHARYNGEAL FIBROMATA,

reporting two cases and exhibiting specimen and slides. He said the first occurred in a white man, aged 23. The tumor was attached to the vault and left lateral wall of the pharynx and completely filled the post nasal space. It extended also through the left nasal space to the anterior orifice and was attached for half its length to outer wall of the nose. It crowded the septum to the right to such an extent as to close that nostril. Nasal respiration was completely stopped. He presented the typical "frog face" and had the "dead" voice. After injecting a 10 per cent. sol. of cocaine into the left nostril a filiform bougie was with difficulty worked through to the throat, and to its anterior end a piece of silk was tied which was in turn fastened to the sharply bent loop of a cold wire snare. By this means the loop was drawn through into the mouth and well rounded before being pulled back into the pharynx where it was adapted around the tumor with the finger of the left hand. For five hours the snare was screwed up when the wire broke.

The next day the loop of a galvano-cautery snare was drawn through in the same manner and dropped into the cut begun by the cold snare. It cut through in a few minutes and the piece drawn down and out of the mouth. Its base measured one and one fourth by one and two fifth inches. A second piece sending a projection into right nostril was also removed with the cautery snare and was about half the size of the first. Then that filling left nasal space was in like manner removed. After fourteen months the patient returned for examination and then small pieces were removed. These occupied position over site of original growth.

The second case was being treated at the time the report

was made and Dr. Shields stated as his reason for such early mention the fact that it occurred in a woman of the negro race. Nélaton, Gosselin and other early observers considered women to possess immunity, and Morell Mackenzie considered naso-pharyngeal fibromata rare in that sex; but we know that females are not wholly exempt. As regards race, however, Dr. Shields considered it unique, never having seen a case reported or occurring in a negro. Bosworth states that he has never seen a case reported in that race. The woman was 48 years of age. The tumor filled the entire post-nasal space, pushing the soft palate well forward. It was attached both to the vault and posterior wall of the pharynx. A piece cut from the lower part and examined microscopically showed it to be a true fibroma. It had begun to attract attention three years ago. The patient was otherwise in good health. Electrolysis was being tried but not with very encouraging results.

In the treatment of these tumors Dr. Shields thought that ligation, evulsion, the use of chemical caustics, the thermocautery, etc., were not worthy of consideration in comparison to the use of the hot or cold snare, and he was of the opinion that few, if any, cases now required the resection of the superior maxilla or any other preliminary operation removal through the natural passages being possible. As to the comparative advantages of the hot or cold snare, the size and location of the growths would usually determine; but usually he preferred the former. He used irido-platinum wire in the galvano-cautery snare, finding it more elastic and stronger. Some very hard, dense tumors could not be cut through with the cold wire, as is evidenced by reported cases of the wire breaking and as in the first case reported in his paper. With the cautery snare, we have an instrument which we can use with the certainty of its cutting through any growth and accomplishing in a few minutes what the cold snare may require hours to do. The current should be turned on for a few seconds and then the patient allowed a few minutes rest before heating the wire again. In this manner the wire never became so hot as to cause troublesome hemorrhage and the pain attending the operation is very much lessened. Finally, while removing the tumor every portion of the remaining bone is thoroughly cauterized, thus securing any benefit that may result from that practice.

TUBERCULAR INFECTION OF THE LYMPHOID TISSUE IN THE PHARYNX, WITH SOME REMARKS ON LARYNGEAL INFECTION.

JONATHAN WRIGHT said this paper was meant as an addendum to the paper read by him on the same subject last year. He repeated Dieulafoy's experiments in twelve unselected cases of inoculating guinea pigs with tonsils and adenoids which in each case were examined histologically and bacteriologically with negative results. The animal experiments made by Dr. W. H. Park also resulted negatively. Tubercle bacilli having been found by Strauss and others in healthy noses and throats, I am inclined to think that Dieulafoy's results were due, as Cornil suggested, to surface contaminations. Dr. Botey of Barcelona, has published results closely resembling Dr. Wright's in similar experiments. Dr. Chappell had a case of tuberculosis of the naso-pharynx following an operation for adenoids. Tissue taken from this and subjected to the same examinations as in the twelve unsuspected cases was found by Dr. Wright to contain tubercle and tubercle bacilli histologically, while Dr. Park, by animal inoculation, also obtained positive results. This goes to prove that Dr. Wright's methods were not at fault in the twelve cases that were supposed clinically to be non-tuberculous. In making sections of tissue taken from a tubercular larynx he met with indisputable evidence of the penetration of the intact epithelium by tubercle bacilli, but whether this is possible in healthy throats he is not prepared to say.

(To be continued.)

Herbert Spencer's Little Joke.—Herbert Spencer plays billiards rather well for a philosopher and he is never wholly sorry when he wins the game. Once, at the Athenaeum Club, he played fifty up with an antagonist who began by putting the red into the top pocket, and getting into position for the spot stroke, ran out without giving the author of the "Synthetic System" a chance of handling his cue. It was very provoking, and at last Mr. Spencer felt constrained to speak. "Sir," he said, "a certain ability at games of skill is an indication of a well balanced mind; but adroitness such as you have just displayed is, I must inform you, strong presumptive evidence of a misspent youth." *Golden Penny.*

THE

Journal of the American Medical Association

PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00

Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the ASSOCIATION living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, JUNE 6, 1896.

GYNECOLOGY AMONG THE INSANE.

When some twenty-four years ago DR. STORER published his little work calling attention to the need of gynecologic treatment for a certain proportion of the female insane, it was undoubtedly with better reason than could justify a similar appeal at the present time. His voice was then like one crying in a wilderness; now it would be but one of many clamorous ones, all proclaiming the importance, even the predominance, of the sexual element in the mental disorders of women. At the present time all and more than he asked for has been gained. Women physicians are being generally added to asylum staffs, with the special design that they shall attend to the gynecologic and special needs of the female inmates, and in some States their employment has been made compulsory by law. It would certainly appear that professional and public attention was sufficiently aroused, and that the necessity of further appeals no longer existed.

It is not very long since, however, that in one of the States of the Union, the gynecologic zeal of an asylum physician was rather summarily checked by higher State authorities who considered that the tendency was to overrun the proper limits in this regard, and that, in their capacity of supervising guardians of the insane, it was necessary to administer an official snub to the enthusiasm of the superintendent. The liability to one-sided and partial views is here, as everywhere, present, and it would be well if a judi-

cious conservatism could sometimes be applied to overrule in other cases than the one above cited. The operative furor, which is deprecated by so many prominent gynecologists and surgeons, is especially unfortunate when exercised on those who, from their mental condition, are incapable of acting for themselves in judging of their own needs. Extensive mutilating operations like castration, which, notwithstanding the statement of SPITZKA that it became obsolete many years ago, is still popular in some quarters, are particularly objectionable in this point of view, and some interesting legal questions might be, and to a certain extent have been, raised in regard to them. It would be better in any severe gynecologic operations, were it practicable, to follow STORER's original suggestion and have all such passed on by a consulting board of competent specialists, and as an additional precaution it would be well to have, as far as possible, full legal sanction for any procedure that may involve the risk of life or of the future well-being of the patient. The practice of castration for any phase of insanity alone, whether in male or female, without some organic disease of the parts that may justify it, has no sufficient weight of authority in its favor and is condemned by the experience of practiced alienists. The most evident advantage that it possesses is in the fact that it may serve a purpose in the prevention of the production of future degenerates, but this is hardly an argument that will be adduced in its favor in the present state of our civilization. For any other purpose it has hardly an excuse, as repeated experience has shown its insufficiency as a remedy for mental disease, which it more often aggravates than helps.

The claims that are made of the value of gynecologic procedures in asylums suggest sometimes a disbelief from their very extravagance. It is the duty of every physician who has to treat insanity to neglect no physical condition that may have any possible bearing upon the case, and diseases of the sexual organs fall as naturally under this head as any others. It may often happen that their continuance has an unfavorable effect, and their treatment should therefore certainly not be neglected. But in estimating its benefits a judicious caution should be observed, for in recent cases, in which alone it is likely to be actually curative, there are many other possible factors in a properly treated case. When we hear of its producing a good proportion of cures in old chronic demented of many years' standing, the question naturally arises whether the results have been adequately observed, or if so, whether the operation has been the curative factor, as every one of experience is aware that remarkable effects sometimes follow the most various and apparently inadequate causes. A change of residence, a severe spell of sickness, a local issue like a carbuncle or boil, has been followed in chronic

insanity by a temporary betterment, and sometimes even by a permanent recovery, and the same is true of surgical operations other than gynecologic ones. The advocates of a more general and active gynecologic treatment of the insane are in danger of overdoing their case: they attempt to prove too much.

There are some special reasons why a certain conservatism is advisable in this regard with cases of insanity which are evident to those who have had practical experience in hospitals for the insane, and the employment of female physicians as gynecologists does not entirely relieve the disadvantages of this special line of practice in such institutions. Certainly the tendency to greater conservatism, which is evident amongst the best specialists in general practice, should not be unshared by those who have to do with the insane. The rule should be that operative procedures of this kind are, with certain restrictions, justifiable in the insane under the same circumstances that they would be advisable or desirable in the sane; they are not excusable if performed simply for a supposed curative effect they may have on the mental disorder itself.

It would be interesting to have the true facts as to the cases of insanity that have been actually benefited by radical gynecologic operations as compared with those that have originated from or have been injuriously affected by the same. In view of the utterances of certain very high authorities in gynecology, as well as the general consensus of the best alienist opinion, it is a serious question whether the occasional excessive zeal in this direction is not an actual source of peril at the present time.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

This is the name of the old association of medical superintendents of asylums for the insane, founded in 1844. Recently they held a four days' meeting at Boston, Mass., which was largely attended and of more than usual interest. The president, DR. RICHARD DEWEY of Chicago, Ill., in his annual address discussed at some length the question of corrupt and fraudulent commitments and unjust detentions in insane asylums. Recently in certain districts much agitation of the public mind has been manifested, and the papers have created the impression that great wrongs were covered up in many asylums. DR. DEWEY found from a very wide inquiry and study of the alleged cases no basis whatever for such a fear. A certain number of ill-balanced, highly nervous persons, and paranoiacs have paroxysms of mania and melancholy and are unable to control themselves; these are committed to asylums; also a number of drug-takers who are clearly insane for the time. They recover in part very quickly in asylums, then claim to have been unjustly committed. Such men revel as martyrs, and seek to make the asylum and its

managers odious. Lawyers, newspapers and the public generally are credulous enough to accept their statements. Later, many of these cases become permanently insane and commit crime, but their previous history is forgotten. Not a single case of fraudulent commitment in any large or small asylum is on record. The oft repeated statements to the contrary are entirely without proof. The conditions requiring so much concealment and collusion are not possible in a public asylum.

DR. CHAPIN, of the Philadelphia asylum, followed giving the history of several cases which had been taken out on a writ of *habeas corpus* and found to be insane. He asserted that in his experience of over a quarter of a century he had never known of illegal detention of sane persons in asylums.

DR. McDONALD, the State Commissioner of Lunacy in New York, expressed the same opinion, and affirmed that the statements of lawyers in New York and other cities about particular cases were entirely unverified. Gynecologic operations in asylums were discussed at some length, and the opinion prevailed that they were not curative, and were only valuable as removing contributing causes. The thyroid treatment of catalepsy and other neuroses had been followed by good results. Among the notable papers were the following: "The psychic Influence of the night Season;" "Paraphasia and Word-deafness;" "Disorders of the muscular System in Insanity;" "Psychology of Idiocy;" and DR. HALL's address on scientific psychology. Other very excellent papers were read and discussed with unusual clearness.

The sneer that American superintendents of the insane are not as a rule scientific men, is flatly contradicted by the papers and discussions of their annual meetings. This Boston meeting brought out the fact, that in some of the eastern and western asylums elaborate psychologic studies and experiments are going on which promise the most important results. The old-time methods of housing the insane entirely from the economic basis and treating them in great classes is passing away. The delusion that any medical man can be a successful superintendent of the insane, exists in some States, and the frequent changes is always a sad loss to the interests of science and the asylums. Fortunately this is passing away, and most of the members of this Association, have been trained through a long period of service as assistants to the heads of asylums, where they remain a lifetime. A large number of the members of this Association have been managing asylums nearly all their professional lives and have become more familiar with the clinical side of lunacy than it is possible in any other way. This Association and its work should be better known among the profession. Its proceedings should have a wider circulation among the general medical public and in this way some of the misconceptions of insanity would be corrected.

THE ALCOHOLIC QUESTION.

The agitation of the question of the medicinal value of alcohol continues with increasing interest both in this country and Europe.

The impression prevails that much of this agitation is carried on by partisans on both sides, especially in this country. In a certain sense this is partially correct, and while many medical men have strong convictions concerning alcohol, there is a constantly increasing desire to ascertain facts that support or disprove present theories. In Europe the question is treated more coolly. The moderate drinker and abstainer join with equal interest to study the action of spirits, and examine the conclusions with scientific fairness. In this country we have the Medical Temperance Association, who affirm that total abstinence is the proper standpoint from which all studies of alcohol must be made. On the other side the committee of fifty, composed of teachers in colleges, ignore all questions of personal interest, and believe that the facts can be more clearly studied by moderate drinkers, and persons who have experience in the use of spirits.

The latter have begun some elaborate researches concerning the action of spirits; the former have confined themselves to clinical experience of daily practice and in hospitals. So far it is evident that many conclusions widely differing from the present theories are to be sustained, and that the rôle of alcohol in medicine must undergo a great revolution.

At the Atlanta meeting the question of the stimulant action of alcohol was denied, and some European experience cited in proof. This called out sharp protests and contradictions. The same thing occurred in Zurich at a meeting of the alienists and neurologists last fall. In this instance elaborate psychologic experiments with instruments of precision were put in evidence, and the opposition only questioned the meaning of the evidence, not the evidence itself. The program of the Atlanta meeting contained the title of twenty papers devoted to alcohol and inebriety, showing that this general subject is becoming very prominent in medicine. At the present time wide differences of opinion must prevail until more authoritative studies shall settle the facts. The denial of the stimulant and food value of alcohol is not sentiment or mere opinion, but is founded on evidence that is believed by many eminent men to be correct. On the other hand, the opposite conclusions supposed to be settled beyond question, and supported by experience of equally good men, should be open for re-examination without prejudice. The physician who from personal experience finds greater success in the treatment of disease without the use of alcohol, and the physician who depends upon it in certain cases as the best remedy known, are entitled to equal consideration. Protests against each other and denials

of theories take the subject out of the field of science and prove nothing. If alcohol has a medicinal value all new studies and researches will bring new proof and evidence. Reopening the question and submitting the facts to a new examination is not "fadism" or sentiment, but scientific. To suppose that any present theories of alcohol in medicine are settled simply because they are accepted by the general medical public, is not the spirit of the age. In reality, the position of alcohol in medicine is questioned by an array of facts that point to very different conceptions from those at present entertained. These facts are ascertained and presented by medical men both in this country and Europe, who are by no means "cranks" or "extremists" in any sense. The whole subject demands renewed study, and the theories held so tenaciously by some physicians require new facts to sustain them, something more than the conclusions of foreign experimenters of years ago. Clinical study and experience of more accurate character is required before authoritative theories can be supported as presumable facts. The discussion of this subject requires less dogmatism and broader reasoning, and more appeals to facts and less theorizing.

LIMIT TO POWER OF HEALTH OFFICERS TO
CONDEMN ICE.

Circumstances may exist which seem to demand quick and summary action for the protection of health and life, and in such a case an officer upon whom authority for the purpose is conferred will not be held responsible for a sacrifice of property which the exigencies of the situation appear to require. But no decision which it has found, the court of appeals of Colorado goes on to say, goes further than this, and, where the necessity for immediate action does not exist, a judgment condemning property must be the result of a trial before a regularly authorized tribunal, in a proceeding to which the person whose rights are to be affected is a party, and in which the burden of proving the charges is upon the complainant, and full opportunity is given to the adverse party to make his defense. In the case in which these general principles are stated, *Munn, Health Commissioner, v. Corbin*, the above court, April 13, 1896, holds void an order of the health commissioner for the seizure and destruction of certain ice condemned as impure and that every step taken by him in the proceeding in which the order was made, was in violation of law. It appears that the first notice of any kind ever received by the ice company from the commissioner was one that the ice had been condemned and its sale forbidden.

The next notice was a citation to appear before the health commissioner, and show cause why it should not discontinue its business in the city of Denver, and why ice brought by it into the city should not be destroyed. And at the subsequent "hearing" there

was no evidence introduced that the ice was impure or unwholesome, but, upon the admission of the ice company that the ice came from a certain lake, that the company sold it to its customers, and that it was the same ice which the bacteriologist of the bureau of health had examined and stated was infested with germs of a variety dangerous to health, judgment went that it be seized and destroyed. Here the court holds, proper notice was not given to the owner of the ice and this was not the kind of hearing to which the ice company was entitled. In justification of the health commissioner's proceedings reliance had been placed on a provision of a city ordinance that he might condemn or cause to be destroyed any fluid or substance intended for food or drink whenever he was satisfied that its consumption might be dangerous to health. But the court says it can not consent to a construction of such provision which would empower a man, merely because he is distinguished from his fellow citizens by the title of health commissioner, to go about the city giving orders for the destruction of property, whenever by some mental operation of which he alone is cognizant, he has concluded that its use might be dangerous to health. He must become satisfied of the noxious character of the property in a legal way, by the application of legal methods, and as the result of an investigation conducted in accordance with the rules governing judicial proceedings, of which due notice has been given to the owner of the property, and at which full opportunity is accorded him to resist the proposed action, and make his own defense. In so far as an ordinance may empower the health commissioner summarily to make a final and conclusive order for the destruction of property, except under extraordinary conditions, the court holds it is invalid, and no justification to the officer so proceeding. It also holds that if a state statute must be so construed as to commit the fate of property, regardless of surrounding conditions, to the arbitrary and irresponsible decision of one man, and so clothe him with an authority which might be used without limit for purposes of oppression, it is in violation of rights guaranteed by the constitution, and therefore void.

CORRESPONDENCE.

The Bracelin, A Chlorin Solution Only.

CHICAGO, May 26, 1896.

To the Editor:—In a recent issue of the *JOURNAL* I noticed that Dr. Martin Matter is again not only assailing Bracelin's bactericide, but indulging himself in a series of sinister-handed compliments concerning me personally. A wily but unscrupulous old lawyer at one time was giving what he termed "valuable pointers" to a younger member of the profession in handling a jury, which were as follows:

1. If the facts in the case are in your favor and the law against you, stick to the facts and say nothing about the law.
2. If the law is in your favor and the facts against you, stick to the law and disregard the facts.

3. If the law and the facts are both against you, ignore both and vigorously abuse your opponent and his client.

In this way you will take the minds of the jurors away from the merits of the case and stand a chance of getting a verdict in your favor.

Dr. Matter must have gotten some "pointers" from such a source. Let me assure him, however, that verdicts obtained in this way usually recoil upon their recipients.

He first assailed me and the remedy through the columns of the *Chicago Tribune*, in which he said: "His success will depend largely upon the gullibility of the public." He also drew a conclusion that is, at least, laughable, if not logical. He says: "They [meaning the bacilli] can not grow in the fluid itself, a fact which J. J. Russell has garbled from the report [Gehrman's] as evidence of its [the bactericide's] antiseptic power." He might equally assert that water is poisonous to rats, because they can not live in it!

After my reply was published and after I had exploded his "rat-in-water" illustration by showing the difference between the rat and the bacillus in its habits, customs, tenacity of life and peculiarities, and that what was death to the former was life to the latter, he seemed for the time to be quieted; but like the phoenix arising from its ashes, he again breaks out anew through the columns of the *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, where he feels safe in the thought that not being a physician I shall not be permitted to follow him.

But, Mr. Editor, as you are fully aware, there are certain ethics governing journalism as well as the practice of medicine, and, having opened your columns to the gentleman for, in my opinion, an unjust, uncalled-for and unreasonable attack upon Bracelin's bactericide and upon me personally as well, I ask the privilege to reply to him through the medium he has chosen.

As evidence of the germicidal power of Bracelin's Bactericide (which is chlorin) allow me to quote from a letter received by me from Dr. H. John Tillotson, who had used the Bracelin remedy very successfully in a typical case of diphtheria. He says: "I used the Bracelin remedy as directed, and it worked like a charm, as I had expected it would do. The membrane disappeared within forty-eight hours, and the child was practically well in three days."

Dr. Matter refers to me in his article as "the genial and enterprising agent," and says I am "one of the most remarkable men in this country." For these kindly mentions, although lacking in sincerity, I thank him. As sarcasm is not argument I proceed at once to the facts.

I am engaged in calling the attention of the *medical profession* to the merits of this chlorin method of treating diphtheria, scarlet fever and diseases of the respiratory organs, but especially to its almost infallible curative qualities and absolute prophylactic properties in cases of diphtheria. To prove its merits I have been supplying it to Chicago physicians, free of charge, and with what success let the scores of successful terminations, reported by physicians and published, answer. In doing this work all I ask is an impartial consideration at their hands.

The gentleman does not like this remedy, but it will be observed that he does not cite any case where it was used by him or any other physician and failure followed. I unhesitatingly say that the animus of his opposition to the remedy is prompted wholly by jealousy. It may be interesting to know that this remedy was used with his consent on a patient of his who was suffering from pneumonia; that both he and his consulting physician pronounced the patient beyond recovery; that although delirious and practically unconscious, within five minutes after the corrected chlorin vapor was put into his lungs he opened his eyes and said: "I can now breathe easier." From that time on inhalations were continued, the patient recovered rapidly and is now well and goes about telling his friends that the remedy saved his life. In fact it acted

so satisfactorily in Dr. Matter's better judgment that a few days thereafter he came all the way from the South Side to my office and asked for and received from me, gratuitously, an abundant supply of the remedy with inhalers, and assured me he would give it a good trial in several cases he had and report to me the results. If he used it all it must have been with success, or he would naturally have cited its failure as the real grounds of attack upon it in the JOURNAL.

It was not until after the mother, son and daughter of the Eppstein family had written me a letter thanking me for the service I had rendered in bringing to the aid of their physicians in the case the remedy which apparently saved their father's life. This letter of gratitude from the wife, son and daughter of Mr. Eppstein was published in the *Tribune* and afterward came to the notice of Dr. Matter, and it seems suddenly changed his good opinion of the merits of the remedy.

After saying that chlorin is totally absent he says: "I have myself verified the presence of a slight amount of hydrochloric acid and menthol in the air inhaled from it." So his chemical test is made by smelling the air inhaled from it. It is true that there is about one per cent. of menthol in it, put there to destroy the disagreeable odor of the chlorin. Let me assure you, Mr. Editor, that it does contain an abundance of chlorin, with a corrective.

He again refers to the alleged report of Dr. Gehrman of the City Health Department in order to make a point against the Bracelin remedy. In doing so, he even disregards the truth. As Dr. Gehrman has passively made contradictory statements, as a bacteriologist, in regard to this remedy, he will hardly thank his friend (?) for making him say: "It differs from all known antiseptics in one particular: The latter kill bacteria; but the bactericide does not." This would seem cruel, following what Dr. Gehrman said at a meeting held in the Health Commissioner's office on December 18th, in the presence of Drs. Cotton, Murdoch, Hawley, Bracelin, the Commissioner of Health and the writer, on being asked the result of his investigations by the Commissioner. He said:

"I am not prepared to say, so far as I have gone, that the vapor itself is a very strong germicide, but I will say that the liquid is very powerful and will kill Loeffler's bacilli in short order. I took five culture tubes containing serum which were all inoculated with the diphtheritic bacilli and subjected them to a treatment of Bracelin's liquid, each for one, two, five, ten and fifteen minutes respectively, and I found that the germs in all of the tubes were positively killed, except in the one that was exposed to the liquid for only one minute, and in that one I found life, but in the other four the bacilli were dead."

At the same meeting he further said: "I can see no possible danger in the inhalation of the vapor generated by the liquids constituting Bracelin's Bactericide."

For the purpose of prejudicing the profession against the use of this remedy, he is trying to connect it with a remedy misnamed "Omnicura" and says: "Under the fostering genius of Mr. J. J. Russell it has come to blossom like an octopus at the side of Omnicura." Permit me to say, emphatically, that there is not now and never has been, directly or indirectly, any more relation or connection between Bracelin's Bactericide and the so-called "Omnicura remedy" than there is between the Kleb's Loeffler bacillus and the Ferris Wheel; either in ownership, discovery, similarity of application or mode of introduction. Bracelin's remedy is the discovery of a way to use chlorin by Dr. Bracelin, a regular physician of twenty-one years' practice and in good standing in the profession. He asks physicians to give this remedy an impartial trial and thereby help him to prove what he claims, after which he will publish the formula for making the corrective by which he removes from chlorin its suffocating and irritating qualities while still preserving its therapeutic power.

As the best evidence of which the case is susceptible I will, in the presence of any gentleman who is sufficiently interested

to know the truth, take a bottle of chlorin solution and place a teaspoonful of it in the Bracelin Inhaler with the acid to liberate the chlorin and develop at once a gas which is impossible for any human being to inhale. I will then put in another teaspoonful of the nascent chlorin, thereby doubling the dose, and add to it a few drops of Dr. Bracelin's corrective which I will first put upon my tongue to prove its harmlessness and render it as capable and as pleasant of inhalation almost as the air we breathe. This kind of proof should satisfy the most skeptical.

In a sneering way he speaks of the enduring fame that will henceforth attend the physician who writes a letter to *The Tribune* glorifying the Bracelin cure and says his name will be handed down to future generations. Whether it will be so far reaching into the dim vista of coming generations I can not say, but I firmly believe in the perpetuity of the names of those who show an honest disposition to benefit the condition of their fellow-men.

Should any Chicago physician desire to test this preparation, clinically, I shall be pleased to furnish it to him gratuitously.

J. J. RUSSELL.

What the Good Book Says about Doctors.

SAN DIEGO, CAL., May 26, 1896.

To the Editor:—In these days of Christian science, substitution(?), faith healing, proprietary medicines, *et id genus omne*, it is refreshing to recall the language of our ancient friend Ecclesiasticus, quoted verbatim from the 38th chapter of his sensible treatise. (I know not why it was relegated to the apocrypha.) Hear him.

1. Honor a physician with the honor due unto him for the uses which ye may have of him; for the Lord hath created him.

2. For of the Most High cometh healing, and he shall receive honor of the King.

3. The skill of the physician shall lift up his head: and in the sight of great men he shall be in admiration.

4. The Lord hath created medicines out of the earth: and he that is wise will not abhor them.

5. Was not the water made sweet with wood that the virtue thereof might be known?

6. And he hath given men skill, that he might be honored in his marvelous works.

7. With such doth he heal (men) and taketh away their pains.

11. Give a sweet savour and a memorial of fine flour and make a fat offering as not being.

12. Then give place to the physician, for the Lord hath created him; let him not go from thee, for thou hast need of him.

14. For they shall also pray unto the Lord, that he would prosper that which they give for ease and remedy to prolong life.

Very sincerely yours,

C. M. FENN, M.D.

Sero-therapy—et id omne genus.

SAN FRANCISCO, CAL., May 23, 1896.

To the Editor:—The announcement in your issue of May 16 (quoted from *La Semaine Médicale*), of two cases of mania cured at Montpellier by injections of serum from a recovered maniac, suggests boundless expectations from sero-therapy and other new agents. It is presumptive that insanity is a germ disease, and that bacteriologists will soon differentiate its specific microorganism. At present we can only speculate whether homicidal and suicidal mania, kleptomania, pyromania, dementia, etc., are due to the same or separate microbes; but obviously one ought to choose cultures from cases resembling the particular type of insanity under treatment.

We may anticipate also the early discovery that the vices of

gambling, drunkenness, unchastity and mendacity (already supposed to be evidence of mental deterioration) are due to specific microbes and amenable to sero-therapy. The only difficulty would be in determining whether the supply be derived from a subject thoroughly cured: but we may hope that full guarantee may be afforded by some further application of Roentgen's ray, or by the aid of thought-transference and mind-reading.

With thorough development of therapeutics on the lines here indicated, it is evident that our noble profession will soon depopulate asylums, reformatories and penitentiaries, and retire into innocuous desuetude both the clergy and the Salvation Army, or divert them into new fields of activity. Meanwhile surgeons must not allow physicians to absorb all the new glory of the healing art, and I am sure they will not be found wanting. For instance, when sero-therapy has done its work in reforming a prostitute, the surgeon is expected to restore by a plastic operation the original credential of virginity.

Finally, the physician will not neglect his own interest in this work of benevolence, but will always be provided with the serum of a reformed swindler for administration to his patients, and thereby secure prompt payment of his bills.

~ S. S. HERRICK, M.D.

A Leprosy Congress.

NEW YORK, May 27, 1896.

To the Editor:—Regarding an International Congress for the prevention of leprosy, as proposed by Dr. Goldschmidt, I have the honor to transmit the following letter:

"HONOLULU, HAWAIIAN ISLANDS, April 28, 1896.

"Dear Dr. Ashmead:—At a meeting of the Board of Health held on the 22d inst., I presented your correspondence with Dr. Goldschmidt in regard to the International Medical Congress for the discussion of leprosy. It was decided to inform you that the Hawaiian Government takes deep interest in the efforts of Dr. Goldschmidt to hold a congress and that the sending of a delegate will be considered, if an invitation is received.

"Sincerely yours, L. F. ALVAREZ, M.D.
"Bacteriologist to the Hawaiian Board of Health."

Very truly yours, ALBERT S. ASHMEAD, M.D.

PUBLIC HEALTH.

Cholera Vibrio in Hen's Eggs.—Golowkow announces in *Wratsch*, No. 7, that he has demonstrated beyond a doubt that the cholera vibrio can penetrate the shell and enter hen's eggs.

The Illinois State Board of Health Auxiliary Sanitary Association held its third annual meeting in Springfield, Ill., May 22 and 23. About thirty members were in attendance. Dr. B. M. Griffith presided. Dr. Arthur Reynolds, of Chicago, read a paper on "The Duties of Local Boards of Health as Instructors of the Public." Prof. A. W. Palmer, Professor of Chemistry at the University of Illinois, read a paper on "Water Analysis and the Means Provided by the State University for making Analysis of the Water Supplies of the State." Papers were read by Assistant Attorney General M. L. Newell, Dr. C. W. Oleson, of Lombard, Dr. A. G. Patton, of Monmouth, and others. The following officers were elected for the ensuing year: President, Dr. B. H. Griffith, Springfield; Secretary, Dr. John W. Scott, Springfield. The President will appoint Vice-Presidents from each congressional district.

Submersion by Sewage Causes Fatal Septicemia.—According to the *Medical Press and Circular*, a drain laborer lost his life in an unusual manner. His exposure occurred while he was engaged in examining a drain which had become blocked. In doing so, he took a large bar and broke the drain pipe near to the spot where he considered the blockage to be. No sooner had this been done than the retained sewage was suddenly, and with force, discharged into his face and over his clothing,

some even entering his mouth. For some days afterward, he continued to do his work without complaint. Ultimately, however, throat symptoms began to develop, and he was admitted into University College Hospital, where he soon died. The evidence of the house surgeon was to the effect that death took place from acute blood poisoning, the result of inhaling the products of highly decomposed sewage. While in the hospital the man asserted that he could still taste the sewage matter which had gone into his mouth.

Prompt Notification to the Interior.—The Secretary of the Treasury has ordered that after arrival at a quarantine station of a vessel upon which there appears, or has appeared during the last voyage, a case of cholera, smallpox, typhus fever or plague, and after quarantine measures provided by regulations of the Treasury Department have been enforced and the vessel given free pratique, it is ordered that notification of the above-mentioned facts be transmitted by the quarantine officer to the commissioner of immigration at the port of arrival, whose duty it shall then be to transmit, by mail or telegraph, to the State health authorities of the several States to which immigrants from said vessel are destined, the date of departure, route, number of immigrants, and the point of destination in the respective States of the immigrants from said vessel, together with the statement that said immigrants are from a vessel which has been subject to quarantine by reason of infectious disease, naming the disease. This information is furnished to State health officers for the purpose of enabling them to maintain such surveillance over the arriving immigrants as they may deem necessary.

Not to Marry in Connecticut.—A law was passed in Connecticut in 1895, that no man and woman, either of whom is epileptic, imbecile or feeble-minded, shall intermarry or live together as husband and wife, when the woman is under 45 years of age. The penalty for violating or attempting to violate this enactment is imprisonment not less than three years. Any selectman or any other person who shall advise, aid, abet, cause, or assist in procuring, or countenance any violation of the foregoing provisions, or the marriage of any pauper when the woman in such marriage is under 45 years of age, shall be fined not less than \$1,000, or imprisoned not less than one year, or both. Every man who shall carnally know any female under the age of 45 years who is epileptic, imbecile, feeble-minded or a pauper, shall be imprisoned in the State prison not less than three years. Every man who is epileptic who shall carnally know any female under the age of 45 years, and every female under the age of 45 years who shall consent to be carnally known by any man who is epileptic, imbecile or feeble-minded, shall be imprisoned in the State prison not less than three years. But nothing contained in the above shall be construed as affecting the mutual relations of any man and woman lawfully married.

Discriminating against Medical Colleges.—At the last session of the Iowa General Assembly the act relating to the State Board of Health—the medical members of which form the State Board of Medical Examiners—was amended as follows: "But no one of the seven physicians appointed shall be an officer or member of the faculty of any medical school in this State, and the Governor shall have the power to remove any member of said Board for good cause shown." Against this legislation, the secretary of the board, the veteran Dr. J. F. Kennedy, enters a vigorous protest, on the ground that it is an unjust and unnecessary discrimination against an honorable, competent and intelligent class of physicians, who are citizens and tax-payers. It declares that all such, however well qualified in every other respect, if they are connected with a medical college of Iowa, are unfitted to act as members of the State Board of Health, or to assist in determining what curriculum of study or facilities for teaching shall be required of medical

schools. The law is unique, Iowa being the only State whose legislature has declared that a professorship in a medical college unfits its possessor for membership in the State Board of Health. Dr. Kennedy adds: "This law has greatly encouraged the enemies of medical colleges. It must be apparent to all that there is in Iowa, and has been for two or three years, a growing prejudice against medical colleges and their students—a prejudice greatly intensified by some occurrences in this city last winter. To all who would gladly see the medical colleges of Iowa reduced in number, if not entirely wiped out, this legislative thrust at their teachers is significant and hopeful."

Progress of Water Filtration.—Experience is rapidly accumulating in favor of the filtration of all water supplies for large cities. In such places as The Hague (3.4), Berlin (4.0), Rotterdam (4.8), Breslau (6.1), Dresden, (6.9), Amsterdam (8.5), the prevalence of the acute intestinal diseases has been greatly lessened since resorting to filtered water, and the typhoid fever mortality has been reduced to the figures given in parentheses, which are per one hundred thousand of population. In London, with 83 per cent. of its supply filtered from the Thames and the Lea, there has been a similar reduction. Professor Frankland, F.R.S., in a recent address on the water supply of the great metropolis, points out the efficacy of complete filtration, and maintains that, as a factor in the production of a pure water supply, perfect filtration is of greater importance than the purity of the source from which the water is drawn. "The line of demarkation between the past and the present water supply of the metropolis is . . . to be drawn, not when the intakes of the river companies were removed to positions beyond the possibility of pollution by the drainage of London, but must be drawn at the time when efficient filtration was finally secured and ever since maintained, that is to say in the year 1884." His conclusion is that "for half a century, at least, we have at our doors, so to speak, an ample supply of water, which for palatability, wholesomeness and general excellence will not be surpassed by any supply in the world." And this notwithstanding, as *The Hospital*, May 16, notes that just at the present moment the innocence and harmlessness of London water is being seriously called in question by various metropolitan sanitary authorities.

Filtered Water Supply for Cincinnati.—The plans for an improved water supply for the city of Cincinnati provide for taking water from the Ohio River some distance above the city and above the mouth of the Miami River. The water is to be purified by sedimentation and sand filtration. Large reservoirs will be constructed which will allow the water to stand six days for sedimentation before it is delivered to the filters. There will be twenty-two acres of filter beds constructed independent of each other, so that a daily bacteriologic examination of the delivery of each bed may be made. The filter beds will be open, but are planned so that they may be covered if this is found necessary on account of ice. The estimated cost of the work is six and a half millions of dollars. Mr. John W. Hill, C. E., president of the Engineering Commission which has prepared these plans, has collected the statistics concerning typhoid fever mortality and the water supply of a large number of places, from which the following facts and figures, as to deaths from typhoid per 100,000 of population and source of water supply of 31 American cities, are worthy of study:

Brooklyn, impounded and well water, 19.0; New York, impounded from the Croton and Bronx Rivers, 20.4; Davenport, filtered from the Mississippi River, 21.4; New Orleans, rain-water from tanks and cisterns, 21.4; Boston, Lake Cochituate and Sudbury River, 32.6; Detroit, Detroit River, 33.8; Dayton, driven wells, 36.0; Buffalo, the Niagara River, 39.2; Providence, the Pawtucket River, 39.2; Covington, the Ohio River, 39.4; San Francisco, impounded from mountain streams,

40.2; Minneapolis, the Mississippi River, 45.4; Baltimore, Lake Roland and Gunpowder River, 45.8; Newark, impounded from the Pequannock River since April, 1892, 45.8; St. Louis, the Mississippi River, 47.0; Newport, Kentucky, the Ohio River, 47.5; Philadelphia, the Schuylkill and Delaware Rivers, 48.2; Denver, the South Platte River, 48.3; Cleveland, Lake Erie, 49.2; Cincinnati, the Ohio River, 52.4; Quincy, Illinois, filtered from the Mississippi River, 58.0; Knoxville, filtered from the Tennessee River, 61.9; Jersey City, the Passaic River, 75.0; Washington, the Potomac River, 76.6; Louisville, the Ohio River, 79.4; Chattanooga, the Tennessee River, 80.0; Chicago, Lake Michigan, 84.0; Pittsburg, the Allegheny River, 91.7; Lowell, driven wells and the Merrimac River, 92.4; Atlanta, filtered from the Chattahoochee River, 92.8; Lawrence, filtered from the Merrimac River, 96.2. These rates are exceeded only by Alexandria and Cairo in Egypt, supplied by the river Nile, and the figures of which in 1894 were 100 and 135 per 100,000 respectively.

Cholera in Alexandria.—The *British Medical Journal*, May 16, states the following:

"Notwithstanding every effort of the sanitary authorities, cholera is increasing in Alexandria, and there is now some danger of its spreading to the provinces, where it had been completely stamped out. It has already broken out in villages in the neighborhood of Alexandria. In a communication received from our Cairo correspondent, we are informed that very great difficulties are met with in dealing with the outbreak, partly from the insanitary condition of the town, but largely from the hostility of an ignorant press, which had throughout the winter not only denied that the disease officially pronounced to be cholera was cholera at all, but had excited the population to oppose the measures necessary for the control of the disease. In 158 cases which have occurred since December, 136 of which have been fatal, the bacteriologic evidence has been conclusive. The water supply of the town is unfortunately drawn from a canal, and is at any moment liable to contamination, for already cases are occurring along the banks of the canal. The position is clearly one to cause considerable anxiety."

The official reports received by the U. S. Marine Hospital Service, May 19, give the following mortality: Alexandria, 28; Cairo, 24; Tura, 1.

National Conference of State Boards of Health.—The eleventh annual National Conference of State and Provincial Boards of Health will be held in the city of Chicago, June 10, 11 and 12, inst. The program embraces addresses of welcome by the Governor of the State and Mayor of the city, with response by Dr. J. N. Taylor, of Indiana, President of the Conference; report of the Committee on Vaccine Farms, and discussions of the following topics: What substantial progress is being made in sanitary work in the several States and Provinces? What should be done with immigrants who arrive on vessels infected with smallpox? Is it not possible to have uniformity of laws and rules for the transportation of corpses and does not sanitary science provide sufficient knowledge and skill to transport a corpse dead of any disease in such manner as to be safe to the public? How to obtain the vital statistics of a State? How may cities obtain potable water when compelled to depend upon rivers polluted by sewage for their supply? A National Department of Public Health; Is such an institution desirable, and what should be its functions and its relations to State Boards of Health? What precautions should be taken on railroad trains to prevent spread of tuberculosis? Is it necessary to use isolation, placarding, or other quarantine restrictions in the prevention of typhoid fever? Should the State and Provincial Boards of Health have supervision, and be responsible for the purity of antitoxins manufactured or used within their respective States or Provinces? How far shall the State Board of Health have control of the manufacture and sale of milk products, especially the daily milk supply? What are the proper limits to the functions of State Boards of Health in dealing with questions of local sanitary

administration? The omnipresent hog: Should the flesh of hogs fed in and about slaughter houses be used as food for human beings? On Wednesday evening the conference will be addressed by the Hon. Lyman E. Cooley, of the U. S. Deep Waterways Commission, on the sanitary aspect of the great Chicago Drainage Channel, and the following day the delegates will be "personally conducted" by the Sanitary District Trustees on a tour of inspection of the channel, to be supplemented on Friday by a visit to the cribs, intakes and tunnels of the city water supply, which it is hoped may be made fit to use, in some remote future, by the completion of the drainage undertaking.

St. Louis.—The terrible calamity which has befallen the city of St. Louis is not to be measured by the tale of the dead and wounded thus far compiled; still less by the money value of property destroyed or the losses involved in interruption of business and suspension of productive industries. Serious as these are—probably exceeded in magnitude only by the similar results of the great fire of 1871 in Chicago—the ultimate effects on health will dwarf them into relative insignificance.

Last year St. Louis had a death rate of 16.48 per thousand on its estimated population of 570,000. In 1871 the death rate of Chicago was 20.87 per thousand; but in 1872 it rose to 27.67 and the total deaths increased from 6,976 to 10,156 in a population increased by probably less than 30,000. The actual increase of the death rate was 32.6 per cent. And the causes of this enormous increase were to be found in the overcrowding of the remaining dwellings, in the exposure, impure water and contagion imported by the multitudes who flocked to the city for employment in the work of rebuilding. Typhoid fever and smallpox prevailed beyond any previous record; infant and child mortality was frightful; cholera infantum was 25 per cent. higher than the highest recorded in fifty years. Nor did these baneful results end with this class of diseases. In 1873 the deaths from the nervous diseases shot up 58 per cent. beyond the average previous to 1871, the result of the profound shock of those fateful few hours and of the intense strain of the months that followed.

With the effects of the St. Louis disaster on the nervous system there is little that the health authorities can do. But it behooves them to use every effort to limit the causes of directly preventable diseases. On the 16th one of the great national conventions will assemble in the stricken city; thousands of visitors will be attracted, both by the convention and by the city itself. These must be protected from the conditions which now afflict the citizens and guarded against aggravating those conditions. The Health Department will have its hands full. Fortunately, it is well equipped, thoroughly organized and under the charge of a competent medical man of first-class executive ability. Dr. Max Starkloff may probably be relied upon to do at least as effective work as if he were a "business man" who knew nothing of sanitary matters and public hygiene. And he will be loyally aided by the entire medical profession of the city.

Health Reports.—The following health reports have been received in the office of the Supervising Surgeon-General, U. S. Marine-Hospital Service:

SMALLPOX (UNITED STATES).

Louisiana: New Orleans, May 16 to 23, 14 cases, 6 deaths.
Tennessee: Memphis, May 23 to 30, 2 cases.
Indiana: Indianapolis, May 29, 1 case.

SMALLPOX (FOREIGN).

Birmingham, May 9 to 16, 1 case.
Buda Pesth, April 30 to May 6, 1 case, 1 death.
Cairo, April 23 to 29, 5 deaths.
Cardiff, May 9 to 16, 1 death.
Corunna, April 25 to May 16, 5 deaths.
Dublin, May 9 to 16, 1 case.
Genoa, May 9 to 16, 4 cases.
Licata, May 2 to 9, 1 death.

Montevideo, April 4 to 11, 2 cases; April 18 to 25, 1 case, 1 death.

Moscow, May 2 to 9, 1 case, 1 death.

Naples, May 9 to 16, 6 cases, 4 deaths.

Osaka and Stio, April 25 to May 2, 17 cases, 1 death.

Prague, May 2 to 9, 4 cases.

Rio de Janeiro, April 25 to May 2, 7 cases, 1 death.

Sunderland, May 2 to 16, 1 case.

Trieste, May 2 to 9, 1 case.

Tuxpan, May 2 to 9, 4 deaths.

Warsaw, April 18 to May 2, 5 deaths.

YELLOW FEVER.

Havana, May 14 to 21, 12 cases, 4 deaths.

Rio de Janeiro, April 25 to May 2, 70 cases, 60 deaths.

CHOLERA.

Egypt: Alexandria, April 23 to 29, 6 deaths; May 19, 28 deaths; Cairo, May 19, 24 deaths; Tura, May 19, 1 death.

SELECTIONS.

The Valedictory Address of Prof. Theophilus Parvin delivered at the Commencement of the Jefferson College, abounded in practical suggestion and was a strong appeal in favor of a higher ethical standard among physicians in their intercourse with each other and their patients. He urged his hearers to be manly, and said that the possession of stature is no proof that the psychic nature corresponds. As a marked exception to the rule that "tall men had ever empty heads," as Bacon believed, he exclaimed, "There rises before me, in all his grand proportions, with his great brains, his dignity, and commanding presence, the most eminent of all the graduates of Jefferson, and the greatest of her teachers, whose professional peer can not now be found upon the continent—Samuel D. Gross." He referred to melancholy cases occasionally encountered, of moral osteomalacia, which he denounced as deplorable illustrations of men unworthy of confidence, and he warned his hearers against time-servers and human jelly-fishes, or molluscs. In speaking of this resemblance of some men to the lower animals he said:

"The monkey, the lion, the dog, the donkey, the cat, the tiger, the vulture, the weasel, the parrot, with 'the rest of the honorable company that came out of Noah's ark,' may be found among human beings. Dr. Johnson has truly described certain men as 'screech owls,' and some remember the fierce rhetorical contest between two public men in our country, each of splendid ability—Conkling and Blaine—one of them calling his antagonist a peacock; the retort was that he was a turkey-gobbler. I have a medical friend, ready in his recognition of these resemblances, who finds in the form and features of some men a bloated bull-frog. The ape and the peacock are not unfrequent degenerations from the normal type, the one in face, the other in action. The fox is in some cases plainly revealed. The lessened separation of the small, twinkling eyes, the sharpness of the nose, and the furtive expression indicate the vulpine face and character. The fox-man has the cunning and audacity of the fox; he seeks to impress people with his superior knowledge and ability, keeps his name before the public as much as possible, looks so wise, is artful in all his words and ways. He is little scrupulous in taking a brother-practitioner's patient, and preserves no golden silence as to the supposed or real errors of another. He generally has some useless fad which he never fails to impress with the solemnity of the moral law upon a client, and endeavors to make a patient believe she is wonderfully beautiful, or gifted with extraordinary intellect—she may be princess or empress, Juno or Venus, or Madame de Stael. If an operator, he does not hesitate to invite laymen to witness his skill, or make known his achievements to a newspaper reporter."

He next referred to some tendencies and practices, which he considered highly injurious to the welfare of the profession at

the present day: "Not only the prevailing love of wealth, but the over-crowding of the profession and the multiplication of specialties and specialists, are causing a moral deterioration of the profession. Medicine is becoming more mercenary, more of a trade. Means of advertising are employed by some specialists that bring uncompensated evil. Here is a doctor that sells his patients to get other patients in return; or here is a specialist who divides his fee with the physician who sends him a patient. How can merit hold its place against such venality? I hope the practice I denounce is not common, nay, I do not believe it is, but it ought not to exist all. Why is there not lifted up from the leaders some adequate denunciation of the accursed conduct? Alas! in regard to some of these leaders, one is compelled to ask in sorrow, *Quis custodiet custodes?* Look at the means used to advertise, the soliciting of patients by over-zealous kindred or friends, or paid workers, at many contributions to medical journals, simply and solely advertisements, at plagiarisms, the use of instruments, or methods that have been adopted from others, either without any or only insufficient acknowledgment; and the pirates never punished, but treated with like forbearance as the dead."

"There must be a healthier public professional sentiment, so that just punishment shall be awarded transgressors, whether thieves of patients or of reputation, of places, or of power, or of papers, when the slanderer shall meet his due in general professional contempt, especially when he plays piety for pecuniary reward, and banks upon pretended religion." The character of the perfect gentleman was held up as worthy of imitation by every physician.

"It is impossible for avaricious men and misers to be gentlemen, for avarice is selfishness, a pure egoism, while in the character of the gentleman there is necessarily no small element of altruism. The gentleman may wear a calm exterior, but feel most profoundly, and if his feelings are deeply touched by insult, by ingratitude and treachery, be prompt to subdue them and bear the wrong in silence if redress be impossible. He may be thought cold, but just as a rippling stream covered with film of ice flows on its serene way, the music is by no means abated. Nay, more, this man so reserved, apparently so cold and distant, this gentleman whose seeming indifference chilled you, if only there be congenial companionship, if warmed by the sun of love, touched by the fingers of affection, is no longer distant and reserved, but frank, outspoken, full of all genial life, just as the statue of Memnon broke forth in richest melody when touched by the rosy fingers of Aurora. Very often the true gentleman is misunderstood and misrepresented because so many can not comprehend him. So many doctors fail to cultivate gentlemanly manners, gracious courtesies, loving sympathies. Even sometimes their manners are so coarse, they are so devoid of feeling, that they are called, not gentlemen, not even men, but brutes. Heaven save you from ever justly receiving such a name! Yet these brutes are sometimes very much in evidence, very much in the public papers, and, it may be, happy in their coarseness and vanity, so that I often think Rousseau was mistaken when he wrote that if there ever was a man upon earth made happy by his vanity, it is past a doubt that he was a fool. Manners tell what a man is. Spenser wrote:

True is, that whilom that good poet said,
The gentle mind by gentle deed is known:
For a man is by nothing so well bewrayed,
As by his manners; in which plain is shown
Of what degree and what race he is grown.

"Not only be a man, not only be a gentleman, but likewise be a student—a student of medical literature, so that you may keep abreast of all true progress: but especially study your cases. Lord Bacon thought that medicine had not advanced, in part, for this reason: 'The discontinuance of the ancient and serious diligence of Hippocrates, who used to set down a narrative of the special cases of his patients, and how they proceeded, and how they were judged by recovery or death.' Let not this reproach fall upon you."

Dr. Parvin next inveighed against excessive drug giving, and said: "When I was a boy, I read as the motto of a newspaper published at Washington, 'The world is governed too much;' and for some time past my motto has been, 'The world is drugged too much.' The great majority of human beings eat two-thirds more food than they need for the best physical and intellectual life; and when the stomach so often rebels against such excess of supplies, and indicates that it wants rest, we ply the tonics and pamper the patient with daintily contrived dishes, tempting to do the worst thing. A great part of fashionable cookery for the sick—the fad of the present day—is mischievous, and is calculated to prolong sickness rather than promote convalescence. I wish you would read the recently published book by Dr. George S. Keith, 'Plea for a Simpler Life,' and I am quite sure that, observing its precepts, your own lives will be longer and stronger, and your patients will not be made drug-stores."

In conclusion, he urged the recent graduates to aim at high ideals:

"Not only study medicine, but also do not neglect literature and philosophy. The senior Gross once said that the doctor who knew medicine only, did not know medicine. Just now, too, the study of philosophy commends itself especially to the physician, for there is a strong movement toward idealism, and human thought is becoming more and more idealistic, while materialism, it is to be hoped, passes away never to return. Philosophic, moral and social questions are affected by this influence directly, and medicine will be. You can not be a doctor, a learned man, without giving study to the prevailing philosophy of the day. Still less can you ignore the question of religion. The longer I live the more tolerant I become as to differences of religious beliefs, and the less I think of creeds, the more of character and conduct—a man's profession is not half so important as his action—alas, they are very often in conflict." According to a beautiful legend the robin "plucked a thorn from the crown of thorns, and ever after its breast has been stained with a blood purer than the blood of the knightly Charlemagne; and so you can pluck thorns from bleeding brows, help the weary ones to bear the cross, and lessen some of the *Misereeres* that are forever ascending, ascending from the sorrow-stricken fields of earth to the infinite and peaceful heavens. What is popularly called success may fail some of you, but if the failure comes after honest, heroic effort, living only an honorable life and just, then you sink to foundations of higher honor.

'Children of God! inheritors of heaven!
Mourn not the perishing of each fair toy;
Ye were ordained to do, not to enjoy,
To suffer, which is nobler than to dare.
A sacred burthen is the life ye bear,
Look on it, lift it, bear it solemnly,
Stand up and walk beneath it steadfastly;
Fail not for sorrow, falter not for sin,
But onward, upward, till the goal you win,
God guard ye, and God guide you on your way.
Young pilgrim warriors who set forth to-day.'

BOOK NOTICES.

The Stomach, its Disorders, and How to Cure Them. By J. H. KELLOGG, M.D. Illustrated. Modern Medicine Pub. Co. Battle Creek, Mich. 1896. 8vo, cl., pp. 370.

This is a popular work, intended for the general public, although the author disclaims an attempt "to displace the wise family physician, but rather to aid and abet him in the management of a class of maladies which requires, perhaps more than all other the thorough coöperation of the patient." This sounds well, and the general hygienic directions are excellent and well told—but we doubt if the chapters on treatment are judicious in a book of this character. Especially in cases where the patient can not get along without a prescription, or some appliance. Lavage as recommended, p. 196, should surely be performed under the direction of a physician, rather than by the patient himself, and if the author desires the book to have more of a scientific character, he would do well to lessen the amount of advertising worked into the text for the Battle Creek Sanitarium Health Food Company, page 226. The products of that company may indeed be excellent, but are there not others? It is to be noted also that all medical preparations

and appliances recommended in the text are to be procured from the Sanitarium Company or the "Modern Medicine" Co. These palpable advertisements bring an otherwise valuable book very close to the border line, where regular medicine gives way to the itinerant vender, and yields the latter the field. The frontispiece with its remarkable coloring, is not calculated to increase respect for its scientific accuracy. Cobalt lungs, Venetian-red colon, Gamboge small intestines and raw umber livers may be picturesque, but scarcely natural.

Publications du Progres Medicales. Traitement des Maladies des Femmes par l'Electricité par le Dr. L. B. REGNIER, etc. Précédé d'une préface par le Dr. LABADIE-LAGRAVE, avec 32 figures dans le texte. 8vo, paper, pp. 303. Paris: Progrès Médical, 14 rue des Carmes; Felix Alcan, 108 Boulevard St. Germain.

There is no question now that electricity occupies a distinct place in gynecologic therapy, and it is the mission of such books as this of Dr. Regnier to assign its limitations and fix the measure of its usefulness. "The idea of making electricity useful in therapeutics," says Dr. Regnier, "is as old as its discovery, and the therapeutic applications have followed with equal pace the new discoveries which have been added little by little from the day of its study. If the applications of electricity to therapy have taken on to-day a very great extension, it is because electric science and physics has made very great progress in the last fifteen or twenty years."

The first part contains five chapters: namely, 1, Historic Introduction; 2, Electric Methods Employed in Gynecology; 3, Gynecologic Instruments; 4, Process of Mensuration of Currents; 5, General Technique.

The second part has four chapters, viz: 1, On Diseases of the Vulva and Vagina, which is subdivided into sections describing the treatment of each of the diseases named, except the last, which deals exclusively with anomalies; 2, Diseases of the Uterus; 3, Diseases of the Ovaries; 3, Diseases of the Tubes.

The third part of the book is devoted to disorders of the menstrual function and extra-uterine pregnancy. There has been a great deal of skepticism in this and other countries in regard to the curative influence, nay, even the beneficial influence of the electric current in many of these affections. We believe there is no doubt that the growth of myofibroma has in some cases been arrested and that in others the tumor has disappeared. Now, if even a reasonable proportion of these cases can be cured without a resort to the bloody, cruel and mutilating operation of hysterectomy, ought it not in all suitable cases to have a fair trial? There will remain enough hysterectomies after we have eliminated all that can be cured by electricity.

Occasional Papers on Medical Subjects, 1855-1896. By W. HOWSHIP DICKINSON, M.D., F.R.C.P. 8vo, cl., pp. 244. London, New York and Bombay: Longmans, Green & Co. 1896.

"The papers which have been brought together in this volume," says the author, "were written as opportunity occurred during the last forty years." Scattered among transactions and medical periodicals, the articles have not been generally accessible on this side. Several of them, however, are as well known in America as in England. The work is fairly illustrated. The contents are: 1, On the Action of Digitalis upon the Uterus; 2, Three Cases of Angina Pectoris, depending upon Occlusion of the Mouths of the Coronary Arteries; 3, Perforation of the Sigmoid Flexure of the Colon, probably due to the Irritation of Feces; 4, On the Changes in the Nervous System which follow the Amputation of Limbs; 5, On Counter irritation, considered in reference to the remote and indirect Effects of local and morbid Changes; 6, On the Enlargement of the Viscera which occurs in Rickets; 7, On the morbid Effects of Alcohol, as shown in Persons who Trade in Liquor; 8, On the Pathology of Chorea; 9, On Chorea with reference

to its supposed Origin in Embolism; 10, Cirrhosis of the Liver in Childhood; 11, Hereditary Albuminuria; 12, On Albuminuric Ulceration of the Bowels; 13, Places and Commonplaces in Renal Disease; 14, Lecture on the Cardio-vascular Changes of Renal Disease, with some Observations on the larger Arteries; 15, The Practice of Medicine at St. George's Hospital Forty Years Ago; 16, On the Presystolic Murmur falsely so-called; 17, Alkalies in Rheumatism.

Dr. Dickinson's admirers, and they are many, will be pleased to see this collection of essays in this form.

Transactions of the Chicago Pathological Society, from October 1894, to November 1895. Volume I. Chicago. AMERICAN MEDICAL ASSOCIATION Press, 1896.

This is one of the most active medico-scientific bodies of Chicago, and its proceedings are always of interest. Our readers will recall that of the papers have appeared from time to time and enriched the pages of this JOURNAL. The Publication Committee have done well to place them in book form for preservation. The many rare and important specimens described in these "Transactions," make the work one of great value and of enduring interest.

A Pictorial Atlas of Skin Diseases and Syphilitic Affections. In Photo-Lithochromes from Models in the Museum of the Saint Louis Hospital, Paris, with explanatory wood cuts and text by ERNEST BESNIER, A. FOURNIER, TENNESON, HALLOPEAU, DU CASTEL, with the coöperation of HENRI FEULARD and L. JACQUET. Edited and annotated by J. J. Pringle, M.B., F.R.C.P. London: The Rebmman Publishing Co. Ltd. Philadelphia: W. B. Saunders.

The fasciculus under notice is part third of this useful work. The design of the authors, Publisher and Translator is to make the models in this famous museum the common property of the profession. The work proceeds slowly, but with care and faithful closeness to the originals. We have in this number reproductions in photo-lithochrome of the models showing Tertiary Syphilitic Ulceration of the Tongue; Dermatitis Herpetiformis in Concentric circles; Syphilitic Gumma of the Thigh; Disseminated Epithelioma of the Face, sebaceous in type at the outset, with various intermediate types.

The explanatory text is quite remarkable for conciseness, the lessons are mainly told by the pictures themselves, and the reader is not wearied by tedious discussions, but enough is said for full understanding of the models.

Diets for Infants and Children in Health and in Disease. By LOUIS STARR, M.D. Philadelphia: W. B. Saunders, 1896. Flexible covers. Price, \$1.25.

This is a handy book of blanks, on which the physician may write the directions for the diet and regimen of his infant clientelage, tear them out and deliver to the nurse as often as required. It is not only a labor-saving appliance, but there are a few pages at the end containing printed directions for the preparation of diluents and foods, which may also be removed and handed to the nurse. In the management of children, the control and regulation of the diet is of the utmost consequence, and a carefully prepared list with directions, such as is found in this book, will be found very useful by all general practitioners and as well by those whose practice is exclusively confined to pediatrics.

Cerebral Hyperemia the Result of Mental Strain or Emotional Disturbance, the so-called Nervous Prostration or Neurasthenia. By WILLIAM A. HAMMOND, M.D., 2d edition. Washington: Brentano's, 1895. 16mo, cl., pp. 118.

The first edition of this book was published nearly twenty years ago, and found a place in the library of nearly every progressive physician soon after publication. Time has made no modification in the well-known views of the author, so far as the causes, symptoms and pathology are concerned, but the chapter on treatment has been augmented by the addition of statements concerning the use of animal extracts and certain new therapeutic remedies not known when the original work was issued.

How to Feed Children, a Manual for Mothers, Nurses and Physicians. By LOUISE E. HOGAN, Philadelphia: J. B. Lippincott Co., 1896. 12mo., cl., pp. 236. Price \$1.00.

This little book contains the substance of papers on the subject that have appeared in sundry magazine articles during the past year, and a great many facts culled from the latest editions of the standard authors. The advice given is sound, and the general principles of dietetics adhered to throughout. We commend the book.

A Manual of Anatomy. By IRVING S. HAYNES, Ph.B., M.D. Illustrated. 8vo. cl., pp. 680. Price \$2.50. Philadelphia: W. B. Saunders, 1896.

This is an excellent hand-book of regional anatomy. Osteology is omitted. The contents are: The head, anterior; the neck, anterior; head and neck, posterior; the brain; the upper extremity and thorax, anterior; the upper extremity and thorax, posterior; spinal cord; spinal nerves; the perineum, male; the perineum, female; the abdomen, exterior; the abdomen, interior; the lower extremity, anterior; the lower extremity, posterior. The illustrations are mostly photographs of dissections of the regions as explained in the text. The index is full and complete.

ASSOCIATION NEWS.

Second Pan-American Medical Congress.

PHILADELPHIA, PA., May 23, 1896.

To the Editor: Please announce to the profession that it is important for all who propose to attend the Second Pan-American Medical Congress to be held in the City of Mexico, Nov. 16 to 19, 1896, to inform me early in order that arrangements may be made with the railroads for transportation, and that the Secretary in Mexico may be properly informed as to the number likely to attend. It is necessary to have full information three months in advance, in order to arrange with the railroads. I will shortly send you a form for the certificate to issue to those who desire to go as delegates. I think also it will be well for me to issue a general circular to the societies urging them to appoint delegates.

I am glad to announce that I have received replies from Senator M. S. Quay, Congressman Robert Adams, Jr., Senator McMillan and from the Commissioners at Washington, all of whom appear to be impressed with the justice of our request and will aid to defeat the obnoxious antivivisection bill.

Yours very truly,

WM. B. ATKINSON, M.D.

SOCIETY NEWS.

Medical Society of West Virginia.—The 29th annual meeting will be held at Wheeling, June 10, 11 and 12, 1896. Officers: President, J. A. Campbell, Wheeling; Vice-Presidents, Harriet B. Jones, Wheeling; B. M. Smith, Davis; V. T. Churchman, Charleston; J. H. Kelley, Parkersburg; Secretary, G. A. Aschman, Wheeling; Treasurer, J. W. Johnston, Davis.

Papers to be read: "An Interesting Case," by Thomas A. Harris, Parkersburg; "Whooping cough Pneumonia—its Etiology, Symptoms, Prognosis and Treatment," by W. W. Golden Elkins; "The Evolution of the New Physician," by C. F. Ulrich, Wheeling; "Should not Legislative Enactments Authorize the Revoking of the State Medical License," by J. C. Irons, Elkins; "Gunshot Wound of the Brain—Operation, Recovery," by H. Yokum, Beverly, and W. W. Golden, Elkins; "The Wheeling Smallpox of 1895—its Lessons," by S. L. Jepson, Wheeling; "Nature's Antiseptics," by J. Schwinn, Wheeling; "The Present Status of Gastrostomy," by F. J. L. Hupp, Wheeling; "Hysterical Analgesia," by C. C. Hersman, Pittsburgh, Pa. "Massage in Surgical Affections," by C. A. Wingerter, Wheeling.

Medical Society of New Jersey.—The 130th annual meeting will be held at Asbury Park, June 23 and 24, 1896. The pro-

gram will consist of "A Demonstration of Bassini's Operation," by S. E. Milliken, New York. Papers: "Clinical Observation. Referring to Auto-Intoxication of gastro-intestinal origin," by Philip Marvel, New York. Annual Address of the President, William Elmer, Jr., "The Relation of the Physician to Sanitary Science." "Fibroid Tumors of the Uterus—Obstructing Labor, Subsequent Disappearance of the Tumors—Remarks on Uterine Fibroids as a Complication of Pregnancy," by George H. Halleray. Discussion upon subject presented at last meeting, "Is the Therapy of Anti-toxin Serum, Nuclein Solution and Typhoid Extracts so fully established as to receive the Endorsement of the Profession." Alex. McAlister was appointed to take the leading part in the discussion. "Antisepsis and Antiseptics from the Standpoint of the General Practitioner," by C. R. P. Fisher. "Chloroform Narcrosis," by Floy McEwan, Newark. The officers are: President, William Elmer, Trenton; First Vice-President, T. J. Smith, Bridgeton; Second Vice-President, D. C. English, New Brunswick; Third Vice-President, C. R. P. Fisher, Bound Brook; Corresponding Secretary, E. L. B. Godfrey, Camden; Recording Secretary, William Pierson, Orange; Treasurer, Archibald Mercer, Newark; Standing Committee: H. W. Elmer, Bridgeton; Henry Mitchell, Asbury Park, and H. G. Wetherill, Trenton.

Connecticut State Medical Society.—The 104th annual session of this society was held at New Haven, Conn., May 27 and 28. Dr. Seth Heill of Stepney, President. Amendments to the Medical Practice Act were proposed and accepted and the committee instructed to take measures to have them adopted. Section 8 provides that no person whether a graduate or not shall practice medicine in the State without a certificate from the examining committee. Officers elected for the ensuing year were: President, Rienzi Robinson of Danielson; Vice-President, Ralph S. Goodman, Thomaston; Secretary, N. E. Wordin, Bridgeport; Assistant Secretary, Julian La Pierre, Norwich; Treasurer, W. W. Knight, Hartford.

The Indiana State Medical Society held its forty-seventh annual meeting at Fort Wayne, Ind., May 28 and 29, with about 200 delegates in attendance. Dr. M. F. Porter of Fort Wayne presided. Before adjournment the convention introduced a resolution to memorialize congress against the passage of the antivivisection bill.

The following officers were elected for the ensuing year: President, J. H. Ford, Wabash; Vice-President, W. A. Batson, Ladoga; Secretary, F. C. Heath, Indianapolis; Assistant Secretary, Dr. Rooker of Shelbyville; Treasurer, A. C. Bukon, Fort Wayne. The next annual meeting will be held at Terre Haute.

Ohio State Medical Society.—The following are the officers recently elected: President, Dr. F. C. Larimore, Mt. Vernon; First Vice-President, Dr. M. Stamm, Fremont; Second Vice-President, Dr. C. F. Clark, Columbus; Third Vice-President, Dr. John S. Beck, Dayton; Fourth Vice-President, Dr. Geo. W. Crile, Cleveland; Secretary, Dr. Thomas Hubbard, 205 Ontario St., Toledo; Assistant Secretary, Dr. H. M. W. Moore, Columbus; Treasurer, Dr. J. A. Duncan, Toledo. Next place of meeting, Cleveland, the third Wednesday, May, 1897.

Missouri State Medical Association.—The Medical Association of the State of Missouri held its thirty-ninth annual session in Sedalia, Mo., May 19 to 21, with Dr. C. Lester Hall, Kansas City, presiding. There were about 300 delegates in attendance. Among the papers read were the following: "Report on Progress of Serum Therapy," by Dr. John M. Langsdale, Kansas City; "Diphtheria," by Dr. J. M. Allen, Liberty; "Intestinal Auto-infection," by Dr. S. G. Gant, Kansas City; "Curative Effects of the Toxin Treatment in Cancer," by Dr. G. Wiley Brown, St. Louis; "The Early Diagnosis and Treatment of Certain Lung Diseases," Dr. Paul Paquin, St. Louis; "Importance of Early Diagnosis of Tuberculosis of Bone," by Dr. George Halley, Kansas City; "Cerebral Embolism, Presenting Pathologic Specimen," by Dr. Brummell Jones, Kansas City; "A Case of Original Paranoia," Dr. A. E. Mink, St. Louis; "Additional Case of Friederich's Disease," Dr. F. R. Fry, St. Louis.

The following officers were elected for the ensuing year: President, Dr. John H. Duncan, of St. Louis; First Vice-President, Dr. C. H. Walton, of St. Joseph; Second Vice-President, Dr. J. M. Langsdale, of Kansas City; Third Vice-President, Dr. J. J. Russell, of California; Fourth Vice-President, Dr. Thomas Chowning, of Hannibal; Fifth Vice-President, Dr. J. H. Britts, of Clinton; Recording Secretary, Dr. J. M. Jackson, of Kansas City; Assistant Recording Secretary, Dr. Thomas Hall, of Marshall; Corresponding Secretary, Dr. A. F. Dresel, of Sedalia; Treasurer, Dr. W. E. Evans, of Boonville.

NECROLOGY.

J. H. LEDLIE, M.D., one of the oldest physicians in Pike County, died at Pittsfield, Ill., May 25. He graduated from the Royal College of Physicians and Surgeons, at Dublin, Ireland, in 1854, and came to America the same year. He located in Pittsfield in 1858, and enlisted in the 98th Illinois Volunteers August, 1862, as surgeon, and at the close of the war was mustered out with the rank of lieutenant-colonel.

J. T. PEARMAN, M.D. (Rush Medical College, Chicago, Ill., 1868), in Champaign, Ill., May 25, aged 66 years. He has been a resident and prominent citizen of Champaign for thirty-five years. He served in the civil war as surgeon of the 15th Indiana Volunteers, and was a trustee of the University of Illinois from 1881 to 1887.

D. W. CARLEY (Rush Medical College, Chicago, Ill., 1856), May 27, of Bright's disease. He was one of the oldest residents and physicians in the State, and was a surgeon of volunteers in the late war.

W. R. ROBINSON, M.D. (Chicago Medical College, Chicago), at Macomb, Ill., May 24, of erysipelas.

MISCELLANY.

University of California, Medical Department.—The commencement exercises of this college, San Francisco, were held May 22. Seven women and forty-two men received their diplomas.

The Fourth International Congress of Hydrology, Climatology and Geology will be held this year at Clermont-Ferrand, among the picturesque scenery and mineral springs of the Cevennes region. The opening day is September 28.

Gonorrheal Epidemic.—At a recent medical meeting at Riga, the infection was reported of 326 girls, from 4 to 16, traced to the use of a common bathroom, where all contracted blennorhea urethralis.—*St. Peters. Med. Woch.*, April 18.

Official Investigation of the Contagiousness of Tuberculosis in Hospitals.—The authorities of Paris have appointed a committee consisting of twenty-two of the best known physicians and city officials to investigate this subject and determine the preventive measures to be taken, if it is found they are needed.

Fetid Endometritis of Elderly Women.—Maurange has had several cases of fetid discharges, inflammation and hemorrhages, presenting the exact picture of an uterine cancer, which he has simply treated locally with creasoted glycerin after dilating the cervix and tamponed with gauze. A few of these disinfecting treatments produced a complete cure. He warns against confounding this endometritis after the menopause with a cancer, from which it is only to be differentiated by histologic examination. *Gazette Méd. de Paris*, May 9.

Effect of Acoustic Sensations on the Pulse and Respiration.—Following the suggestions in the works of Mosso and others, and using a sphygmograph and pneumatograph similar to Marey's, with a noiselessly revolving kymographion, a series of experiments in Wundt's laboratory have established the fact that pleasurable acoustic sensations sensibly retard the pulse and respiration for a time, while unpleasant sensations accelerate them. As pleasure changes to annoyance from repetition, the slower pulse and respiration change to faster. The reverse is the case when voluntary attention changes into involuntary, the pulse then grows slower to normal or even slower than normal. *Centralblatt f. Physiologie*, April 4.

European Approval of American Laws in Regard to the Ophthalmia of the Newborn. The Société d'Ophthalmologie has been having its annual congress at Paris, May 4-7, and Lucien Howe, of Buffalo, described our laws to prevent blindness from this cause. The association regarded them with favor, and several urged their adoption in France. All agreed that attending

physicians and midwives must be made to realize their great responsibility in this respect, more than some of them do at present. The suggestions of "*Docteur Buffalo*" are being quoted with approving comment in many of our foreign exchanges.

The National Medical Review of Washington is now "the official journal of the Medical Society of the District of Columbia." All papers and discussions that are given before that society will be published in the official journal. This society now has about three hundred active members, and includes a number of the most prominent medical men in the army and navy. The editor announces that his journal will be enlarged and otherwise greatly improved, in order to carry into effect this new arrangement.

Recovery from Mænnlicher Bullet Wound in the Head.—The *Cronica Médica* of Feb. 15, describes a double trephining performed on a soldier wounded at the time of the attack on Lima about a year ago, followed by complete recovery although the bullet had passed through the right parietal region, penetrating the bone and producing absolute hemiplegia, convulsions, etc. Dr. Olochea notes in his report the efficacy and harmlessness of exploratory punctures in such cases, and the great benefits to be derived from muriate of ammonia in cerebral contusions. It cured in this case the first paralysis of the left arm, until the increasing inflammation produced general hemiplegia.

Still another Method of Extirpating Cancer of the Breast.—Tansini of Palermo describes his method in the *Riforma Médica*, No. 11, which he asserts will prevent future relapses. He makes a pear-shaped incision, the large end embracing the breast and the small end terminating in a couple of incisions meeting at the axilla. After the tumor is removed with the pectoralis major, he makes a similar incision in the back, and applies the flap thus procured to the open space in the breast. The flap cut in the back is raised except at the small end which reaches to the insertion of the latissimus dorsi. It is then applied to the open space in front, twisting it a little to bring it around in front over the wound. The edges are then sutured, and the edges of the wound in the back are pulled together, and also sutured, as can be readily done owing to the elasticity of the skin, a couple of liberating incisions being made if necessary.

The Cortical Mechanism of Reflex Phenomena.—Physiologic and pathologic research have convinced Pándi that it is incorrect to regard the brain as the center of intelligence of the so-called lower centers (including the spinal cord), as opposed to being the seat of reflex phenomena. It seems to him sufficiently demonstrated that the reflex phenomena of the intact organism, the rapid as well as the slow, are all accomplished by means of the cortex cerebri. He could not find a single physical or clinical fact to show that the sub-cortical substance was able to produce a reflex movement or even a tonus without abnormal stimulus. After complete severance of cortical communication the lower means of communication then act vicariously, and substitute all the functions of the brain, the lowest as well as the most complicated, but of course these functions never attain as high a degree of perfection as the cerebral.—*Centralblatt f. Physiologie*, April 4.

An Ambulance Surgeon Commended.—A Brooklyn citizen sends a letter to one of the papers in which he dispenses praise of one of a class that is more often blamed than praised in the public press:

Dear Sir—I take the liberty of writing to you to congratulate you and the citizens of Brooklyn on having in their employ a man of great force of mind and body. I refer to Ambulance Surgeon D., of the A. B. Hospital, who on last Wednesday evening succeeded, through true courage and skill, in saving the life of a little girl who fell into the water from Erie Basin dock. All signs of life were extinct to the eyes of the large crowd at hand, yet this gentleman, ignoring the cries of the

bystanders, kept steadily at work for twenty long minutes, when the child gasped; still working at the end of a half hour the child cried and was saved. Well did the doctor deserve the praise showered upon him, to have succeeded in reviving an apparently lifeless child. This gentleman deserves public commendation as a shining example of the typical saver of life. It would give me the greatest pleasure of my life to present him with a medal suitable for such a humane act.

Hematologic Study of Professional Fasting.—Succi has been fasting again in Vienna, at the "usual low price of admission," but the doctors have left him entirely alone. The *Klin. Rundschau*, however, publishes a study of his blood made a year or so ago by Professor Tauszk, which it commends to its readers on account of its timeliness and the difficult linguistics of the original in a Budapest publication. He found that during the thirty days of the fast the red blood corpuscles first decreased in number, but then afterward increased. The white corpuscles in general and the mononuclear cells diminished in numbers, while the eosinophilous and polynuclear cells increased. The blood became less alkaline. Ranke states that the number of red corpuscles in animals is less during their winter sleep, but Dupérier announces, on the other hand, that they increase in number in inanition, which coincides with the results of the above investigations. Succi lost 14 k.g. in weight during his fast.

"Disinterested Interest," a Lesson Learned at Atlanta.—A short editorial in the *Lehigh Valley Medical Magazine* indicates that the editor had an especially interesting and profitable visit to the Atlanta convention. He writes concerning the abandonment of selfishness by medical men when they go to medical congresses; everything should be done "by the good, with the good and for the best." The golden rule should be the manual of proceedings, and the avoidance of all self-seeking contentions the motive of every participant. He says:

To eliminate the element of personal benefit in our efforts for associated good is as difficult of accomplishing as it is desirable. While probably the majority of the six hundred or more registered at the Atlanta meeting had no personal axe to grind as far as the management of the Association is concerned, the most of them were unconsciously put to turning the grindstone. Now it is to favor a friend who wishes a friendly favor; again it is to favor a friend in order to, in some way, down his rival; or, it is to quietly make of another a cat's-paw. But, with all this, there was much of the laboring for the good for the good's sake; and the efforts in this direction are yearly becoming more apparent. The moral of the whole is for each member of the rank and file to think for himself and act upon his conclusions, whether in county, state or national organizations. The advantage to be gained should be a common advantage; the interest in the Association should not be because of self.

Colorado has Changed its "Gold Cure" Law.—In 1895 the general assembly of the State of Colorado repealed the "Gold-Cure-Institutes" law of 1893 and enacted a new law in its stead. The principal features of the latter are that a friend of a habitual drunkard, or any officer of any charitable organization may file a petition in the county court, setting forth the sex, financial condition, age, nature and extent of the disease of such drunkard in reference to the use of alcoholic, narcotic or other stimulants, and stating the belief of the petitioner person making affidavit that such disease has passed beyond the control of such drunkard, and asking for an order to send the latter to an institute for the treatment of such disease, at county expense. Such petition or affidavit shall be approved and signed by ten freeholders of the county. Five days' notice of the time of hearing thereon is to be served on the drunkard, unless the latter voluntarily appears. He must have been a bona fide resident of the county for at least six months preceding and consent to be treated and be financially unable to pay for the treatment. The county attorney is also to attend at the hearing on the petition. The institution to be selected, by the county judge, must be located in the state of Colorado, and show that not less than 75 per cent. of the persons who have been treated at it for drunkenness have been cured thereat for at least one year.

A New Preparation of Cannabis Indica.—The current number of the *American Therapist* has the following from the *Therapeutische Wochenschrift* for March 1. The writer mentions "a new watery fluid extract of cannabis indica, termed extractum cannabis indicæ aquosum fluidum, and states that, according to R. Cowan Lees, it possesses all the beneficial properties of the plant, but does not give rise to that state of intoxication, bordering on poisoning, which follows the use of even medium doses of the alcoholic preparations. It has no effect on the secretion of bronchial mucus, and consequently in suitable cases it seems more efficient than opium, and it has a manifest anodyne and hypnotic effect in pulmonary affections. Lees has observed the best results from its use in tuberculous disease of the lungs, in which it materially alleviates the paroxysms of coughing while at the same time it exerts the precious stimulating and cheering effects of cannabis indica. It is, furthermore, of value in digestive disturbances connected with constipation and as a soporific in the diseases of children. The medium dose for an adult is from thirty to sixty grains; for a child less than a year old, from fifteen to thirty one-hundredths of a grain for each month of age; for older children, from a grain and a half to three grains for each year of age."

Connection Between the Pancreas and Diabetes Mellitus.—Known to the ancients who gave it its name, it is only within the last few years that science has attained an insight into the causes of diabetes, through Minkowski's experiments on dogs, from which he announced that extirpation of the pancreas produces typical, fatal diabetes mellitus in all its progressive stages. Others have produced glycosuria with various experiments, notably Mering's diabetes produced by administering phloridzin to dogs. But this passes away with the suspension of the phloridzin, as is also the case with glycosuria produced by excesses of various kinds. The close connection between the pancreas and diabetes, is also shown by Hansemann's report on the necropsies made at the Pathological Institute at Berlin: Cases of diabetes without apparent pancreatic lesions, 8; cases of diabetes without information in regard to the pancreas, 6; cases of pancreatic lesions without diabetes, 19; cases of diabetes with pancreatic lesions, 40. All the latter but one showed general atrophy of the pancreas. Dieckhoff's seven necropsies of diabetics all showed atrophy, and in a recent case reported from New York, a typical diabetes supervened in a patient after extirpation of the pancreas. Wellberg adds that a transient or intermittent form of glycosuria is frequent and apt to be disregarded, but it should be carefully watched, as it is liable to lead to grave diabetes mellitus unless the diet is changed and other precautions taken, especially in cases where there is a tendency to obesity, gout or nervous troubles.—*St. Petersburg Med. Woch.* of April 18.

Presumption as to Trade Marks on New Inventions.—With the aid of a physician, the party who was plaintiff in the case of Shaw v. Pilling, which was decided by the supreme court of Pennsylvania April 13, 1896, invented an atomizer, and although he did not, and perhaps, not being the sole inventor, could not, patent it, he adopted and attached the name of his partner, Burgess, to distinguish his make of atomizer. It was the defendant's error or misfortune to have assumed that this was a case within the imperative rule of ethics, enforced as a by-law of the College of Physicians of Philadelphia, and declared by the supreme court of Pennsylvania to be highly honorable to the medical profession, that a physician who discovers a remedy, or a surgeon who invents or improves an instrument, does not take a patent or trade mark for it, but dedicates it at once to the service of humanity, and though it may become known by his name, it is, nevertheless, free for all to use, and the name is regarded as merely descriptive of the article. They sought to avoid the consequences of their mistake of fact (assuming that it was innocent) by showing that other dealers made the

same mistake, and they asked the trial judge to say that, under the circumstances, the plaintiff could not appropriate a descriptive name of this kind as a trade mark. But the supreme court says that a man's property is not to be taken away so easily. The descriptive name of the instrument was an atomizer. That was public property, and could not be appropriated as part of a trade mark by any one. But when the inventor and manufacturer of a new kind of atomizer put his own or his partner's name to it, the court holds that the presumption was that he did so to indicate the origin and maker, and intended the name as a trade mark: that defendants and some other dealers misunderstood the facts was not sufficient to excuse a violation of plaintiff's rights.

Study of Diuretics.—Sobieranski presents the results of a series of experiments in the line of Ludwig's theory of urinary secretions. Animals killed at various intervals after the injection of indigo-carmin, showed that the substance was secreted by the glomeruli alone, and only absorbed by the convoluted tubules. After injections of carmin-sodium, it was never found in the basal epithelium of the convoluted tubules, which proves again that this epithelium does not secrete. Further experiments proved that after the administration of diuretics, and while the system is fully under their influence, the injection of indigo-carmin varies in its effects. With caffeine the cells of the convoluted tubules were no longer stained, only a weak coloration here and there in the secreting epithelium, which he explains by the assumption that caffeine paralyzes the absorbing power of the convoluted tubules and to this he ascribes its diuretic action. The diuretic salts, sodium chloride, nitrate and acetate, produce their effect through the blood increasing the secreting power of the glomeruli while only slightly affecting the absorbing function of the tubules. Urea and kindred substances stand between these, as they raise the osmotic co-efficient of the glomeruli on one hand, while they diminish the absorbing power of the convoluted tubules on the other.—*Centralblatt f. Physiologie*, April 4.

Dissatisfaction in the British Army Medical Staff.—A Brigade Surgeon of over thirty years' service, makes known the grievances of the Army Medical Officer in a letter to the *Lancet* of May 9, 1896. He defends the professional status of the members of the medical staff affirming that in all the wars of the last forty years they have shown themselves to be not only good officers but good medical men: and that in peace time the results of practice in military hospitals compare favorably with those of civil hospitals, so that the soldier has little to complain of in this regard, although it is a well recognized fact that medical advice which is obtained for nothing is very lightly regarded by all classes. The effort to degrade them by depriving them of military rank is the main subject of dissatisfaction. Not that medical officers are ashamed of the title of doctor or are in the least degree desirous of being taken for combatant officers, but as they lead an entirely military life, accompanying the soldier on all his campaigns, sharing to the full his hardships and dangers for however big or small the expedition may be if it involves a risk to the soldier, there is found the army surgeon ready at hand to afford help in case of need—they are military men in every sense of the word, though not combatant officers and naturally desire to possess military titles which show, not to military men only, but also to civilians with whom they associate what rank they have earned and hold in the army. Such titles as were formerly in use do not convey this information; nor were they ever used except officially. A surgeon of one month's service and an inspector general of thirty-five years active service were both addressed simply as "doctor." They object to this. The Brigade Surgeon cited is convinced that the endeavor to deprive army surgeons of their military rank earned by hard service in the field and to make them, as General Buller expressed it in his recent

speech at Netley, merely an annex to the army, is at the bottom of the prevalent discontent, and until this is removed good men will not be induced to join the Army Medical Department.

Practical Notes.

Smoker's Gingivitis.—Vian recommends to rinse out the mouth with a teaspoonful of the following mixture in half a glass of warm water: Salol, 1 gm.; spirit. menth. pip., 100 gm.; tinct. catechu, 4 gm. Use externally.—*Memorabilien*, April.

Marchal's Process of Preserving Instruments from Rust.—A very small amount of alkali is sufficient to keep metal from rusting, so that if steel, iron, nickel or copper instruments are dipped in five grams alcohol containing one or two grams of either borate, carbonate, bicarbonate or benzoate of soda, they will not tarnish.—*Gaz. Méd. de Liège*, May 14.

Two Cases of Rupture of the Uterus.—Chéron, in the *Bulletin Médical*, April 22. In one case the child was found at the necropsy in the peritoneal cavity, its head under the left false ribs, the thighs in the uterus and its feet in the vagina. The promonto-pubic diameter of the pelvis was only six centimeters. In the other case there was shoulder presentation, and the lower segment of the uterus was torn, the peritoneum not affected. The case at first went well, but death followed from peritonitis a week later.

Hydatic Cysts in Both Fallopian Tubes.—Doleris has collected eighty observations reported of hydatic cysts in the true pelvis, but none mention their origin. He had a case recently where the operation revealed a long tumor, filling both tubes, which were contorted. The enucleation was very difficult, and the uterus had to be removed in order to be sure that all the tumor was extirpated. Doleris mentions that the patient was the wife of a butcher, and constantly surrounded by dogs.—*Bulletin Médical*, April 22.

A Case of Biliary Calculi with Rupture of the Gall Bladder.—Schabad describes in the *St. Peters. Med. Woch.* No. 3, the case of a young woman who showed suddenly symptoms of acute peritonitis, with a sensitive area in the abdomen and perforation of the anterior wall of the rectum, death ensuing in twenty-five days. The necropsy showed general non-suppurating peritonitis; among the intestines were found three calculi the size of a walnut: the gall bladder had been ruptured and a couple of calculi protruded from it. The case is instructive, as it shows that an operation, even after perforation, might have resulted favorably. Few cases of ruptured gall bladder survive so long.

Berger's Study of 10,000 Cases of Hernia.—This work of 204 pages just published in Paris, contains the results of an amazingly thorough and detailed investigation of 10,000 cases, with full particulars as to age, sex, occupation, etc. The work was all done in Paris, and therefore the author's conclusions are misleading, if applied to places where such supreme facilities for prompt treatment and procuring of proper bandages, etc., do not exist. He states, for instance, that irreducible hernia only occurs once in 28.8 cases, and that strangulation and peritonitis occur in only 6.45 per cent. of the cases of femoral hernia, in 1.91 per cent. in umbilical hernia, and in 1.43 per cent. inguinal hernia.—*Centralblatt f. Chirurgie*, May 2.

Regeneration of Extirpated Exophthalmic Goitre and Section of the Cervical Sympathetic. Partial excision of bronchocele is usually followed by the subsidence of the remaining part, but Jaboulay describes a case of exophthalmic goitre in which he had removed the growth five times in the last three years, with constant regeneration of the extirpated tissue. Finally he decided upon section of the sympathetic, between the first and middle cervical ganglia. The immediate result was favorable the exophthalmus, tremor and palpitations ceased, but in three or four weeks the two latter returned. He explains this by the fact that the fibers for the peri- and intra-ocular muscles were

rendered functionless, but not those for the accelerans cordis, which does not connect with the sympathetic, but with the rami communicantes through the ganglion inferius. He therefore suggests, to ensure the cessation of the palpitations, that the branches of this ganglion should be cut, but the ganglion itself must be left undisturbed, as it is a trophic center.—*Centralblatt f. Chirurgie*, May 2.

Somatose.—Since Hildebrandt announced the virtues of somatose at the Wiesbaden Congress of 1893, it has come to be appreciated by many, who estimate it as far more valuable than the preparations of peptone. Scognamiglio has been making a series of tests to determine its exact effect on the composition of the blood. His subjects were three chlorotic patients who showed each by the Thoma-Zeiss method a remarkably small number of red corpuscles with a large excess of leucocytes. No other treatment was given, and the number of blood corpuscles was counted at intervals of five days. They showed a steady increase, amounting to 4,500,000 per c.cm. at the end of a couple of months. The number of microcytes and poikilocytes also diminished. At first the amount of hemoglobin was only 8.9 per 100 c.cm., but this amount rose to the normal 13.5 to 14.5 per cent. The *Wiener klin. Rundschau*, March 15, closes its notice of this study with the remark that it demonstrates once more the fact that in somatose we have a preparation of "inestimable value."—(See *Riv. Clin. e Terap.*, February, 1896.

Total Amputation of the Tongue by the Transhyoid Method.—Vallas, of Lyons, recently removed a cancerous tongue as follows: 1, preliminary ligature of the two lingual arteries, thus preventing hemorrhages and the necessity of tracheotomy; 2, osteotomy of the hyoid bone (see *Prov. Méd.*, January); 3, removal of the mucous membrane of the mouth through the mouth, the whole length of the inner side of the inferior maxillary bone; 4, the tongue is grasped with the forceps, through the hyoid wound, and brought down and out through it; 5, two strokes of the scissors, following on each side the upper edge of the hyoid bone, detach the hyoglossus and complete the section of the base of the tongue. By this process the tongue is cut out its entire length. A coarse thread passed through the roof of the mouth on each side helps to close the large opening left and favor the reconstitution of the mylohyoid tissue. Vallas adds that the median section of the hyoid bone is not followed by any trouble in breathing, as he has already performed many similar operations. In the case above the patient can talk, only he can not utter the lingual syllables. He swallows without difficulty since the wound has healed.—*Province Médicale*, March 14.

Sudden Death in a Case of Fracture of the Patella—Dangers of Massage.—According to *La Médecine Moderne*, Dr. Cerne has had an unexpected fatality in a case of simple, transverse fracture of the patella, with little separation of the fragments and but slight effusion into the knee joint. The effusion soon disappeared. At the end of three weeks the patient, who was strong, active and of good constitution wished to know when he could rise and leave the hospital. He could easily raise his limb from the bed. There was some motion, but limited, in the knee joint. The leg, however, was clammy, both above and below the articulation. The surgeon intended to apply a silicate dressing, but was desirous first of facilitating the absorption of the exudate, of promoting the nutrition of the quadriceps (which, according to most authors, atrophies), and of rendering the joint somewhat mobile. He accordingly prescribed gentle massage to the thigh, as was his usual custom. There was at this time no appreciable pain in any part of the limb. Massage had been practiced on several occasions, particularly on one day, when on the next the patient was suddenly seized with suffocation and died within a few minutes. At the autopsy the pulmonary artery was found obliterated by

large thrombi derived from the deep femoral vein. It is not possible to demonstrate that massage brought about this result. Nearly twenty-four hours had elapsed since this massage had last been performed, but it is highly probable that the practice was what determined the migration of a clot, and that this was done by the breaking up of the femoral thrombus.

On the Non-Irritant Use of Boric Acid Solutions.—Dr. John E. Bacon, of Buffalo, writing to the *American Therapist*, commends boric acid to a higher confidence among the profession as meeting all indications for a non-irritating antiseptic quite as well as most of the elaborate and expensive compounds now being pushed by our enterprising manufacturing chemists for recognition by the profession. With care in its use, especially in respect to its proper dilution, the remedy is destined to go to the front. He offers the following formula and suggestion for the avoidance of unnecessary irritation: "After an extended trial of many formulæ for nasal sprays the writer has concluded that the vast majority of them are too irritating to be used in any but atrophic cases, in which a moderate amount of stimulation is useful. After spraying a hypertrophic case or a normal nose with Seiler's solution, for instance, a copious mucous discharge will be excited and continue for an hour, showing the irritating action of the spray. Boric acid in saturated solution is slightly irritant to the nasal membranes, but is not in solutions of less strength; for example, a formula like the following will be soothing to an inflamed membrane and non-irritating, while it is just as useful for cleansing purposes: Acid boric, gr. v; sodii bicarb., gr. v; glycerin, ʒi; aquæ dest., q.s. ad ʒiii. M. Sig.: To be used in atomizer after being warmed."

Detroit.

A NEW CHEESE PTOMAIN.—A semi-official announcement says that Dr. V. C. Vaughan, Ann Arbor, and assistants have extracted a new ptomain from poisonous cheese.

THE MEDICAL MEN OF THIS CITY organized themselves into a league some time ago and on May 21 they perfected their organization. The purpose of the league is to draft a bill and to influence legislation to get the same passed and signed by the Governor, that will debar from practice in this State all who attempt to come here and practice without due qualifications. The following officers were elected: Dr. E. L. Shurly (R.), President; Dr. E. S. Sherrill (R.), Corresponding Secretary; Dr. S. H. Knight (H.), Recording Secretary; Dr. D. F. W. Robbins (R.), Treasurer; Executive Board, Drs. J. H. Carstens (R.), R. C. Olin (H.), D. A. MacLachlin (H.), H. J. Mulheron (R.), E. H. Covey (E.). It will be observed that in this list all schools are represented. There will be ten vice-presidents, to be appointed by the executive board. The next meeting of the organization will be held some time in June.

WAYNE COUNTY MEDICAL SOCIETY.—Thursday, May 28, this society held its last regular weekly meeting until after the summer holidays, the next meeting being September 3.

AT THE REGULAR MEETING of the Detroit Medical and Library Association, held Monday, May 25, Dr. Delos Parker read a paper entitled, "A Few Ideas Concerning Chloroform and Ether."

HEALTH OFFICE report for week ending May 30, 1896: Deaths: total 64; under 5 years 30; births, male 53, female 46, total 99. Contagious diseases: diphtheria, last report 13, new cases 9, recovered 3, died 2, now sick 17; scarlet fever, last report 19, new cases 8, recovered 3, died 1, now sick 17; measles, last report 7, new cases 1, recovered 5, now sick 3.

Louisville.

INFIRMARY.—Articles incorporating the "Gray Street Infirmary" have been recently filed with the county clerk. The incorporators are the members of the faculty of the Hospital College of Medicine, the Medical Department of Central University. The officers are: President, Frank C. Wilson; Vice-President, S. G. Dabney; Secretary, J. E. Hays; Treasurer,

H. H. Grant. The indebtedness is not to exceed \$15,000. The object of the infirmary is to maintain an institution for the treatment of all diseases, the care of the sick and the distribution of medicine. There is no capital stock and there will be no pecuniary benefit derived.

VISITING STAFF.—The Board of Safety has made its annual report as to the visiting and consulting staff at the City Hospital under its control. Quite a sensation was created among the profession when they announced that hereafter the Kentucky School of Medicine would not be recognized in the appointments; the rule heretofore being that each school was entitled to representation on the staff, for three months in the year and the non-school men to the rest of the year. The appointments made did not include any of the Kentucky School faculty, the reason being that, as stated by the board, it had not taken out the regular number of tickets to clinical lectures during the past year: the appointment of a resident at the Hospital from the graduating class at the Kentucky School would also not be recognized. This injustice called forth a merited rebuke from the faculty of the Kentucky School, and when it was shown that each member of the graduating class had his hospital ticket, and that the decrease in numbers was the result of the enforcement of the longer term, the school was recognized and appointments will be made as heretofore.

NURSES.—The annual commencement of the Louisville City Hospital Training School for Nurses was held in the amphitheater of the hospital on the 22d ult., diplomas being bestowed on eight graduates. Addresses were made by Dr. Louis Frank and by Dr. George W. Griffiths, and the diplomas were presented by his honor, the Mayor.

DR. JNO. A. OUCHTERLONY has been confined to his bed with sickness for several weeks past but is much improved at this writing.

STATE MEDICAL SOCIETY.—The annual meeting of the State Society to be held in Lebanon on June 10, 11 and 12, bids fair to be one of the largest meetings in its history. The subjects chosen for discussion this year are "Bright's Disease" and "Fractures," with a number of papers bearing upon each subject, and beside a number of interesting papers will be read on other subjects. The chairman of the committee of arrangements has done his duty well and the meeting is expected to be a notable one in every respect. The meeting will be presided over by Dr. Jno. A. Lewis, of Georgetown. The program will be issued by June 1.

THE PUBLIC SERVICES.

Vacancies in the Medical Corps of the U. S. Army.—There are at present three vacancies in the Medical Corps of the U. S. Army, and it is expected that at least three more will occur during the present year. As usual, an Army Medical Board will meet in Washington early in October for the examination of candidates. The requirements for admission to the Medical Corps are stated in a Circular issued by the Surgeon-General of the Army, dated May 21, 1896, and approved by the Secretary of War, as follows:

"Permission to appear before the Board is obtained by letter to the Secretary of War, which must be in the handwriting of the applicant, giving the date and place of his birth and the place and State of which he is a permanent resident, and inclosing certificates, based on personal acquaintance, from at least two reputable persons as to his citizenship, character and habits. The candidate must be a citizen of the United States, between 22 and 29 years old, of sound health and good character, and a graduate of some regular medical college, in evidence of which his diploma will be submitted to the Board. The scope of the examination will include the morals, habits, physical and mental qualifications of the candidate, and his general aptitude for service; and the Board will report unfavorably should it have a reasonable doubt of his efficiency in any of these particulars.

"The physical examination comes first in order, and must be thorough. Candidates who fall below sixty-four inches in height will be rejected. Each candidate will also be required to certify that he labors under no mental or physical infirmity or disability which can interfere with the efficient discharge of any duty which may be

required." Errors of refraction, when not excessive, and not accompanied by ocular disease, and when correctible by appropriate glasses, are not causes for rejection.

"The mental examinations are conducted by both written and oral questions, upon:

"I. Elementary branches of a common school education, including arithmetic, the history and geography of the United States, physics, ancient and modern history and general literature. Candidates claiming especial knowledge of the higher mathematics, ancient or modern languages, drawing, analytic chemistry or branches of natural science, will be examined in those subjects as accomplishments and will receive due credit therefor according to their proficiency.

"II. Professional branches, including anatomy, physiology, chemistry, hygiene, pathology and bacteriology, therapeutics and materia medica, surgery, practice of medicine, obstetrics and the diseases of women and children.

"Examinations will also be conducted at the bedside in clinical medicine and surgery, and operations and demonstrations will be made by the candidates upon the cadaver.

"Hospital training and practical experience in the practice of medicine, surgery and obstetrics are essential to candidates seeking admission to the Medical Corps of the Army, who will be expected to present evidence that they have had at least one year's hospital experience or the equivalent of this in practice.

"To save unnecessary expense to candidates, those who desire it may have a preliminary physical examination and a mental examination in the elementary branches of a common school education, by a medical officer of the Army stationed most conveniently for this purpose, who will act under instructions from the Medical Examining Board."

Army Changes. Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from May 23 to May 29, 1896.

First Lieut. Benjamin Brooke, Asst. Surgeon, is granted leave of absence for four months, on surgeon's certificate of disability.

Capt. Ashton B. Heyl, Asst. Surgeon, the order assigning him to duty at Ft. Canby, Washington, is revoked; he is relieved from duty at Ft. Thomas, Ky., and ordered to Ft. Riley, Kan., for duty, relieving Capt. Thomas U. Raymond, Asst. Surgeon. Capt. Raymond, on being thus relieved, is ordered to Ft. Canby, Washington, for duty.

Change of Address.

Burns, R. J., from Chicago, to Box 172, Rockford, Ill.
Caldwell, J. R., from Chicago, Ill., to West Liberty, W. Va.
Dillard, B. A., from D'Arbonne, La., to Garrison, Tex.
Guthrie, F. A., from Chicago to Aledo, Ill.
Krause, A., from Chicago, Ill., to Tripp, So. Dak.
Kirkpatrick, C. D., from Centerville to Rutledge, Mo.
Kors, M. L., from Chicago to Virginia, Ill.
Larsen, L. A., from Chicago, Ill., to Colfax, Wis.
